Vol. XI.

COLOMBO, JULY 1ST, 1891.

[No. 1.

"CORNERING" CEYLON TEA.

WE must await fuller details than those furnished by our London Letter as to Mr. Elwood. May's scheme for the distribution of our teas before we can venture to decide fully with respect to

it. So far as we can form an opinion upon our correspondent's abstract of that gentleman's letter, we should be disposed to adopt the view already taken of it in London. In the first place, we have always expressed ourselves—as we have felt—to be strongly opposed to the practice universally known by the term of "cornering" which Mr. May apparently suggests. We hold it to be not only opposed to the true principles of genuine trading; but, owing to the ill-effect it has upon thousands of people, to be morally indefensible. Against monopolies of all sorts—especially when they are resorted to by Governments—the public sense of modern days revolts. We do not say that they are absolutely indefensible. In some instances, as in that of our own salt trade, they may be indispensable as a means of securing the cheap and regular distribution of an indispensable food article, as well as of raising revenue, though we could perhaps wish that that and similar forms of taxation could be abolished and compensated for in some other way.

But apart altogether from objections of this nature, to the monopoly in dealing with Ceylon tea which it seems to be Mr. May's desire to create, there is the fact of the utter impracticability of accomplishing the end in view. When first our island grown teas attracted notice, and when there appeared to be great difficulties in the way of making them popularly known in the countries of consumption, it seemed to many of us that it might be both necessary and desirable to establish agencies having

the imprimatur of our Planters' Association. It is some central control of that kind which it seems to be Mr. May's desire to establish now. But the day for this has gone past, and it is singular that the fact has not been realised by the President of the American Company established for the sale of our teas throughout that vast continent. We could not, did we desire to do so now upset the manifold private agencies which have been established, and which have already had such a marvellous effect in widening the area of the sale of our teas throughout the United Kingdom.

We do not understand Mr. May to intend to limit his proposals to the field in which he is now specially working. His idea seems to be that every Ceylon planter should sell his tea to the vast organization he proposes, with himself as its head; that no one outside of that organization should, in fact, be able to procure Ceylon tea for the supply of markets yet established or to be established all the world over. This, as it seems to us, is a thoroughly Yankee notion. But it is very certain that any attempt made to give it effect, to restrict our planters from selling in the dearest market open to them, would utterly and entirely fail, although some measure of success might possibly have attended it if it had been made in the days when tea planting in Ceylon was a young industry and channels for disposal of its produce had not been opened out. It is no wonder that a reference made to a gentleman specially fitted by his local experience both here and at home to give an opinion on the scheme should have resulted in his emphatically declaring it to be "Moonshine!" A very few minutes of conference with Mr. Mitchell and his colleagues of Messrs. Darley, Butler & Co. will, we feel assured, have convinced Mr. May of the impracticability of any such idea as he has broached. It is only wonderful that he should ever have entertained it, after having conversed with Mr. Grinlinton during his recent visit to the States. Mr. May will certainly return to New York, after his present visit to London a "wiser," though we hope not a "sadder" man. But if mortification should be the result, he must lay the blame on his own "o'er-vaulting ambition."

an American Ceylon Tea "corner" on a large scale. What his reception has been I can gather pretty well from the opinions those interviewed have expressed to me in conversation on the subject. Judging of it in the form in which he has submitted his project, they do not hesitate to say that it is unworkable and undesirable. The result of an interview with him is a rather favourable impression of his personality. He is quite young and somewhat of the "masher" in his get up, and cockneyish in his speech. In America only the best of everything was tolerated, and that was why China tea was taking a back-seat and Ceylon leaf coming to the front. Quality made all the running in their great country, and that was the reason why they wished to place the article in a favorable position in their market. In England cheap teas are wanted because the bulk of the public are not wealthy; but tea often the reverse, whereas in the great land of the Stars and Stripes, where marvellous developments are taking place, the great bulk of the population are well-to-do, and, being that, they can afford to buy good articles and will have none other, and that is why Ceylon tea has come into favor with them so rapidly. They numbered sixty millions of inhabitants, and they could and would buy sixty million lb. of Ceylon tea if they could get it. They have hitherto been great consumers of coffee, but the berry has risen so much in price that very many were taking to tea in preference when they could obtain it good*. His estimate, he said, had been submitted to trade experts and pronounced perfectly sound. Now his idea was that, by judicious combination, they could buy up those sixty millions of Ceylon tea, and, by having it all packed on the spot where labor is cheap, in neat, attractive, and oriental looking packets much outlay would be saved and if in addition they could procure the sanction of the Ceylon Government to stamping each packet with the official seal or arms of the authorities, by payment of a small royalty, the tea would make rapid way in public estimation with such a prestige as the stamp would give. They should not want for funds, of which they could command any amount when the arrangements for obtaining sole command of the island produce were finished; the strongest financiers would be with them, and the capital required could be had in a day. Mr. May was assured that there would be no difficulty in purchasing crops in advance on contract if the rates suited, without resort to the device of a "corner", but he did not consider that mode of making the arrangement in question would be sufficiently "comprehensive", and preferred absorbing the entire tea interest of the island—how could estate owners possibly object? Claims on their properties could be arranged for, and, though there would perhaps be some having an interest in the existing state of things by shipment to Europe and Australia, that matter could be easily arranged. There is, I think, no doubt but that Mr. Elwood May is thoroughly in earnest and a full believer in the practicability of his "corner"; but as to how many others he will succeed in bringing to his way of thinking is another matter.

—London, *Cor. local "Times."*

HOW TO SECURE AMERICANS FOR "PURE CEYLON TEA."—There are two places where, away from their own Continent, Americans most do congregate, namely Paris and Cairo or Egypt generally. The Indian Tea Association have been before us in Paris and greatly may they continue to flourish. But why should our Tea Fund Committee not take some active step to promote the free sale of pure Ceylon tea in Cairo, Alexandria and Port Said? If once it be known that the Committee want an agent for Egypt to sell only "Pure Ceylon Tea" in its towns, the right man will no doubt quickly turn up.

* This hardly agrees with the previous statement about the buying capabilities of the American people. —Ed.

DEVELOPING THE ZAMBESI REGION.

The British South African Company have engaged a practical botanist [A. Whyte, lately of Nawara Eliya.—Ed. T. A.] who has had over twenty years' experience in the cultivation of produce in Ceylon, to proceed to their territories in Zambesi and superintend the development of their vegetable resources. This gentleman in question, with whom we had an interview a few days ago, leaves early in May for Zanzibar, whence he will proceed by way of the Zambesi to his destination in the neighbourhood of the Shiré Highlands. His attentions will be directed not only to the collection and export of such native products as are likely to find a market in Europe, such as rubber, gums and gum resins, oleaginous plants, and so forth, but he will also try the acclimatisation of tropical and subtropical products. Coffee is already cultivated with success in Zambesia; tea is going to be tried, but the company are alive to the danger of over-production in this article. Cocoa and tobacco are thought to hold out greater hopes of success. As regards drugs, needless to say, cinchona will not be tried. Opium-culture has been experimented in before in Mozambique, the result being a signal failure. Cardamoms and vanilla are among the first drugs to be tried, and the authorities have promised to lend every possible assistance in procuring plants and giving advice as to cultivation. Now that a trained botanist is about to proceed to the country of the strophantius, we may expect the speedy elucidation of the mystery still surrounding the botanical classification of the drug. The first season or two, however, are likely to be taken up with preliminary investigations of the climatic conditions of the country, meteorological observations, &c. Native labour will be employed in the first instance, under the supervision of overseers from Zanzibar, Ceylon, and British India.—*Chemist and Druggist.*

MICA IN SOUTH AUSTRALIA.

An experienced prospector sent out by a number of gentlemen in Adelaide last December has discovered a large deposit of mica of superior quality amongst the ranges about sixty miles from Parioa. The place is called by the blacks 'Mito Miltana,' meaning 'big mica, or great lot of mica'. It is on a steep mountain creek, which is so plentifully strewn with large pieces of mica that a person is continually expecting to come upon the source of the supply, but he has to travel about a mile and a half before the creek cuts sharply through a dyke of fully 150 ft. wide, and exposed on either side to a height of 200 ft. The rock in which it occurs is a compact felspar with veins of quartz and mica throughout it. He reports that there can be no question about the abundance of the mica. The rock is solid, and requires a few shots in it before large pieces can be got, but with proper means he thinks he can send down a large quantity of very fine pieces. He has found a good road for drays into the mica over a saddle in the range, and he says that drays can be taken within fifty yards of the place. The cost of carting to the railway would not exceed £1 per ton.

The Government geologist also reports that several prospecting parties are looking for or obtaining mica in the district of the Alice Springs. The mica is generally found in coarse granite dykes associated with quartz reefs or blows, scattered through the rocks, and also in benches and layers. It is uncertain in its occurrence, and the small surface outcrops are easily worked. When these have been worked out, shafts will have to be sunk in the granite and gneissic rock, and the benches and irregular layers of mica sought for by drivers and crosscuts. The mica outcrops are tolerably numerous, but it is only in exceptional cases that the plates are of a size considered worth working.

TECHNICAL AGRICULTURAL EDUCATION IN FRANCE AN EXAMPLE TO CEYLON.

At a meeting at Fakenham, at which Sir Willoughby Jones presided, Mr. Buckmaster referred to the recent efforts of the French Government for the technical education of small farmers. At the annual agricultural show at Chartres, the children, both boys and girls, exhibited a large number of copy-books, which contained descriptions of the best methods of budding and grafting trees, specimens of the various kinds of wheat and other grain grown in the district, specimens of the insects injurious or otherwise, the different grasses and weeds—all illustrated by simple but fairly executed drawings. The children varied in age from ten to thirteen. Now we have nothing like this in English rural schools of much higher pretensions, and with lads of greater age. In the Department of the Haute Marine an agricultural text-book is daily used in all the rural schools, boys are taught to distinguish between the useful and useless, and prizes are given. Mr. Buckmaster concluded as follows:—“I see industrial schools in all parts of the country, where lads are daily at work on the land. Cannot something be done with these schools? Is there nothing to learn on the land except digging, and hoeing, and planting? Would not the teaching of these French schools make lads more intelligent, better able to think and to reason, better colonists and better citizens?—*Daily News*.”

PADDY AND DRY GRAIN CROPS IN CEYLON.

SEASON REPORTS.

From the abstract of season reports for April 1891 published in the latest *Gazette* we learn that in the Colombo district the condition of the paddy and grain crops was good generally. In some villages of Hewagam Korale the mutton harvest is being reaped and in some parts of Siyane Korale East preparation for the maha cultivation is being made. There is no distress or want of food anywhere, and the health of the district is good. In Kalutara sowing for yala is reported to be nearly finished. There was the usual extent sown but very little dry grain cultivation. In Negombo the fields were being ploughed and sown, there being a fair extent in both korales. Coming now to the Central Province and dealing with the Kandy District it is reported that in Yatinuwara the prospects generally of yala are good and that in Tumpane where the maha harvest has been closed the crop of paddy and dry grain is less than in previous years by a half. In Pata Hewaheta the paddy harvest is also closed. A fair crop has been reaped from irrigated lands but bad from land dependent on rain, some fields have been wholly abandoned. In Uda Dumbara where the maha harvest is in progress the crop of paddy is reported fair and of dry grain middling. In Udapalata yala has been sown with success. In Matale the hill paddy is being reaped and is very poor in Matale North. Of the three districts comprising Nuwara Eliya, Walapane is the only one where there is dry grain and owing to the drought the crop which is being reaped is very indifferent. Here paddy is in ear and the prospects are fair. There are also fair prospects for the crop in Uda Hewaheta and a good paddy crop is being reaped in Kotmale. The Northern Province comes next and opposite Jaffna there are the following remarks:—“Threshing of paddy going on in Karachi division. Rain general on the 7th, 16th, and 25th April. Dry grain crop of the second quarter being gathered in. The grains usually cultivated this quarter are sown in paddy fields mainly dependent on rain, very few of the fields being irrigated from wells.

Though the rain proved beneficial, it was not sufficient. Tobacco—a good crop being cut throughout all the district.” In Mannar the Kalapokam paddy crops are all reaped. Sowing for Sirupokam has not begun and there is no dry grain. From Vavuniya it is reported that the paddy and dry grain crops have been reaped the former being “bad” and the latter “poor,” due in both cases to drought. There is also this remark:—“Last year’s chonas sown with gingelly; too early yet to judge of probable crop, scarcity of food anticipated shortly and relief works under consideration. From Mullaitivu the report under the heading of dry grain is “fair,” and under paddy “Kalapokam crop reaped; good in maritime patus, bad in Tunubkai and Karunavel patus, fair elsewhere.” In Galle the condition of both crops is good, in Matara the prospects for the whole are favourable, although in one or two places complaint is made of drought. In Udakiriwila some damage has been caused by floods and loss of dams. From the Batticaloa district of the Eastern Province it is reported “Early munnari excellent. Crop of Batticaloa north on about 16,500 acres harvested. Later munnari crop of Batticaloa south on about 7,500 acres is being cut; alleged damage by blight. Early pinmari of Batticaloa south on about 1,000 acres is in ear; later pinmari cultivation is in progress—about 15,000 acres. Tank water not much used as yet owing to river supply being plentiful still. Other grains and vegetables are reported last year (*Sic*).” Regarding the condition of paddy in Trincomalee the following report is made:—“Munnari crop good in the gravets. Tampalakam and Katukulampattu harvests nearly over. In Kottiar, ready for harvest, except at Malliakative, where somewhat damaged by insects. Pinmari cultivation delayed by murrain.” In the North-Western Province the prospects are fair but some damage has been done by rain. From Nuwara Kalawiya in the Anuradhapura district of the North-Central Province it is reported: “Rainfall deficient and partial. Some tanks have one-half and one-third filled, others close by have barely drinking water. Rainfall due to local thunderstorms and not general. Rivers here and in North Matale dry. A small maha harvest expected. The showers are beneficial to the growing tala and mandiri chenas. Prospects of yala crop unfavourable. Rice very scarce in villages. Kurakkan sufficient for present needs.” In Tamankaduwa the rainfall is reported to have been only middling. The general condition of the crops is fair. In the Badulla district of the province of Uva the dry grain is reported as middling in Bintenne, and the paddy in the same condition in Wellawaya. In Udakinda the paddy crop is improving owing to recent rains, but in Bintenne it has been affected by drought. In Buttala Wiyaluwa poor crops are anticipated owing to the many appearance of worms in many fields. In the Ratnapora District of the Province of Sabaragamuwa the “Operations for sowing yala harvest throughout district much favoured by recent rains, but results of murrain seriously reduce extent cultivated in Meda and Kolonna Korales. Chenas cleared for el-wi and fine grain during month; not burnt off yet.” From Kegalla it is reported “Four Korales fields ready for yala sowing. Weather favourable. Chenas being cleared for hill paddy. Kurakkan about to be sown in Four Korales. Rain plentiful. Clearings going on for hill paddy. No cattle murrain. Outlook good.”

On May 24th a *Government Gazette* Extraordinary was issued containing a return of the grain crop prospects for the first quarter of 1891. In the Colombo district of the Western Province the prospects of

the crops are stated to be fair; and in Negombo "crops damaged owing to want of rain in Sept. 1890;" and in Kalutara rain is desirable during the third and fourth weeks of the second quarter. In the Central Province it is reported from Kandy that the want of rain is much felt, and the same complaint comes from Matale South. In other districts the crops have been affected not only by the want of timely rain but by insects. Coming now to the Northern Province the remarks opposite Jaffna are—"Prospects generally good, the unusual rains in February and March having benefited the standing crops and the pasture for cattle." Regarding Vavuniya it is said: "In a month or two food will be scarce. Very little seed paddy in the district for this year's cultivation. From Mannar the report is the rainfall in the previous quarter was deficient, particularly in December, and the tanks did not fill. Very few remarks are made regarding any of the districts in the Southern Province, but regarding the Batticaloa district of the Eastern Province the observations are of a lengthy character. The following general remarks however is perhaps all that is necessary to give:—"With such favourable seasons, there is every prospect of a prosperous year. Trade is reviving, credit restored, and money available for fresh investment, as evidenced by my having already received application for several hundred acres of land for coconuts and paddy. Nor is this surprising, considering that a good year, such as the present promises to be, throws probably an additional £800,000 into the district." From Trincomalee it is reported that the water supply is good except at Kantali where it is not quite sufficient. In the North-Western Province it is reported from Kurunegala. "Weather at present favourable for yala cultivation, but the rain was too late to do any good to the maha crops." In other districts the supply of seed paddy is said to be short. In Puttalam a failure of the paddy and kurakkan crops was feared but they were saved by a heavy fall of rain towards end of Jan. In Chilaw the prospects are fairly good. The reports from the Province of Uva vary a good deal, some districts suffering from drought, while others have had plenty of rain. In the Province of Sabaragamuwa the harvest seems to have been on the whole good. From the North-Central Province the report is that Chena is sufficient for present needs, but that there is very little rice available at paddy is held up for seed for Yala sowing if the usual rain falls.

VALENTYN'S HISTORY OF COFFEE.

(Continued from page 874, Vol. X.)

PART III.

M. Paschius who maintained that Coffee was known in the time of King David—Parallel passages from Scripture—The Author's own opinion about it—Du Four's Book on Coffee—The Persians believe Coffee to be a species of Mulberry—The opinions pro and con of divers Philosophers, Apothecaries and Physicians as to the effects of Coffee drinking—Nicolas de Blegny's Treatise on Coffee, Tea and Chocolate which appeared in 1687—Mr. Anthony Galland's Book on Coffee—Abulcader Mohamed and Abdul Gaffar the earliest writers on the subject—One Mohamed Ibn Saib of Dhabban in Arabia Felix goes over to Persia in 1163, and finds some of his brethren there in the habit of drinking Coffee; on his way back, feeling sick, he thinks of it takes a good strong draught and finds it very efficacious in raising his drooping spirits—How the people of Mecca prepared Coffee from the husk, and how they played Chess and Tjouka and kept attention awake by taking sundry sips of the beverage

—The use of Coffee prohibited in Egypt by the Sultan Kair Beg, and, in Mecca, by its Governor, who, despite the arguments of the leared, believed that Coffee like Wine was intoxicating—The Governor summons an assembly of Divines who state their opinion—The matter is then referred to two eminent Persian Physicians of Mecca, brothers, who are both opposed to the use of Coffee—Oze Benjazlah, however, comes out strong in favor of the beverage and is backed by a powerful majority; but the Persians insist that Benjazlah knows nothing about it—All concur however that Coffee has the effect of disordering the "Organs of the Brain," the Mufi of Mecca alone dissenting; and the use of Coffee is accordingly prohibited and put down by the strong Arm of the Law—Coffee Bibbers of Mecca persist nevertheless in sipping the beverage by stealth, at the risk of losing their necks, and of being paraded thro' the Town on the back of a Jack-Ass—The Sultan of Egypt takes a nubrage at certain assinine proceedings of his Deputy at Mecca and orders him forthwith to rescind the obnoxious decree—The Deputy obeys and rescinds it accordingly—The Persian brothers, thus discomfited, betake themselves to Cairo, where they amuse themselves by lampooning the Grand Signeur Selim, and lose their necks in the bargain.

"A certain gentleman M. Paschius by name maintains in his Latin Work published at Leipsic in A. D. 1700, that the parched corn spoken of in 1st Samuel xxv. 18, which Abigail, amongst her other gifts, presented to David to appease and avert his wrath, was no other than Coffee beans.

Of such parched meal &c. we read in God's Holy Word more than once, as in Lev. vi. 21, vii. 12, and 1st Chron. xxiii. 29; but I cannot admit however, that by that gift of Abigail we can understand anything else than what the word implies, to wit, parched corn more especially as I find in 2nd Samuel xvii. 28, the distinction clearly drawn; for, amongst the presents of Berzillai and other friends of David, mention is made of roasted wheat, barley, and meal, and of parched beans and lentiles; and hence I opine that they were all parched or roasted, not excepting the meal and the wheat, and the passage in question before cannot be understood as having any other Coffee beans in particular.

Hence it is clear on the one hand with reference to these nice distinctions, that the parched corn and parched beans in Abigail's gifts, cannot be understood to mean Coffee beans; but on the other hand however it appears quite evident from the same passage 2nd Sam. xvii. 28, that the ancients were wont to go in quest of a certain species of beans and lentiles (the same distinction being observed between beans and lentiles. Ever since I became acquainted with Coffee I was inclined to believe that the beans referred to in this verse could be none other than Coffee beans, or at least some sort of beans used in a similar manner as the Coffee. I was not, however, led to this belief by the strong opinions expressed by M. Paschius or any other person; but this idea occurred to me whilst I was occupied in translating the Bible into the Malay language about the year 1690, and it was not till after a careful consideration of the verse referred to that the idea forced itself upon me, (*oppeborreid*, literally, bubbled up, I have since adhered to this opinion. There are others again who went still farther and insisted that the red portage, which Esau longed for Geo. xxv. 30., was nothing more or less than liquid Coffee, though this does not seem to me quite as probable as the foregoing supposition.

But to return to Du Four, who asserts that Coffee was not known in France till after 1645, and that when he wrote his Book, only 25 years had elapsed since Coffee began to be used there; that even it's proper name was not known then, and that when it was first used in Paris, it was believed to be a species of the mulberry.

At a later period when Coffee became more widely known, the Philosophers, Apothecaries, and Physicians were not unanimous in their opinion respecting it's quality or it's effects. Some rejected it altogether as a Caput Mortuum, and hence as prejudicial to health.

Others again, more grave and less choleric, were of opinion, that Coffee even after it had undergone the process of roasting still retained many of its oily and wholesome properties, and that tho' it might not tend to improve the health of persons of a delicate frame, it was very beneficial to persons of a sound and vigorous constitution who used the same moderately and did not overload their stomachs with too copious draughts, nor with too strong infusions. Coffees like medicine however healing in it's effects might, otherwise, prove injurious to health if used immoderately.

In 1687, a small Book appeared which professed to treat of Coffee, Tea, and Chocolate, by Nicholas de Blegny, but it consisted in the main of extracts from Du Four's Pamphlet.

Mr. Anthony Galland who was also a Traveller in the Levant and well skilled in the oriental languages wrote likewise a treatise on the origin and progress of Coffee.

He obtained all his information from a manuscript in the King's Library and afterwards sold his Book in Paris in 1699. The writer of that manuscript was one Abdulsader Mollamed, whose ancestors were natives of Media. He was born in Mesopotamia and was of the sect or persuasion of Henbeli well known amongst the Moors. The Title of this Book was "What believes one most to consider and believe concerning the true nature and efficacy of Coffee." That is "Whether it was lawful for the Mohammedans to use it."

This little work which consisted of seven chapters dwelt on the Etymology of the word *Caweh*, the virtue of Coffee, and the land where that beverage was first used.

It was written in Egypt, Anno Hegira 996 or in the year of the flight of Mahomed from Mecca which according to the reckoning of some (tho' there exists a great difference in the calculations) would answer perhaps to the year of Our Lord 1578.* It seems after all, the Abdulsader Mohamed himself borrowed the subject from the writings of one Szeieh Abdellion Ibu Abdul Gaffar, who wrote on the subject long before him.

But in order to point out the exact time when a right knowledge of Coffee drinking was established, it is necessary to seek for information from a remote period.

Dzamaleddeen Aboe Abdallah Mohamed Ibn Saib, of Dhabban, a town in Arabia Felix, then Mufii of Aden, repaired about the middle of the year 1468 to Persia and during his sojourn there, found some of his countrymen take Coffee; but he paid no particular attention to the circumstance at the time; on his return however homewards to Aden, finding himself in a very weak state, he thought of the Coffee which he saw used by his countrymen and tried some in the hope that it might do him some good and experienced the relief that he sought. He further discovered many other qualities in the Coffee, viz, that it was efficacious in removing head aches, enlivening the spirit, and keeping off drowsiness. These stimulating qualities induced him and a D-rvised to partake of the beverage when they went to prayers at night.

He likewise partook of it during the performance of many other of his devotional exercises, and since that time this drink became more general in Aden amongst all people of consequence, partly upon the recommendation of Dzamaleddeen himself and partly upon that of Mohamed of Hadramaut a town in Arabia Felix.

Prior to this period, Coffee was not known in Arabia where this bean grows, or elsewhere in the East, but a corollary to this Arabian writer, Coffee was long before this in use in Abyssinia, although Messrs. Jobus Ludolf, Piero Telles, and many others who had written accounts of Ethiopia made no mention thereof.

From Aden this beverage was introduced into Mecca in 1500 where it was not then prepared from the beans, but from the shells (husks) which were brought from Yemen; for Mecca lies not (as many suppose) properly in Arabia Felix, but in the Government and deputyship of a stony region of Arabia which some call Tahamah and others Hadzazr and which is situated on it's border.

The use of Coffee now became more general and almost every body partook of it, as he whiled away his time in a game of chess, *tzooka*, the game of beans or some other amusement of the kind.

From Mecca it passed to the other towns of Arabia, and thence to Egypt especially to Grand Cairo; all which took place not long after 1511. But shortly after this the use of Coffee (which was introduced somewhat later from Cairo into Turkey) was prohibited in Egypt by the Sultan Khair Beg. The Governor of Mecca also who held office under the Prince of the Circassian Mamelukes, then Masters of Egypt, prohibited it's use there, imagining it was wine, for he found some people partook of this liquor in the Temple to keep themselves awake during the recitation of their orations. In spite, however, of the explanation given him of the harmful qualities of Coffee, he was obstinate, and being, at the time, quite ignorant of the innocuous qualities of the beverage which he supposed like wine had an intoxicating effect (and the use of wine was forbidden by their Law) he instantly ordered the offenders to quit the Temple and warned them against a recurrence of similar conduct.

On the following day he summoned an assembly of divines and related to them what had occurred. They were all unanimously of opinion that Coffee drinking was opposed to the Mohammedan Law and consequently that it ought to be suppressed.

They carried this matter, however, to far greater lengths here. An investigation was to take place in order to ascertain whether or not Coffee was detrimental to the *body* as well as the *spirit*; and it was accordingly judged expedient to refer the matter to the Faculty and take their opinion upon the point.

Here upon the Governor sent for two Persian brothers, the principal Physicians of Mecca, who had but a superficial knowledge, of the art and one of whom had already written something disparagingly of Coffee, and submitted the case to them for opinion. They said that the Coffee husks being in their nature very cold and dry were detrimental and injurious to health; but a Physician of Bagdad named Beuzazlah, who was one of the assembly, observed that Coffee promotes the digestion of the phlegm, and that according to his opinion it was hot and dry (contrary to the opinion of the two others.) The rest concurred with him, and the opinion that it was not injurious prevailed.

The Persians then said, that Beuzazlah was mistaken, and that they spoke of another plant altogether, which he mistook for Coffee.

Finally, they came to the conclusion, that be the effects of the Coffee good or bad, it would be the safest plan for a Mohammedan to abstain from the use of it, especially as there were some amongst them, who placed Coffee amongst the things which disordered and confused the brain. (*Te meer, alsoer zonnige waren, die de Coff onder de dingen stelden, die de hersenen bedroeven.*)

The Mufti of Mecca alone, a great Jurist and Divine, ventured to argue with some vehemence in favor of Coffee, despite the Governor and the whole assembly; but his opinion and arguments were rejected and laid aside by the Zealots of their Law, and the use of and all dealings in Coffee were prohibited under severe punishment. Injunctions were given to the Chief Magistrates to watch against all infractions of the order, and all the Coffee found in Mecca was directed to be burnt and destroyed, not excepting the Coffee in the Warehouses, the property of the Merchants. But these rigorous and severe measures did not either prevent or restrain those who were already strongly addicted to Coffee, from continuing the use of it stealthily in their houses, under a consciousness, that the prohibition was the result of an ill-judged sentence of the assembly, especially knowing, as they did, that the Mufti himself was so strenuous an advocate for it.

In the mean time an unfortunate delinquent fell into the hands of the Magistrate. The offender after being severely punished was as a warning to others, mounted upon an Ass, and paraded through all the streets of Mecca (*op een Ezel sittende, door alle de straten van Mekka wierd geleid.*) But this state of things did not continue long, for the Sultan of Egypt

* A. D. 622. Era of the Hagra or flight of Mahomet from Mecca to Medina. Tytler's Table of Chronology.

far from approving the indiscreet zeal on the part of his Governor, was much surprised to find so severe a punishment inflicted on Coffee drinkers, inasmuch as in Cairo, where there were so many abler Physicians than at Mecca, the opinion was in favour of Coffee drinking, and besides none of the teachers of the Mohammedan Law there considered Coffee drinking as opposed to the doctrines inculcated in the Koran. For these reasons, he ordered his Governor to recall and rescind the Decree, which he was obliged to do, tho' much against his will.

The two Persian Physicians finding themselves much despised and looked down upon, since the recall of the Decree, left Mecca for Cairo, and were there put to death for the imprecations hurled by them at the head of the Grand Seigneur Selim 1st, who came to wrest Egypt from Campsoni al Gauri, and who was the last Sultan who restored the practice of Coffee drinking in Mecca."

PART IV.

The good people of Mecca sip Coffee *ad libitum* until a certain Oadi shuts up all the Coffee shops; but his successor, a better man, gets them all opened again—Soliman the Great sends forth an Edict denouncing the use of Coffee in Mecca, and it is generally believed that his Sultana is at the "bottom of the dodge"—The Pacha of Egypt who is rather fond of Coffee confers with his wise men on the subject and comes to the conclusion that the Great Soliman is a "fool and a knave"—Mr. Anthony Galland again; and some choice verses on the virtues of Coffee by a Turkish Bard—Constantinople—How Sjenis and Hekem flourished there and how their Coffee houses happened to be always choke-full of Poets, Philosophers and Chess players—The Mosques begin to be neglected the Turkish Divines sound the "Tocsin of alarm," and the Multi or Pope thinks it high time to shut up the Coffee shops, and they are shut up accordingly—The Turks get to be excessively fond of the beverage and won't give it up for "love or money"—Of a Vizier who attempted to suppress the free expression of public opinion and of his two sons who played the part of eaves-droppers and brought certain innocent people into scrape—And lastly of certain honest shop-keepers who took advantage of the Coffee drinking mania and sold their good at a high premium.

"After the conquest—of Egypt by Selim (which took place in 1516.) it appears that Coffee drinking was more properly understood in Turkey, and by degrees the use of it became known throughout the country, especially as the use of Coffee was re-established and restored in Mecca, and no further questions were raised there up to the year 1525. The Oadi or Judge of the town, however, caused all the Coffee-houses to be closed up that very same year owing to the great irregularities which took place daily, but without preventing, in particular, any person using the drink in his own house. His successor however, ordered the re-opening of (the Coffee-house, forbidding only the recurrence of similar irregularities and disturbances.

From Cairo the use of the Coffee spread gradually, 'ere it was known in Turkey, first to Damascus, and then to Aleppo, and eventually to Constantinople.

Subsequently in 1541, a caravan from Damascus reached Mecca with an Edict from Soliman the Great denouncing the use of Coffee, but this order was not strictly observed, as it was generally known that it emanated from the Turkish Sultana, in her overwhelming solicitude for the Emperor, who indulged in the drink. Whilst at the same time the Bashaw of Egypt took the opinion of all the Teachers of their Law in writing, shewing the vanity of such an order, and the ignorance of those who condemn this drink.

Howbeit there prevailed some years afterwards a great diversity of opinion in respect of the use of Coffee at Mecca; the people of that town being divided into two parties each maintaining a different opinion,

Thus far proceeds the account of the aforesaid Arabian whose manuscript Mr. Galland have availed himself of as also that of a Turkish writer named Pitsjevelli (after Pitsjeri a town in Hungary) one of the three

Treasurers of the Turkish Empire. Mr. Galland also obtained some information from a Poem written by Belligi, a Turkish Poet, which agrees, in substance, with the foregoing account, and of which I subjoin a poetical translation:

Tot Halep vind m', en tot Damascus by de Grooten
En ook tot Cairo (daar m' al mede wret ic ontblooten
De Coffi—Boon van hare schil) de Coffi—vrugt
Die lieve en diere drank, die wel zoo'n diepe zuet
Uit menig angstig hart na hoven wist to haalen,
Eer die by 't Turks Beleid begon to Zogepraalen.
* * * * *

[The following, it must be confessed, is rather a free rendering of the Dutch version of this short Turkish Poem, from which a few lines have been given above. Your readers will, of course, excuse the shortcomings of the Translator in his attempt to give, at least, the spirit of the original in English verse.]

I sing the Coffee Plant, which, tho' oppos'd by Fate
Has spread thro' ev'ry Country, City, Sia'c,
At Halep, Cairo and Damascus too
It has secur'd the fame which was its due.
Say, who could estimate
The virtues of that drink
Which made not one,
But many thousands think,
And write such works as made the vulgar stare
And fill'd the world with disputations rare!!
Say, who could well describe its wondrous pow'r
To cheer the heart in "sorrow's lonely hour"
Sustain the drooping spirits of the fair
Who cag'd in Harems, pine in sadness there;
(Unhappy birds, I wish I had the key
To open wide your doors and bid you all be free
Coffee! rare plant!
Where'er thou deign'st to grow,
The source of wealth
To hundreds here below:
Some thought that thou did'st *once*
The place of wine supply,
As well as Beer
As some will scarce deny.
Where'er thou art, fair plant,
Of whatsoever clime,
Thy virtues gr-at have puzzl'd oft
The wits of olden time;
But now we know thee well, fair plant,
And all thy virtues too:—
My task is o'er, farewell my muse
Ye Coffee, plants adieu!!!

Prior to the year 1554 very little was known of Coffee at Constantinople and still less of Coffee houses. It was the Sultana who did her best to put a stop to Coffee drinking at Mecca, but in the same year nearly a century after Coffee had begun to be first used in Aden, and in the reign of Soliman the Great, two individuals named Sjenis and Hekem, the former of Damascus, and the latter of Aleppo established Coffee houses in Constantinople in a certain quarter called Tahita-Oalah, and sold the liquid to people of learning, Poets, Chess Players (more properly Szah-Players or lovers of the King's Game, for Szah signifies a King in the Persian language) or others who were inclined to amuse themselves with some such games.

These houses were afterwards greatly multiplied and the very Turkish Courtiers resorted to them to regale themselves with a cup of *Cawah*.

As the use of Coffee became now more general and extended, these gentry were often to be found in the Coffee shops than at their Mosques. This gave rise to no small stir and grumbling amongst the Turkish Divines, who loudly declaimed the practice as repugnant to the tenets of their Law, and got the Multi on their side, who gave his assent to the shops being closed.

Hereupon, all the Coffee houses were immediately shut up, and instructions conveyed to the Chief Magistrates to see this order strictly enforced. Stern and absolute as this order was, it had not the effect of altogether putting an end to the use of Coffee.

Under Amureth the III. this order was again revived, but the abandonment of so agreeable a beverage was not to be endured by the Turks, who, by bribes and the connivance of those whose duty it was to watch over it, still carried on the practice of Coffee drinking, though not so publicly as before, the order being entirely disregarded,

This order was still less regarded during the time of the succeeding Mufti or Turkish Pope) who was not as solicitous about it as his predecessors. He set aside this order, and not only permitted a free and undisputed use of Coffee, but he himself and the rest of the fraternity indulged in it and their example was immediately followed by the countries, &c.

It is also worthy of remark that these Coffee houses brought great gain to the Prime Minister or Chief Vizier, who got from each house from one to two ucats daily, besides the one Asdar* hitherto levied on every cup of Coffee.

Mr. Galland further narrates that since the war of Candia when State affairs were discussed with some freedom of speech in these Coffee-houses by those who frequented them, the same were directed to be closed by the Grant Vizier Kosproeli or Kioeperli, who with his two sons, who acted the part of vigilant informers, spread no pains in visiting these houses *incognito*, and listening to all slanderous discourses against the Government, in order to punish the delinquents with great rigour—and the same vizier during the minority of Mohammed the 4th caused all these houses to be closed up, regardless of the great loss which this proceeding entailed upon himself.

Although the Coffee houses were suppressed there was no diminution in the consumption of that beverage, for it was now carried to the public market and about the principal streets, *fresh and hot*, and sold to the public, who partook of it in the neighbouring shops, where the consumers were very welcome, as it was one of the means whereby the shopkeepers succeeded in drawing their attention to the goods exposed by them for sale, and which these Coffee quaffers were obliged, *notens volens*, to purchase."

(To be continued)

THE NUWARA ELIYA SHOW.

The promoters of the Agri-Horticultural Show at Nuwara Eliya may well be congratulated on the success which has so abundantly attended their efforts. It has been the means of creating a great social gathering when all classes, from the Queen's Representative to the native gardeners, have met together with mutual pleasure and, we may hope, with mutual advantage. Other considerations apart, were it for this object alone, such Exhibitions deserve the hearty support of everyone, and should be fostered with all possible solicitude; while the Flower Show has afforded an opportunity for floriculturists to show others the plants and flowers on which they have bestowed so much attention, and of which they may so justly feel proud. When we come to the exhibition of garden produce, we take leave of the beautiful and the showy, and enter at once upon what is useful and though, it may be, inartistic; and, though the culture of flowers is at once interesting and refining, attention to culinary produce is also profitable and conducive to the preservation of health. The addition of a horse and poultry show was, no doubt, an ingenious device to increase the attraction of the exhibition so far as the gentlemen are concerned, many of whom, we regret to observe, fail to regard a lovely flower as "a thing of beauty and a joy for ever." Although there appear to have been a number of small prizes which failed to attract competitors, the exhibition was an exceedingly pretty affair, and afforded a vast amount of pleasure to a great number of visitors from all parts of the country. Regret has been expressed in several quarters that planters prove so indifferent about the exhibition of estate produce. No doubt a varied collection of tea, coffee, cinchona, cocoa, &c., &c., would add considerably to the interest attaching to such exhibitions, but it is not altogether unreasonable to suppose that the planters of the present day are disinclined to regard *au sérieux* the flower-shows at Nuwara Eliya. Planting interest have undergone very great changes since the days

of the highly successful Shows held in Kandy and Colombo some years back. We may remark in parenthesis that Kandy is much more favorably situated for an Agricultural Show than is Nuwara Eliya, and much more likely to secure the exhibition of produce and machinery. When those Shows were held a variety of products had been introduced to take the place of the declining coffee. Cocoa and tea were comparatively new to the public; cinchona was looked upon as a great stand-by; and the different qualities of quill, chips, renewed, &c., &c., were all eagerly inspected by an interested public. But it is quite a different matter now. Tea has taken the place of coffee, and cinchona is totally disregarded; everyone knows all they care to know about cocoa, and even cardamoms and india rubber have fallen into disrepute, to say nothing of annatto, sapan, &c., &c. Moreover, it must not be forgotten that the judging of the tea samples in Kandy was attended by unpleasant differences of opinion, mainly, it is true, about what constituted a fair commercial sample, but nevertheless a feeling of irritation remained in the minds of many in spite of all efforts at explanation. When a planter found the tea he exhibited in Kandy fetching in London a penny a pound more than the gold-medal tea of the Kandy show, he naturally felt that that medal had been wrongly bestowed. Tea-making is now the business by which planters make their living, and when it comes to an exhibition in London or Melbourne, where great interests are concerned, and where the competition embraces the produce of rival tea-producing countries, we have no doubt Ceylon planters will again come forward as they have done in the past, and do their best to take the front place with their estate products. But in these petty local exhibitions it is not worth while; they lead to no business, and they require just the same care and trouble as regards the exhibits as do the more important Shows in foreign countries. In short, the flower-shows at Nuwara Eliya and Kandy are regarded as mere sources of amusement and sociability; whilst the exhibitions in other countries are meetings of commercial value and importance. Amongst the exhibits at Nuwara Eliya we notice some cinchona crown bark said to have been five times renewed. We should be very glad to know how this "fifth renewal" bark turned out on analysis, as for a long time there was an impression abroad that "renewed" bark, as well as very old "original," was apt to lose its value by deterioration: in regard to the india-rubber not thoroughly drying, but becoming hard outside, whilst the interior showed a mass of soft decaying milk, it is pretty evident that it had not been exposed to desiccation in sufficiently thin layers to enable the drying process to be thorough. The Indians in South America are said to smear the coagulating juice over a clay mould something in the shape of a soda-water bottle holding it over a fire, and, as one layer becomes dry, another is put on, until a solid lump is attained. The clay mould is then broken or cut out. On the East coast of Africa, and in Madagascar, the rubber is collected by the natives and brought to the trader in irregularly shaped lumps bigger than a man's fist. These lumps are promptly cut in two with a heavy knife—to see if any earth or stones are present—and then the rubber is weighed. We may add that the rubber has an abominable smell in this stage of preparation, and the same may be said of the rubber which comes down from the Chindwin and other parts of Upper Burmah. We have always thought that rubber cultivation was too hastily abandoned in Ceylon, but at the same time we fail to see any prospect of its being again taken up as a commercial undertaking.—Local "Times."

IMPORTANT TO PLANTERS.—An announcement of some importance to planters appears in our advertising columns today. Messrs. J. M. Kirwan & Co., Billiter Square Buildings, London, announce that the planters desirous of giving a trial to the firm's prepared paper for lining tea chests which has now been successfully tested on the London market, can have sufficient to line 25 chests free of charge on applying to Messrs. Bosanquet & Co., Colombo.

* A Turkish coin equivalent to three farthings of our money.

TECHNICAL INSTRUCTION IN NORTHERN INDIA.

We have been favoured with the perusal of a very able Minute on Technical Instruction drawn up by Sir Auckland Colvin for the guidance of his Government in the North-West Provinces of India. As there is much of interest in it to us in Ceylon we append the following summary, and call attention to the prominence given to the need of a training in mechanical industries:—

The minute is an exhaustive document comprising thirty-six heads shows what up to the present moment has been the course of matters in the North-West provinces and what has been done in Madras, Bombay and Bengal. On 16th Sept. 1885 the Government of India forwarded for consideration certain papers from the Madras Government containing a scheme for promoting technical education in industrial arts and manufactures by offering grants-in-aid to encourage the teaching in schools so aided of technical science, arts and handicrafts, and by testing that teaching by a system of public examinations. The aim of the scheme was to create and encourage technical instruction in middle-class schools. In reply to a "note" from the Secretary to the Government of India in the Home Department the Director of Public Instruction pointed out that the question of establishing Faculties of Medicine and Engineering was under consideration in Allahabad University which was also considering the preparatory course for students desiring to matriculate and the course for degrees in law and arts. The question had been brought to a practical issue of Oadh, and in Lahore it had also been considered. The question of agricultural and veterinary schools he proposed should be referred to the Department of Land Records and Agricultural as also the teaching of land surveying. Col. Forbes on the question of instruction in engineering stated that the practical instruction gained by natives at the large railway workshops at Allahabad, Lucknow, and Lahore, and at the Government workshops at Roorkee was now bearing fruit at Delhi where there were at present 17 foundries and mechanical shops, one with a 20 horse-power engine, worked entirely by natives, without European supervision; at Roorkee where there was a small foundry and shop under native management; at Meerut where there were two native foundries and shop, and at other places. He thought it unnecessary therefore for the Government in these places to start schools for technical engineering, but facilities might be given to selected middle or high schools students for going through a four or five years' course of work at a railway or Government workshop. The Director of Land and Agriculture pointed out that surveying and mensuration were largely taught in the schools under the Educational Department and that in every district in those provinces there was a school of practical surveying. He advocated the creation of a Normal School for surveying only at Cawnpore or Lucknow. Lads he so well trained in horticulture at the Saharanpur and Lucknow Gardens; and at the Cawnpore farm there were a few apprentices in training. There should be small scholarships for the maintenance of boys at the various workshops; an art school at Lucknow; agricultural and veterinary schools or classes in high schools; and drawing should be made compulsory;—Dr. Rice, Inspector-General of Civil Hospitals, disapproved of the proposal to teach up to a higher standard than that of the hospital assistant class. After a number of other details the minute goes on to state that the establishment of what has been described as "a special examination of a commercial and practical character" by the University of Allahabad is also under consideration, its aim being to give a preliminary instruction without which no large growth of technical education can be hoped for. The offer of the British India Association to establish a Jubilee School of Industry at Lucknow is also recorded, and various papers from the Bombay and Bengal Governments on the subject of technical instruction referred to, as well as lengthy

quotations made from a letter of Sir Alfred Croft and the Government's reply thereto.

Proceeding, the minute says it seemed probable that the railway, Roorkee, and other workshops provide sufficient training for the mere artisan and that his training may be left to them. What seems mostly needed at present in these Provinces is the provision of greater facilities for a somewhat higher class of training in those now mechanical industries which have been introduced by British capital into these Provinces, and in regard to which though there may be a growing demand for skilled labour, there is no indigenous supply. Facilities should be given for gaining a competent theoretical and practical knowledge of the more subordinate grades of mechanical engineering, such as is necessary to a foreman mechanic, more specially in connection with the steam engine, the railway workshops and the iron foundry; and also of the processes of cotton-spinning as employed in the mills established in these Provinces. At Roorkee there is a Government engineering college and Government workshops and it seems probable that there is the nucleus of the institution necessary. Prior to admission to such a course it will be necessary to establish some such test as to be given for the middle class, to ensure some of the knowledge of English, and as a guarantee of the good faith of those who sought for instruction. A three or four years' course of instruction, theoretical and practical, would be required, which would possibly include a term of practical training in the railway workshops and the cotton mills. The proposal which seems most practicable at present is that a certain number of scholarships should be given to be competed for by students desirous of entering the college and that the holders of the scholarships should by means of them, be able to pass through their course of instruction, whether at Roorkee or, (as part of their course) in attendance at workshops or mills. Before any decision however is arrived at, it is wished to learn the opinions of railway authorities and employers or directors of mill-bands as to whether there is a field of employment for natives trained in the kind of education proposed; that is as foremen mechanics and not mere artisans; and whether for the present the means of instruction for the ordinary artisan are sufficient; and if not what steps are possible in view of the means at Government command for improving that instruction. Assuming the class of instruction proposed is that which is most desirable it will be necessary to learn whether the railway and mill-employers are willing to allow students to go through a practical training at their establishments and if so under what conditions. It is considered premature to go fully into the question of funds until it has been ascertained that the bases on which it is proposed to build are practical.

BLACK PEARLS AND EXPERIENCE OF THE PEARL FISHERY.

We had a call on May 15th from Mr. W. de Carolis Leather merchant of Kollupitiya who had a fine black pearl to show us. It was one of the finds in the present Fishery and is valued at from R750 to R1,000. It is not a perfect one in shape, though not far out, weighs 7 carats and measures over an inch in circumference. Mr. Carolis had besides half a dozen small black pearls and two goodly lots of white ones, the proceeds altogether of his investment in oysters. We were curious to see how his experience had worked out. He had sent three of his relatives to the Fishery and they had bought altogether 64,000 oysters at a cost of some R1,800. In return they brought him one lot of ordinary pearls, some middle size, many small valued at R1,100; another lot value R200; and the black pearl, say R1,000; altogether R2,300. A poor return this considering the expenses of the party and the risk attending the sale—if the pearls should be sold—at these valuations. Mr. de Carolis intends to send the black pearl to the London market.

CEYLON PRODUCE SHIPMENTS—
ESTIMATES—AND PROBABLE TOTAL
EXPORTS IN SEASON 1891:

TEA.

In their circular of May 14th, Messrs. Forbes & Walker put the total shipments of tea from Colombo at 25 millions lb. from 1st January to 14th May of the current year. At this ratio, we should have to put down the probable total exports of the whole year at 66 millions lb., against estimates varying at the beginning of the season from 52½ millions (Mr. Rutherford's) to 58 millions (Mr. Forbes Laurie's). But it is acknowledged on all hands that, so far as it has gone, the season has been a most unusually favourable one all over the country for tea. There has been no stoppage of flushing due to drought: on the contrary the weather has been so continuously moist all through what is commonly our dry hot season, that the tea bushes have been as if in a forcing house and have kept "flushing" at a rate which set a precedent and estimate at defiance. The experience may be very different if we get a cold raw South-west monsoon with such heavy continuous rain as stops the flush, at least in the higher districts. Still, there is no reason to anticipate a worse monsoon in this respect than usual, while as for the drawback to which low districts chiefly object, namely drought, there is, we fancy, not the slightest chance of that extreme being experienced between June and December on the South-west side of the island.

On the whole then we do not see why the ratio we have adopted should not very nearly hold good for the year; for usually, the percentage of shipments has been heavier in the latter than in the first half of the year. A table in our last "Handbook and Directory" shows the percentages worked out from the experience of the seven years 1883 to 1889 inclusive, as follows:—

SHIPMENTS OF CEYLON TEA CROPS FROM COLOMBO,
GALLE AND FOR ISLAND.

For the Seven Years 1883-89, in Each Year
and Percentages.
For Colombo.

	Total for 7 years.	Average for 7 years.	Percentage on whole.
For Colombo.			
1st Quarter ...	17,820,384	2,545,764	29.39
2nd do ...	24,230,184	3,715,740	30.14
3rd do ...	2,719,954	2,954,599	23.72
4th do ...	22,451,200	3,332,800	25.5
Total, Colombo ...	87,401,872	12,145,952	100.0
For Galle ...	879,855	125,993	

This shows that we should be justified, according to the above experience, in regarding the shipments of 25 millions lb. up to 14th May as only equal to 36 per cent of the total export for 1891, which should thus aggregate 70 millions lb! In anticipating a total in excess of 60 and not far short of 65—say 63—millions lb., we are therefore apparently well on the safe side, unless the present low prices check shipments.

If we go by the Chamber's latest return and compare the shipments for four seasons up to its latest date with the totals for the years, the result works out as follows:—

Years.	Total Shipments.	Shipments to 14th May.	Per cent. &c.
1891 (est)	63,000,000	24,105,743	38.26
1890 ...	46,901,554	15,038,189	32.06
1889 ...	34,048,085	11,603,616	34.07
1888 ...	24,381,796	6,005,512	24.60

This shows how much less is the percentage (61.74) that we leave for the shipments of the rest of this year, than was required in the three previous years.

We may now show the wonderful way in which the Ceylon tea crops have run up beginning with 1885, and giving the percentage of increase for each year. Of course it will be borne in mind how much less important is a large percentage on a small export, than one on the large shipments of recent years:—

	lb.	Annual increase.	Percentage of annual increase.
1885 ..	4,411,578		—
1886 ..	8,111,137	3,699,559	84
1887 ..	13,800,545	5,689,408	70
1888 ..	24,381,296	10,580,751	75
1889 ..	34,048,085	9,666,789	40
1890 ..	46,901,554	12,853,469	37
1891 ..	63,000,000	16,098,446	34

(To be continued.)

BARK AND DRUG REPORT.

(From the Chemist and Druggist.)

London, April 23rd.

CINCHONA.—The public sales which took place here on Tuesday were rather heavier than the preceding auctions, the catalogue consisting of:—

	Packages	Packages	of which 1,122 were sold
Ceylon bark 1,144	do	1,799
East Indian bark	1,709	do	1,709
South American bark 172	do	150

Total 3,025 do 2,981 do
A fairly steady tone prevailed, and nearly the whole of the supply offered sold at rates which are said to show some slight improvement on the last auctions, although they cannot be said to be notably higher. The average unit may be put at about 1d per lb. The assortment of barks offered was very poor, and again the East Indian cinchona largely outnumbered those from Ceylon.

The following are the approximate quantities purchased by the principal buyers:—

	Lbs.
Agents for the French manufacturers	... 136,914
Agents for the Brunswick work	... 130,915
Agents for the American and Italian works	... 98,111
Agents for the Auerbach works	... 89,489
Agents for the Frankfurt O/M and Stuttgart works	... 63,678
Agents for the Mannheim and Amsterdam works	... 63,602
Messrs. Howards & Sons works	... 55,358
Sundry druggists works	... 35,012

Total quantity sold	... 653,179
Bought in or withdrawn 9,390

Total quantity offered ... 62,578

QUININE.—The market is just a shade better this week, sales being reported of 5,000 oz. "Auerbach" brand at 10½d, and about 5,000 oz. B & S or Brunswick, all in second hands, at 10½d per oz. It is said that there are no further sellers under 10½d per oz.

TEA IN INDIA.

(From Watson, Sibthorp & Co.'s Report.)

1, HARE STREET CALCUTTA, May 6th, 1891.

They have now the pleasure to give you the figures showing the actual output of the Indian tea crop of 1890.

Actual output of crop of 1890. 105,836,106

The total shipments to all places from the 1st May 1890 to 31st March 1891 having been 104,954,625 lb., the difference represents the local consumption and any small portion of last season's crop still to go forward. It will be seen from the above figures that the actual output was less than the original estimate by more than 9 million lb.

The following figures kindly furnished to the General Committee show the estimate of the crop of 1891:—

Original Estimate of crop of 1891 119,795,111

being 4½ million lb. over the original estimate of the crop of 1890. Taking the shipments to other places at 10 per cent over those of last year and making allowance for local consumption, there will remain about 112 million lb. for export to Great Britain against 98½ million lb. shipped there during the past season. It is possible, however, that the actual output of the crop of 1891 may be considerably less than the estimate as was the case last season.

TOTAL EXPORTS OF TEA FROM CALCUTTA, FROM
1ST MAY 1890 TO END APRIL 1891.

	1890-91.	1889-90.
Great Britain...	98,132,298	98,303,110
Australia and New Zealand	4,837,393	3,596,041
America	134,818	187,500
Bombay	901,297	1,133,874
Sundry Ports...	307,123	419,503
	104,313,834	103,640,142

FLOODING THE PRODUCE MARKETS.

The following editorial from the *Chemist and Druggist* (April 18th) contains a grave lesson to Ceylon planters, who, indeed, know too well already from their experience of cinchona bark, what over-production and ruinously low prices mean. The question is now whether there should be any further extension of tea cultivated here, seeing the heavy production and the scarcity of labour which are likely to be encountered :—

Not the least interesting among the results of the immense expansion which the boundaries of our empire have undergone in Africa and Asia during the last five years, and of the extraordinary revival of the feelings of kinship among the scattered parts of the Empire are the numerous schemes to render the outlying portions of Greater Britain more productive and to utilize their latent resources to a greater extent than heretofore. To say that, from climatic and economic standpoints, there is scarcely a natural product which cannot be produced within the limits of the British dominions is a truism so trite that we almost apologise for repeating it, and general sympathy with all efforts to increase the productivity of any part of the Empire and enhance the well-being of its inhabitants, may be similarly assumed. But enthusiasm for Colonial development has its dangerous side. And to no one should the reverse of the medal be more apparent than to the produce merchant, who with an intelligent interest keeps himself informed of the new sources of production of the raw materials of industry, and compares their probable supply with the demand which may fairly be expected for them. The drug importer in particular enjoys unusual means of observation on this point. No other merchant draws his raw materials from so many sources, and there is probably no other trade in which the grades of usefulness of any given article, from the almost absolutely valueless to the highest excellence, are liable to vary so much as in his.

To the produce importer, who sees the probability and often actually experiences the difficulties attending the glut of his market by the introduction of new developments of enterprise, the proverbial benefactor who enriches the world with that often-mentioned additional blade of grass, is not always so welcome as he expects to be. The authorities of the Royal Gardens at Kew, who are doing eminently useful experimental work in connection with the acclimatisation of produce, are not free from the risk of allowing their zeal to outrun their discretion, from the importer's point of view. It may be suggested even to them that in selecting their new investigations they might at least first ascertain approximately the world's requirements and capabilities of absorption. A case in point has occurred this week. Before the Royal Colonial Institute, on Tuesday night, Mr. Morris, the energetic assistant-director of Kew Gardens, read an interesting paper on the "Leeward Islands"—that little group of western paradises outwining the Caribbean Sea with a garle of fragrant verdure. Mr. Morris has previously spent many years in botanical pursuits in the Antilles, and has just returned home, filled with re-awakened memories of the unexhausted fertility of the Antilles. He talks of their wonderful productiveness, and urges the investment of a "moderate amount" of capital in their development. Dominica produces annually about 8,000L. worth of lime-juice; and in Montserrat a thousand acres are covered with lime plantations. The profits, as a communicative

planter rashly explained to him, as it were with a view of inviting others to come and compete, are large. An outlay of 1,000L. will establish a 20-acre plantation in full working order, with works and plants complete, and defray the expenses of supervision for seven years. At the end of that time the estate would yield at the rate of 40 hogsheds of concentrated lime-juice, worth 40L each, or 4800L; while the yearly cost of cultivation and manufacture would be about half that amount, leaving 240L. as the net annual profit. If the industry is such a profitable one at the present time, the happy lime-juicers of Dominica had better rest content in their modern Arcadia, instead of bragging of their gains to the promiscuous visitor; but what prospect is there, we ask, that this rate of profit would be maintained if, say, the acreage under cultivation were doubled or trebled? So with gambier. The Kew authorities have lately been paying special attention to this valuable tanning material, and numerous attempts at its propagation are being made in the West India islands. The United States being among the largest consumers of gambier, it is certainly reasonable to expect that, if they could obtain it as cheaply at their own doors, they would not go to the Straits Settlements for it. But while we do not say that there is not room for an increased output of gambier, it should be borne in mind that its manufacture in the Straits Settlements is practically a monopoly of the Chinese, who have thus far been the only people who can make the culture pay. What Chinese competition would mean, if it is a question of producing cheaply, there is no need to particularise. Are our West Indian colonies prepared, at a time when Australia and the States are compelled to exclude Chinese from their labour markets, to rush in where the European planters of the Straits Settlements have hitherto feared to tread? It is not quite enough that the warm moist valleys of Dominica are likely to suit the gambier-plant in every way. The question is, whether the planters there could face the possibility of a fall in the value of the manufactured product to say 10L. per ton, instead of the 40L. which it realises now. Again, we are informed that "spices, such as nutmeg and mace, vanilla, black pepper, cubeb pepper, long pepper, clove, ginger, cinnamon, cardamoms are already introduced into this part of the world. The demand for spices is increasing, and these islands could grow every one of these mentioned, if only the people would give their attention to them and treat them according to their special requirements." But is it not also, that the cultivation of nearly every one of the above products is already, if not overdone, at least so fully provided for that further competition can only prove disastrous from a financial point of view? Pepper, for instance, is almost exclusively produced and brought into commerce by Chinese cheap labour; vanilla is a product the cultivation of which requires not only unremitting care but a dexterity only to be acquired by practice, and any considerable addition to the production of Mauritius, the Seychelles and Mexico, would send prices down to the lowest verge of remunerativeness. The commercial history of cubeb, records price-fluctuations from 35s. to 30L. per cwts within a few years. The increase in value of this article has led to an enormous extension of cultivation in Java, and the value of the drug—which, it should be remembered, is one of comparatively small significance—has fallen 100 per cent. within the last few months, while the exports from Java have risen from 118 piculs in 1888 to 1,373 piculs in 1890. Essential oils scarcely offer greater promise. With those which are produced in France and Italy it would require not only a considerable capital, but also a vast fund of practical experience to cope. Our knowledge of the chemistry of essential oils is as yet so limited, and adulteration so difficult of detection that buyers are compelled to rely very largely upon the honour and commercial reputation of the growers with whom they deal; hence custom and prejudice prevail in this trade to an almost incredible extent. A slight innovation—often of the nature of an undoubted improvement—in the packing of

an essential oil is usually sufficient to render the sale of the new product unremunerative, as anyone knows who is acquainted with the wholesale markets. Oils of lavender, eucalyptus, peppermint, geranium, clove, rose, petitgrain, to mention only a few at random, are already distilled in quantities which would render any further competition ruinous.

We have no desire to dissuade Colonial planters or intending investors of capital in Colonial enterprises from carrying out their intentions; we only ask that they should consider the possibility of finding a market for their product before they lay out their plantations. Otherwise it is clear that within a few years the produce markets of the world will be flooded with merchandise from the newly-acquired or commercially revived colonies in all parts of the world, for which there will be no outlet, and the disasters of the cinchona and shellac markets must inevitably be repeated on a larger scale than before.

All this is but too true; but we fear it is only preaching to deaf ears. Each man, as in the case of religious teaching, generously hands over the lesson to his neighbour, but cannot admit the personal reference to himself!

WHAT WE DRINK.

More and more beer; steady in our use of distilled spirits and wine; rather less of coffee and tea as compared with past years. This is an important study, for it has a direct bearing upon the physical and social condition of the people. A simple presentation of the figures is so forcible as to require little comment. And here they are:

PER CAPITA CONSUMPTION.

Year—	Beer, Galls.	Spirits, Galls.	Coffee, Lbs.	Tea, Lbs.
1890	13.66	1.10	7.90	1.34
1889	12.72	1.32	9.20	1.30
1888	12.80	1.26	8.89	1.36
1887	12.23	1.21	8.36	1.18
1886	11.20	1.28	9.20	1.35
1885	10.62	1.20	9.45	1.15
1884	10.74	1.18	9.16	1.10
1883	10.7	1.16	8.3	1.28
1882	10.13	1.19	8.29	1.46
1881	10.25	1.34	8.23	1.64

The decrease in the per capita consumption of coffee during the past four years, as compared with the four years 1883-86, is due to the increased cost of the article. Never so dear has it been, and it is not as freely used as was ten years ago. On the other hand, the use of beer steadily increases from year to year, leaping within ten years from 8.65 to 13.66 gallons per capita. This meant, in 1890, the use of 855,792,335 gallons, all except 2,716,601 gallons of domestic manufacture. The present consumption of foreign wines is only about one-half the quantity, as compared with the quantity used during the period 1870-74. The use of domestic wines has advanced from an average of about 20,000,000 gallons in 1878 to about 30,000,000 gallons annually for the past three years.

The consumers of the United States paid at retail for the year 1890, the following sum for drink:

Malt and spirituous liquors	\$900,000,000
An increase of \$200,000,000 in four years			
Coffee	122,500,000
Tea	30,000,000
			\$1,052,500,000

Here is spent for beverages over one billion dollars annually, or about the amount expended by the last Congress. Think of it...two thousand millions per annum for beer, whiskey, coffee, tea and a Congress. Truly we are a great people!!

The Government derives a revenue of \$107,000,000 from liquor, which is \$26,000,000 less than is required to pay pensions. It looks like robbing Peter to pay Paul.—*American Grocer.*

VALENTYN'S HISTORY OF COFFEE.

(Concluded from page 5.)

PART V.

Coffee houses at Constantinople for the accommodation of Sailors—In spite of Mandates and Edicts, the Coffee Kettle is still 'singing on the hearth' and the Turks are sipping away Coffee like mad—If a Turkish wife did not get a *quantum suffi*: of Coffee she was entitled to sue her Lord for a divorce—Peoples of rank and fashion and their *Ganymedes*—Their Silver Trays and Gold Cups—A few drops of the Essence of Amber or Clove give an agreeable odour to Coffee—Moor. Thevenot makes a Coffee Party in Paris in 1657, and invites his friends—Of the Venetians who are supposed to have been the first Coffee bibbers amongst European Nations—Petro dalle Valle once more—of the Druggists of Maracilles who carried out a *roaring trade* with the Egyptians—How certain Coffee Houses were established in that rising Town, and how certain *Moicha*:s and Brokers discussed Commercial matters and enjoyed their Pipoos therein—How certain Doctors and Physicians made another foolish attempt to suppress the use of Coffee and most signally failed—The probable supposition that Coffee was first introduced into Paris by Soliman Aga and his Retinue in the Reign of Louis XIV—and lastly how the said Soliman Aga sought an audience, which was vouchsafed to him by the French Monarch after a delay of only six months.

“Whilst Mr. G. Hand was still in Constantinople there were 2 or 3 Coffee houses at Galata for the accommodation of the Sailors in particular, though there were many more houses in the other Towns of the Turkish Empire, which were for the most part frequented by People of Learning and rank.

The Order or Mandates from Constantinople had the effect of bringing about only a more extensive use of Coffee in the other Towns, so much so, that it was taken twice a day by strangers; and besides, the Coffee kettle used to be kept in constant readiness by some in order to be able to offer to visitors a single cup at least. The custom was carried to such an extreme, that the non-presenting of a cup of Coffee, or of its refusal when offered was considered as indicative of a great want of courtesy.

Some spent on Coffee as much money perhaps as would have paid for their Wine in Paris or elsewhere; and what was more extraordinary was, that if a husband did not provide his wife with a *quantum sufficit* of Coffee, this was considered sufficient to entitle her to sue for a divorce.

People of rank and station here, have a special Cup bearer or *Kahvehgi*, and Overseer over Coffee who is stationed in a certain apartment near the hall where they generally receive company.

In serving out this beverage, it is first presented to strangers, and lastly the owner of the house, excepting when the Grand Vizier entertains Envoys at Coffee. On such occasions he drinks simultaneously with his guests. The non-presenting of Coffee, indicates a want of friendly feeling, and is commonly regarded as one of those things likely to lead to a *breach of the peace*.

Here Coffee is served out upon a varnished or Silver Tray or Salver capable of holding from 12 to 20 Cups which the wealthier classes get partially mounted with silver.

Their Cups are somewhat larger than ours, but they never fill them to overflowing.

They take it very hot without any sugar, but rather strong. At Court a few drops of the essence of Amber are added to each Cup, and sometimes a bit or two of Cloves or Cardamon or some Indian Aniseed which impart a very agreeable odour to the Coffee.

That well known Traveller Mr. Thevenot, was the first who introduced the use of Coffee into Paris on his return homewards from his first trip in 1657, when he entertained some of his particular friends and treated them to a dish of Coffee.

The Armenians also it would appear subsequently imported Coffee into France, as we shall presently see.

It is not possible to say the exact period when Coffee was first introduced from Arabia or Egypt into Europe, but the most probable conjecture is, that the Venetians and some other Italians were the medium thro' which a knowledge of it was imparted to other European Nations.

Some assert that Petro della Valle was the first who introduced Coffee into Italy, and he himself mentions in the 1st Vol. of his Work page 90, that he brought it with him to Italy in 1615, when Coffee was not even known there. It was Mr. Thevenot, however who first introduced it in France as far perhaps as its use was concerned, for it would seem that Mr. Galland's father, who was an Attaché to the Legation of Mr. de la Haye in 1644, brought Coffee into France and all it's appurtenances with him from Constantinople.

Coffee was imported to France by the Merchants of Marseilles in 1660; since which time an extensive Coffee trade was carried on by the Druggists of the place, who ordered out whole bins of it from Egypt (*doende die met geheele Baalen uyt Egypten komen.*)

In 1671 the first Coffee house was established in Marseilles near the rendezvous (*vergader plaats der kooplieden*) of the Merchants where smoking and games of all kinds were also permitted. This house was of great service to the Merchants, Mariners, and the Orientals, who were wont to meet there and discuss their Commercial affairs. This led to the establishment of many other public Coffee houses there.

Some time after this the Doctors and Physicians came forward with serious objections to the use of the beverage, which they said was very prejudicial to health in that dry and sultry Region. These objections were treated at first very much in the same way as those that were raised in Mecca, Cairo, and Constantinople, but with this difference, viz. that there the objections were taken on religious grounds, and here on the score of health.

Hereupon there arose public differences, discussions and polemical controversy (1679) and Coffee was denounced on account of it's dry and hot properties, and on account of the powerful effects it produces on the brain, causing thereby too profuse an evaporation of the bodily fluids, whilst it at the same time obstructs the pores of the coarser parts (*de grove deelen*) of the body and induces the animal spirits (*dierlyke geesten*) which bring on sleep, to ascend into and penetrate the brain, by which means the sinewy sap (*de zenuw-zappen*) which is so essential to the restoration of health becomes entirely absorbed and the sinews themselves relax and lameness and other bodily infirmities ensue.

And further that by the sharpness and dryness of the blood, which is entirely burnt up (*door de scherpeheid en droogte des bloeds, dat reeds als geheel verbrand is.*) the different members of the body are so completely drained of their essential fluids, that the body itself must necessarily become enfeebled and emaciated; and those especially, of a sanguine or melancholic temperament or who have a hot liver, like brains and fine spirits (*en die genen, die een heeterer, sulke hersenen en fyne geesten hebben*) are most liable to suffer from these effects, which are produced by the noxious and unwholesome properties of Coffee.

All this stir and opposition ended at Marseilles much in the same way as the clamour which had been raised by the Priests at Mecca, Cairo, and Constantinople, nor did it in any way check the use of Coffee in that town, or it's neighbourhood; but on the contrary it laid the foundation of a successful trade there and at Lyons, to which places large quantities of Coffee were imported from Egypt and Smyrna.

Prior to the year 1669 they knew nothing of Coffee at Paris; and indeed nothing more was known or heard of it earlier than 1657, beyond Mr. Thevenot's allusion to it, and the casual accounts given of it by some travellers.

The most probable supposition is, that Coffee was first brought into Paris, when Soliman Aga, was sent as an Envoy there by Mohammed the IV. to Louis

the XIV., and that large quantities of it found their way into Paris thro' the followers or retinue of Soliman, who made presents of it to the Parisians.

This ambassador arrived in Paris in July 1669, but had audience only on the 5th December, and quitted Paris in May 1670, and it was at this time that the use of Coffee became properly known in Paris and the demand for it became gradually so great, that large quantities of it were obtained from Marseilles for consumption."

PART VI AND LAST.

In 1672, an Armenian comes over to France and opens a Coffee shop, but is obliged to shut it up for want of Customers.—Some years after another Armenian, Maliban, attempts a similar thing, but in spite of the free-pipe offered by him to his Customers he is also obliged to shut up shop and cut to Holland—Gregor, Makara, and Gantoise meet with a better fate and Vent Coffee more successfully.—Of the little cripple Candiot who dragged himself along the streets and sold Coffee sweetened with sugar; and of Stephen of Aleppo and others from the Levant who could not compete with some sharp Frenchmen who had established splendid Coffee houses in Paris which in a short time became the resort of the "great and the high born"—The great Coffee controversy in France.—The question is put to the vote and there appears in favor of Coffee, Monsieur Andry; against it Messrs. Duncan of Montpellier and Hecquet of Paris.—The Nobs have it—Coffee finds its way across the Levant to France—Thence to London and thence to Holland and the principal Towns.—Meets with a barrier in Holland but overleaps it—Helvetius, a German, writes a little work in favor of Coffee, which never sees the light, and a celebrated Physician Bontocoe also writes a very luminous treatise on Coffee and dilates upon it's great virtues—Numberless Coffee houses spring up in Holland, and every man, woman and child therein partakes of it freely—Dutch hospitality incomplete without a cup of Coffee being offered and swallowed—Coffee versus Beer—if some people chose to take a grog after Coffee, by way of a *Dinnerlick*, it is no fault of ours—Brutes will be brutes—The moderate use of Coffee recommended and Domestic and others exhorted not to indulge in what is called "Perpetual sipping"—The Author bids his Readers adieu, slips upon the saddle of his Dromedary and is off to Persia.

"In 1672 an Armenian named Pascal came over to Paris, who sold Coffee openly at the Fair of St. Germain and subsequently established a permanent shop there and served out Coffee at 2 stivers and 6 Deniers the Cup; but as his shop was frequented by only a few strangers, he was soon after obliged to give it up.

After an interval of 3 or 4 years, there came another Armenian to Paris named Maliban who vended his Coffee in a certain street there; indulging his Customers, at the same time, with a pipe, but this also did not last long, as he had to leave the place for Holland.

He left, however a substitute, a youth, named Gregor, whom he had brought with him from Ispahan and who died in an advanced age. Gregor was succeeded by a Persian named Makara, who, after having carried on the business for a time, returned to his native land, leaving one Gantoise, a Liege, in his room.

In former times a little Cripple by the name of Candiot was seen walking the streets who used to sell Coffee sweetened with sugar at 2 stivers each cup. He was assisted in this traffic by a mate.

Eventually there came another called Stephen of Aleppo. These were the first Coffee houses. Afterwards, there came over many others from the Levant, who however, in the very commencement made but very indifferent sales, owing to the paucity of Customers of any respectability who ventured to enter these Coffee houses, especially on account of the smoking and the drinking of Beer which was tolerated therein. But shortly after Frenchmen themselves established similar houses and began to serve out Tea, Chocolate and other beverages with the allowance

practically sterilised when it contains only from 1 to 3 per cent. of coffee extract. One is glad to hear coffee so well spoken of, and bushmen and travellers in Australia ought to take it instead of tea, inasmuch as coffee requires cooking (ought to be boiled and produced as a decoction), but this process really converts tea into a dangerous fluid, for tea should never be drunk except as an infusion.

Some valuable botanical experiments in the life-history of green leaves have recently been published by Professor Schimper. They relate to practical experiments made by himself on the part played by mineral salts in the economy of plants. He shows that, immediately on germination, the phosphates begin to leave the seeds. In conjunction with organic substances, their ultimate goal is the growing point and the *mesophyll* (or middle substance of leaves). The mineral acids, he shows, pass through the inter-cellular parts of stems and leaf through which the sugars and *amides* also pass. Potassium passes upwards out of the seeds as potassium phosphate. The leaves of the vine plant more particularly (and this ought to interest Australian viticulturists) contain, in addition to oxalate of lime considerable quantities of tartrate and malate of calcium (or lime). Lime has practically (by a student of organic chemistry) to be regarded as a carrier of other and perhaps more important and fragile chemical particles to the parts of the growing organism where they are required, and where, as in a market-place, they are immediately picked up. Then the "carrier" (*lime*) returns to the earth as it was, as it does in the case of old bones which dead men and animals cannot walk about with.

One important botanical fact has recently been proved—that plants can be sterilised. This is effected by parasitic fungi attacking pistils and stamens respectively, and, of course, destroying them. There is a tsudecy among botanists to believe this may have been the inducing cause of the organisation of *monocious* and *dicocious* plants, which are not confined to any particular botanical order, although they are more abundant in some than others. *Monocious* (one household) signifies that pistils and stamens are found of the same plant, and *dicocious* (two households) on separate plants.

A French wine merchant, M. Girard, has for some time past been undertaking practical experiments to prove the possibility of profitably growing potatoes for the manufacture of potato brandy. He decides it is an industry which cannot fail to be commercially successful. Only ought not the words "potato brandy" to be on the label of each bottle?—*Australasian*.

BURNT EARTH.

As the subject of burnt earth is commanding a good deal of attention from gardeners at the present time, and we think properly so, a few words upon the scientific side of the question may not be out of place.

The improvement of sterile soils by burning is a very old practice, and was known to the Romans. The theory of its operations has occasioned much discussion, both among scientific men, horticulturists, and farmers.

It is quite evident, however, that the action of burning a soil is not a merely mechanical one of opening the texture, but is decidedly chemical.

The burning process does not answer on all clay soils, but it does answer on most of them, especially on the Oxford clay, which crosses England in a wide band; it answers also in Essex, Cambridgeshire, Bedfordshire, and in Worcestershire.

The operation renders the soil less compact, less tenacious, and retentive of moisture; and when properly performed, it converts a substance that was stiff, damp, consequently cold, into one powdery, dry, and warm, and much more suitable as a bed for vegetable life. A plant to grow up strongly and freely, must have not only good and abundant food, but a suitable and healthy abode; it must be well fed and well bedded.

The great objection usually made to burning soils is, that it destroys vegetable and animal matter, or the manure in the soil; but in cases in which the texture of its earthy ingredients is permanently improved, there is more than a compensation for the temporary disadvantage. It must always understand

that the ashes of burnt earth are best when they are blackest—that is, when produced by slow combustion.

The burnt substance, when mixed with other soil, makes it work more easily, renders it more friable and less tenacious, and tends to make strong, thin, sterile clay-soils less compact, and more productive. The vegetable matter which was burnt is quickly converted into an enriching ingredient, which in some classes of soil may lie dormant for ages. Whenever there is an excess of inert vegetable matter, the destruction of it by fire is most beneficial; the ashes being mixed with the soil produce vigorous and healthy plants on ground which before was unproductive; burning, therefore, destroys the inert vegetable matter of a soil, and converts it into a valuable manure.

In well and satisfactorily burnt earth, it is estimated that about one-sixth of its weight should be destroyed, the other five-sixths being brought into more vigorous action, and resulting in positive good. On the other hand, coarse sands, or rich garden soil, whose texture is already sufficiently loose, and the organic nitrogen sufficiently soluble, the process of burning must be detrimental.—J. J. WILLIS, Harpenden.—*Gardeners' Chronicle*.

SALT IN AGRICULTURE.—A further communication from "B." in regard to the use of salt in agriculture has been sent us for publication. He gives us some curious information about the use of salt for cattle and the effect it has upon the production of milk, and mentions the custom of placing a block of rock salt in the stable for cattle to lick. This was—and probably is still—a common thing in country in cattle-sheds, and perhaps "B." may not be aware of the manufacture of cylinders of salt on a metal spindle which can be hung up in convenient positions in the sheds or out of doors. As regards the working of the ground in the Mahaoya valley, has "B." ever tried thatching the ground with manure grass or other vegetable litter? We have seen wonderful results from this operation in a dry district in country; whilst the rest of the estate was absolutely burnt up and drooping and the surface as hard as a brick, the soil beneath three or four inches of thatch was always moist and friable. The grass itself was fired into tinder and thence rose the danger of fire, which was only avoided by a liberal sprinkling of earth over the thatch. If "B." will point out to Mr. Dawson how he proposes rendering the salt unfit for human food, it is very probable he would be allowed to make a trial.—*Local Times*.

THE TALLOW TREE IN CHINA.—Mr. Hosie, the British Consul at Wenchow, in his last report describes a curious vegetable product which is cultivated in his district. This is the tallow tree (*Stillingia sebifera*, Roxb.), the fruit of which produces oil as well as tallow. The berries, which resemble coffee-beans in appearance and size, are first steamed and then pounded in an ordinary rice-trough. By pounding the soft mealy mesocarp is partially separated from the kernels. The whole is then placed in a bamboo sieve, the meshes of which are just large enough to allow the mealy matter to be scrubbed through, and small enough to keep back the kernels, which are hard, black, and about the size of peas. From the mealy matter the tallow is expressed in primitive wooden presses. To obtain oil the kernels are dried and passed between two millstones held at such a distance apart by means of a bamboo pivot as to crush the hard shells of the kernels without injuring the white interiors. The whole is then passed through a winnow, which separates the broken shells from the solid matter. The latter is then placed in a deep iron pan and roasted until it begins to assume a brownish colour, the process being accompanied by continual stirring to prevent burning. The crushed shells make an excellent fuel for the purpose. It is then ground by a large stone roller in a circular stone well, steamed, made into circular cakes with bamboo and straw casings, and passed through the wooden press. A good lighting oil of a brownish-yellow colour is thus obtained. The allow is called "p'iu"—that is, skin, or external, oil.—*London Times*.

MR. THOS. CHRISTY, F.L.S.

If flesh still be heir to any ailments for the cure of which no "new drug or remedy" has yet been found, no blame attaches to Mr. Thos. Christy, of Lime Street and Sydenham. He at least has done all that mortal man could do to secure his fellow-creatures such relief as the introduction of some three or four hundred new remedies may be able to afford. On African fish-poison and chillbain-cures, on kola-nuts for the interperate and strophanthus for the weak of heart on Myocom fly-gum and jambul, Mr. Thos. Christy is regarded in Mincing Lane as the fount of all wisdom. The recent addition of Christy to the armoury of surgical appliances, and the reflection that the garden of Mr. Christy's residence at Sydenham would look at its best on a genial spring day, caused our town traveller to take a trip to the neighbourhood of the Crystal Palace in search of new information. Mr. Christy was found engaged, as represented on our picture, in the critical examination of a spurious kola-nut, an object which he holds in particular horror. "It is a most extraordinary thing," he said—"the most wonderful thing that has ever come under my notice—how these natives go on shipping spurious kolas, though we have explained to them most carefully that they could not be too particular in sending over only the genuine kolas of the *Sterculia acuminata*. You have no idea of the wonderful action of the true kola as a nerve stimulant and a remedy for dipomania. Thousands of unhappy patients are pining because we cannot supply the true drug fast enough, while these vile substitutions with which our markets are flooded are bringing the drug into discredit." With that Mr. Christy dismissed the spurious kolas, and took our man for a walk through the hothouses in which he rears thousands of young plants from seeds and cuttings, and whence scores of tropical plantations annually receive a supply of economic plants, natives of other tropical countries, for acclimatisation. The first hothouse contained hundreds of young camphor-plants, all propagated from seedlings which Mr. Christy obtained from China some years ago. He considers the camphor-tree a particularly suitable one for acclimatisation purposes, and has already forwarded consignments from Sydenham to intending cultivators in South Africa and California. From his buyers in the last-named country, who have now had their supply in the ground for about four and a half years, he hears favourable reports. Close to the camphor-trees are numerous specimens of the large green and gold-leaved *Pothos oris*, a plant much sought after for the purpose of table-decoration; of the upas-tree from Java, which in this hothouse has attained an average height of 3½ feet, but grows to a height of 60 feet in its native country. From a German firm of chemical manufacturers, Mr. Christy told us, he has a standing order for all the sap or milk from the tree which he can supply. The *Strophanthus hispida*, with its bright green, soft, hairy, lanceolate leaves, is there; and so are the Chinese ginseng and the avelon. The specimens of the latter however, are almost leafless, and the milk, which has strong caustic properties and is recommended as a specific for cancerous ulcers, is exhausted. In another hothouse we had occasion to admire a large number of vigorous specimens of several varieties of coffee—the large-leaved Blue Mountain coffee from Jamaica, the Maragipo, the Arabian variety of the Liberia coffee, and many others. Mr. Christy, as he explained to us, has established relations with a great many planters and explorers throughout the tropics, who supply to him the seedlings or cuttings of plants which they grow, and obtain from him in return the exotics they desire to introduce for commercial purposes. A side of one of Mr. Christy's hothouses is filled with young patchouly-plants, for which he has had a very considerable demand of late, in spite of the fact that, commercially speaking, the perfume is already produced to excess. The Jambul plant (*Syzygium Jambolanum*) is propagated at Sydenham from fruit. Of the *Strophanthus glabrus* from the Gaboon, Mr. Christy possesses only a single specimen,

and that is only about 1 foot high and does not present a particularly flourishing appearance.

In a special hothouse, the temperature of which is kept higher than that of the others, some thousands of vanilla plants are grown. They are beautiful orchids with thick, bright green, smooth, lanceolate leaves, but they are of very slow growth, the majority, which had been in the hothouse for over six months, being only about 3 inches high. They are kept until they have reached a height of 1½ to 2 feet before they are distributed. Of cubeb pepper there are three varieties at Sydenham, including the large-leaved "Omeo" variety, which is a very scarce one. In another portion of the same hothouse about 30,000 kola-nuts are placed in boxes for propagation, but only a very small proportion—less than 15 per cent—Mr. Christy thought will germinate.

Two of the hothouses at the time of our visit were set apart for the manufacture—or, rather, the bleaching—of Christy, the new surgical dressing which has recently been placed upon the market, and which Mr. Christy expects to supersede the dressings now in use. The fibrous material from which the Christy paper is manufactured, after being soaked in a solution of bichromate of potassium and treated with glue, is hung up to dry and bleach under glass, as is shown in the above illustration. Mr. Christy expressed himself as highly pleased with the success of this novelty, and told us that, in spite of certain attacks which had been made upon it by rival manufacturers in Germany, the sales of his product in that country and in other parts of the Continent were so large that they were frequently at their wits' ends to keep pace with the orders coming in.—*Chemist and Druggist*.

WYNAAD NOTES.—Crop prospects may be generally regarded as very fairly favourable; and a corresponding cheerfulness would reign amongst us could we all feel that our future was as secure as our next crop. But there is no use in atomizing concealsment in a matter which is every day becoming more patent to the experienced coffee-planter. The death warrant of Arabica has gone forth, and it must be only a matter of a few years, when it's place amongst us will know it no more. The old fields hold on where the borer does not finish them, but the present heavy crop will probably shake many of them beyond recovery. The disheartening fact is that it is the young plantings on which we should naturally rest our hopes, and these are proving a constitution so undermined by leaf disease that it is not probable that even the most promising of them can be lasting. I do not think from what I can gather that the idea of grafting coffee is regarded as feasible in the Wynaad. A very great deal of Liberian is being planted in this district. It has the advantage of course of being longer in reaching maturity, but if we can hold on with our remnants of Arabica until the Liberian comes into bearing, we may hope for better times before us yet. There is much depression felt on account of the shockingly bad price given us for last season's eluchona bark. A great quantity was despatched from this district in the hope of replacing some of the losses incurred by the failure in our coffee crops. But as ill luck will have it the sales have proved generally so unremunerative that it is absolutely hardly worth while harvesting our bark. A good deal of business is being done in timber, and our magnificent Blackwoods are paying the penalty of their lives for our necessities. This is likely to be an improving trade. Very large quantities of "fancy blocks" are in demand for the Continent, and one thinks with regret of the glorious timber which lay rotting in our fields, or became fuel for our coolies in the good old times, when we sacrificed the most valuable trees, simply because we wanted the land, and had no roads by which to transport the wood to the coast. Certainly we are better off in this respect, and our roads are, some of them, becoming a pleasure to travel upon.—*Madras Times*, May 15th.

EFFECTS OF THE EARTHQUAKE OF APRIL 7TH ON THE TIDES AT TANGALLA.

The interesting account by Mr. Surveyor Erskine of the violent perturbations of the sea at Tangalla, during the earthquake period early in April, which account we owe to the courtesy of Government, will excite general attention and will be carefully studied by scientific men. As we have heard nothing from the great volcanic centres of the east, we feel justified now in tracing the successive disturbances of earth and sea to some subterranean or submarine volcanic cavity immediately beneath our island,—not a very comforting conclusion to arrive at. But we should like to have the opinions of scientists, such as the Royal Engineer Officer who acts as Surveyor-General, Mr. George Armitage and others on this question. Some day we may have a quake which will do something more than "shake the isle from its propriety."

THE EARTHQUAKE AT TANGALLA.

Surveyor-General's Office, Colombo, May 6.

The Hon. the Colonial Secretary.

Sir,—I have the honor to forward herewith an interesting report by Mr. Erskine, District Surveyor in charge of Tangalla Bay surveys, with reference to a disturbance in the tide at that station on the day of the recent earthquake. No doubt many would be interested in the memorandum who would not see an ordinary official report on the subject, and I would therefore suggest that it might with advantage be sent to the several papers for publication.—I have, etc., (Signed) FRANCIS J. DAY, Major R.E., Acting Surveyor-General.

Tangalla, April 13.

The Chief Surveyor, Southern Province.

I beg to report that owing to the unsettled state of the water combined with the high tide on Wednesday I gave orders for the tide box to be removed; otherwise it may have got seriously damaged and washed away.

There seems to have been some unusual disturbance of tides since Saturday night, the 4th instant. The gauge pencil was not marking the paper as it had hitherto done. On this night the pencil line on paper had the appearance of being slightly shaken, thus marking an irregular pencil line about quarter of an inch broad. Nothing unusual happened till Tuesday, the 7th instant. I registered the tide reading in the morning, and after returning from work at sea about 11 a.m., I noticed it had registered high tide and was falling and had fallen one foot in the short space of three hours. Usually high tide at this period is at 1 or 2 p.m. Curiosity took me down again to the tide gauge at 1.30 p.m. when I was still more astonished to find the tide had risen to three feet on the box in two hours and a half. Fearing something might happen I stood by the box and watched the movements of the indicator. At this stage I took off the pencil as it had gone above the paper. At half past three the indicator went up to the top of box and would have gone higher if the indicator could have registered the reading. The highest reading on box is 3.70. The low tide today registered 0.64, and I am certain the high tide would have been 4.50. During this time there was a continuous rise and fall of eighteen inches below the level of top of box at intervals of 10 and 20 minutes; at these intervals the water round about appeared to rise in one volume, receding very quickly but generally falling to the same level.

In case of an accident to the tide box, I took a reading on to a B. M. on rock close by and stayed on till 4.30 p.m. At this hour there was very little abatement of the tide. Mr. Grey was busily engaged with all hands repairing the breaches as soon as possible.

On Wednesday morning I visited the tide gauge but found the tide had been normal at low but 3.43 high during the night. I left Mr. Grey to supervise the repairs to breakwater. After breakfast I sent him down at 11 a.m. to carefully watch and let me know if there was a repetition of the day previous.

The tide during the day was again noticeable from its extraordinary movements. Mr. Gray informed me that the tide registered 2.80 on the box at 1.30 p.m.; at 1.45 p.m. it suddenly rose to 3.30 and receded very soon again to about 2.80; at 2 p.m. while he was watching the movements of the pencil, the indicator suddenly rose again, (this time to top of box) with great force and immediately receded. The level of the water was within an inch or two of zero of box. On this occasion high tide may have registered five feet. From this time until 5 p.m. the tide rose on several occasions to top of box but not with such force as at 2 p.m.

The tide box was now in danger of being washed away. I gave orders for its immediate removal. The sand bags weighing 240 lb each were swept away in every direction. (Signed) H. ERSKINE.

A NEW ARTIFICIAL QUININE.

When an announcement is made nowadays that some chemist has discovered the way to make a complicated organic compound, which only Nature hitherto has been able to fashion, there are two methods of treating the matter: either with uncompromising scepticism, or unbridled enthusiasm. Should the organic substance be quinine, then there is a chance for buyers thereof to paint in dull colours the future of the cinchona industry, in the hope of buying the alkaloid cheaply meanwhile. Such people might have a very good innings this week, for we hear from Paris that Grimaux and Arnaud, two chemists whose reputation places them above suspicion, have succeeded in producing quinine artificially; that is to say, they have converted commercially worthless cinchonine, the peculiar alkaloid of *Remijia* bark, into the more valuable quinine. Their process seems theoretically correct. Cinchonine is an alkaloid differing from quinine to the extent of CH_2 , viz.:—

Cinchonine has the property of combining very readily with alkalies and other bases (upon this depends the B. P. test for its detection in quinine) to form definite crystallisable compounds. Thus the sodium one is $\text{C}_{19}\text{H}_{25}\text{NaNO}_5$. Hesse, the German chemist to whom the Hanbury medal is to be awarded on May 26th, was the first investigator to establish this, and he conceived that it might be possible, by introducing a methyl-group, CH_3 in the place of the sodium, to produce quinine. He tried this by converting sodium-cinchonine into silver-cinchonine, and acting on the latter with methyl iodide. The result was the production of methyl-cinchonine iodide, $\text{C}_{19}\text{H}_{22}\text{N}_2\text{O}_5\text{CH}_3\text{I}$, and from this, unfortunately, only the iodine atom could be abstracted, and no one of hydrogen along with it, which would have left quinine, or an isomeride thereof. This was an interesting synthesis, and the product, monomethyl-cinchonine, was not unlike quinine in some of its properties—as, for instance, in giving the green reaction with chlorine and ammonia. Whether Grimaux and Arnaud have profited by Hesse's experiments or not we are not in a position to say definitely, details being wanting, but it would appear that they have, for their process of converting the cinchonine into quinine is in two stages, like Hesse's—viz., (1) production of sodium-cinchonine, and (2) acting upon that with methylene chloride, CH_2Cl_2 . By so working, it is stated, "there is obtained a body which is identical with natural quinine, and, by substituting ethylene or higher derivatives for the methylene compound, substances analogous to quinine are produced, which, it is believed, may possess most interesting medicinal properties."

The reason why methylating failed in Hesse's case was owing to the sodium refusing to join hands with the iodine, preferring union with hydroxyl, or a

hydroxyl equivalent present in the secondary reagents employed. The reaction was, therefore, such a one as:—

A little juggling on paper makes the product

but this does not happen in practice. The iodine atoms behave as if it were linked with all the rest of the atoms in the molecule as a whole, that is, as if it were $C_{20}H_{14}N_2O_2I$. It will be seen from this wherein lay Grimaux and Arnaud's opportunity. They take a methylene compound, produce $C_{10}H_7N_2O_2CH_2Cl$, or, substantially, $C_{10}H_7N_2O_2Cl$, out away the chlorine from it, and quinine is left.

As a chemical achievement this success is noteworthy, but it comes five years too late to be of much commercial importance. Coprae hark as a member of the materia medica is almost dead. It does not pay to go into the primeval forests in the centre of South America, fell giant trees, strip the bark and bring it on mules' backs to the coast, thence to be shipped to London to compete with cinchona. The influence of the discovery upon the quinine market may therefore, apart altogether from the cost of production, be set down at present as *nil*. But it is certainly gratifying to know that quinine has been made artificially, and even if Grimaux and Arnaud's article turned out to be the isomeric quiniidine, that would be no less interesting. Of course the achievement throws no light on the constitution of quinine, which stands as Skrap has left it—viz., that it is a derivative of paramethoxy-quinoline. Isomerides of quinine have been prepared. The first was about five years ago by Dr. C. A. Kohn, its empirical formula being the same as quinine, but constitutionally it was by hydroxy-hydroethyloequioline.* There is little in common between this and quinine. Another isomeric substance was made fully a year ago by Wallach and Otto. It is Binolentrol-beta-naphthylamine, and its solutions, as well as solutions of its salts, are highly fluorescent. This substance was referred to at the time as an isomeride of camphor, which obviously is a mistake, seeing that it contains nitrogen and has an empirical formula the same as quinine.—*Chemist and Druggist*.

REVOLUTION IN JEWELLERY.

The discovery of a new "dry digging" in South Africa follows hard on the announcement of M. M. Frémy and Verneuil's success in manufacturing rubies. The civilised world was discussing that event a few weeks ago, and trademen interested found it necessary to send reassuring circulars to the press. Their ingenuity will be taxed to furnish comfort under this latter blow, if rumours prove exact. The position of the new field and the circumstances of its identification are not yet clear. But we learn that the Company has bought it for £100,000, that a multitude of diggers have "rushed" the spot, and that the finds, so far, promise another Culeberg Kopje. It is bad news for owners of diamonds, and, in fact, for everybody else except the few who will make money out of their claims. Even the revenue of Cape Colony will not benefit—quite otherwise. The historic housewife who killed the goose with the golden eggs supplies a precedent.

Supposing these reports prove true, as seems likely, and also that M. M. Frémy and Verneuil achieve all that they confidently expect, as seems more likely still, a revolution must follow. Well-informed persons who exact value for their money have long been reluctant to buy diamonds. They looked for the news which has now arrived; and if it should turn out false this time, their expectation will rest as firm as ever. That there are dry fields in South Africa—fields, that is, where gems are found *in situ*, where they were crystallized—is as certain as facts undemonstrated can

be. If only one of them fall into the hands of independent diggers, the market will be upset; the lively old times will return when a casual fellow-passenger by 'bns may have a pocketful of diamonds consigned to him by a lucky friend or brother at the Fields. Under such conditions already the great merchants have been driven to despair, and the confusion would be vastly worse now. As for the triumph of the French chemists, it is clear that if they can make rubies hard enough to be employed as pivots in watches, and "much larger," the time is near when they will produce stones of any size to order. Thirty years these gentlemen have worked, and their progress has been so slow that it is likely to be sure. Within the last few months only, as they tell us, the secret of making large gems has been traced out. But if rubies can be manufactured, all the great class of crystals to which they belong can be manufactured also. It is simply a question of the colouring material. The same process, with blue substituted, will yield sapphires with orange-yellow the grand Oriental topaz, and so forth. Pearls, emeralds, and opals, in fact, among gems of the first class, will defy M. M. Frémy and Verneuil for the present.

It is a very uncomfortable prospect for holders of family jewels, but the *vacuus viator* who is a man of taste does not lack consolation. Flashing diamonds and gleaming rubies are vastly pretty but essentially barbaric. That term is used now for Oriental jewellery, which to a cultured and thoughtful eye is the perfection of art in its style. What is meant by the word "barbaric" used in reference to such matters? Most people would answer, an ostentatious display of costly material unrefined by art. It is properly employed in describing the paraphernalia of an Ashantee chief, whose arms are so loaded with nuggets of pure gold that he has to rest them, outstretched, upon the shoulders of a slave preceding him. It is properly employed in speaking of the old Turkish ornaments—a confused medley of precious stones which one need to find in the Ezenstan at Stamboul but few remain at this day. Not improperly also it may be applied to the massive rings, bracelets, and such articles, which are especial favourites with our countrymen "not so much but not gaudy," as they say, massive gold of twenty-two carats, with a great flaming diamond or group of gems solidly set therein, with no "gimcrack" about them; nothing but honest gold worth so much and stones worth much more. The value is obvious—an expert can calculate it at a glance. Money is not wasted on design or charm of fancy. An idiot who had the use of his hands and had served an apprenticeship to a good craftsman could make the thing as well as the best Paris artist. This represents a step beyond the Ashantee ebboeces; but it is the same in principle: a display of mere wealth. But the term "barbaric" could never be used, by a thinking person who has an eye for beauty, towards the jewel work of Cashmere, for instance, or Jeypore. For its value lies in the art alone. The gold may be beaten as thin as tissue-paper, the gems may be mere scales and chips which an English artisan would not pick up. These things are simply vehicles used by the artist to produce his effects of colour. Sir George Birdwood says, speaking of the best Indian goldsmiths, "by their consummate skill and thorough knowledge and appreciation they contrive to give to the least possible weight of metal, and to gems absolutely valueless, the highest possible artistic value, never even in their excessive elaboration of detail, violating the fundamental principles of ornamental design nor aiming to please, even though it be an effect of barbaric richness and superfluity." We may well ask where the "barbarism" comes in if the work be of "the highest possible artistic value"?

Such ideas must needs be eradicated when gems cease to represent a great sum in money. They will then fall to their proper use, that to which the Indian artificer has always put them. He will make jewellery to the Rajah's order as expensive as may be desired set with great stones; but his taste prefers to work upon these chips and scales, using them as points of luminous colour in a thoughtful composition. Therefore

* Quite so!—Ed. T. A.

he does not wish his precious stones to sparkle—distracting the eye. The Hindoo's notion even in cutting gems, is to make them shine. Our self-sufficiency attributes to ignorance or want of skill an effect which in truth, is the result of a taste more delicate and finished than ours. We think that the Oriental would have brilliant and roses, and the rest, if he could—a grotesque error. Everybody nowadays, or almost everybody, is prepared to laugh at the verdict of the jury delivered after the Great Exhibition of 1851. "To cast a glance at the jewellery of India," said that amusing record, "is enough to convince us that these nations have remained stationary from a very early period of manufacture. Some of them, indeed, develop ideas full of grace and originality, but their productions are always immature and imperfect; and the skill of the workman is called in to make amends for the inadequateness of the manufacturing process." The Philistine never made a more striking declaration of faith. We have left that a long way behind, anyhow. When precious stones generally lose their value it may be hoped that we shall take a greater stride for jewellery than will show not so much the length of the buyers' purse as the quality of his taste.—*St. James's Budget.*

THE PERFUME INDUSTRY AT GRASSE.

In an article on "Grasse and its Perfume Industry," published in the *Pictorial World* of April 18th some account of the old town is given, with views of the Grand Hotel, where the Queen has been staying, the cathedral, and some of the scenery in the neighbourhood. The proprietors of the *Pictorial World* have been good enough to lend us one of the engravings, representing an interesting scene in one of the large perfume-factories of the place. The women shown in the picture are all engaged in separating the pistils from the petals of roses previous to using the latter for "rose pomade." The photograph from which the view was taken and the following particulars were supplied to the *Pictorial World* by Mr. J. E. Holdsworth, son of a member of the well-known firm of Osborne, Banor & Cheeseman, the perfumers of Golden Square. Mr. Holdsworth, junr., it is stated, has had the opportunity of becoming practically acquainted with the subject, having studied the manufacture of floral products at M. Bruno-Court's factory.

There are processes for extracting perfume from flowers; the hot process, or maceration; the cold process, or *enfleurage*; and distillation by steam.

The hot process consists in throwing the flowers into hot grease directly they are picked; after a given time they are strained off, but as they take up such a quantity of grease, they are wrapped up in cloths and pressed by hydraulic pressure. Every day fresh flowers are put into the same pomade, until it is at full concentration.

In the cold process the flowers are laid on cold pomade, which is spread on pieces of glass, about two feet square, in a wooden frame; the glass is covered with pomade on both sides, and the frames are stacked one upon the other, thus making a kind of box which fits so well that it is almost air-tight. This process is also continued until full concentration is obtained.

The floral season commences in January with the violet, the perfume of which is extracted by the hot process. Next follows the jonquil in March, from which the perfume is extracted by means of the cold process. From the middle of April until the commencement of May comes the *reseda*, or *mignonette*. Then in May commences the busy season for Grasse; women and children are employed in all the factories to pick the pistils from the rose-leaves, as the latter are only used for the "floral pomade."

The leaves are thrown into baskets, and are at once treated by the hot process; and this is continued until the middle of June. The orange-flower blooms the same time as the rose, and is treated in the same way.

What surprises the stranger most is the enormous quantity of bloom; it is not spoken of by the pound, but by the ton. The work of picking makes a long day's

labour; as it is essential that the flowers should be treated while they are perfectly fresh, it is necessary to commence work as early as four o'clock in the morning, and to continue sometimes until midnight.

From July to September come the *jasminu* and *tuberose*, which are treated by the cold process; and the season closes with *cassie* in December, treated by the hot process.

The third process, distillation, is carried on all the year. There are only two out of all the flowers mentioned that are thus distilled; they are the rose and orange-flower. The rose gives very little otto of roses, but is distilled mainly also for the "rose-water"; the orange-flower gives an oil called "neroli" and orange-flower water. When the above-mentioned flowers are not in season patchouli leaves, cloves, geranium, &c., are also treated by distillation.

During the Queen's visit to Grasse she has visited the factories of M. Bruno-Court and of M. Chiriz. At the works of M. Chiriz the last of the violets and jonquils which will be used this year had just been received, and before the Queen arrived, the floors of the quadrangle and the rooms to be visited had been carpeted with them. The Queen saw in operation the processes of capturing these odours, and as Her Majesty left M. Chiriz presented a basket of perfumes beautifully displayed in a bed of violets and decorated with apple-green ribbons and Marrocobal Niol roses.—*Chemist and Druggist.*

SPURIOUS CUBEBS.

We had our attention called some weeks ago to the offer of an Amsterdam firm to supply to English houses "spurious cubebs for druggists' use," says the *Chemist and Druggist*. We have been fortunate in securing a sample of these, and of three kinds for distillation. Of the latter, sample *a* consisted of extremely small and shrivelled berries of a black color, mixed with stalks, most of which were smooth and some showed the characteristic markings of the piper rachis. The sample contained 100 grains of stalk and 440 grains of berry. The latter was very deficient in aroma, and unlike immature cubebs, did not give the crimson colored reaction with sulphuric acid. The impression left from the examination of this sample was that the berries had already been in the still; were the feeble aroma due to immaturity, we should have expected to get a better cubeb in reaction. Against this supposition it may, however, be stated that last week 60 bags of similar berries were disposed of in Mincing Lane. These were of direct import from Singapore. Samples *b* and *c* were recognised as true cubebs, differing only in proportion of stalk, and *c* showed the presence of a small percentage of the unnamed cubeb substitute which is more globular and larger than the true berry, but is not Piper crassipes. Sample *b* contained 205 grains of stalk, chiefly hard rachis, to 360 grains of berry. The sample was rich in essential oil. Sample *c* contained 130 grains of very hard rachis to 300 grains of berry less abundant in oil than the former. Sample *d*, "spurious for druggists' use," was the fruit of Piper crassipes. Apart from the question of admixture with spurious fruit, the proportion of stalk is a matter which distillers should look into more carefully than they do. Cubebs yield from 12 to 16 per cent. of essential oil, and the stalks only 1 per cent.—(frequently less. While their presence is not objectionable, the fact that to the eye sample *c* contained less than *b*, while it actually showed about 6 per cent. more, is a sufficient argument for more careful consideration on the part of buyers. The question also naturally arises "Do all these stalky cubebs go into the still, or may some not find their way into the mill?" That can only be determined by microscopic examination of the commercial powder, and comparison with the histological characters of cubeb stalks. It may be mentioned that what we have estimated as the best of the three distillation samples was the lowest priced. We learn regarding

the spurious cubabs that 150 bags of them were imported into Amsterdam last year, and were sold at 3s. per lb., this being the limit fixed by the growers in Java. It is from the East Coast of Java that they are imported.—*Oil, Paint and Drug Reporter.*

IMPORTANT SALE OF FOREST LAND.

Today (May 18th) an important sale of virgin forest and took place in the premises of Messrs. Geo. Armitage & Co. regarding which the following letter will be read with interest:—

Office of the Colonial Secretary,
Colombo, May 18th, 1891.

To Messrs. Geo. Armitage & Co.

Gentlemen,—With reference to my telegram of the 20th ultimo, in which I desired to know, on behalf of the Government, the lowest price at which the forest land in Udapussellawa belonging to the estate of the late Mr. C. H. de Soysa would be sold, and to your reply that the owners insisted on the land being disposed of at auction, I am desired to inform you that the Government, after due consideration, has concurred with you in thinking that the course proposed by you is the fairest way of ascertaining the true market value of the land, and of securing that value for the estate in question.

2. The Government has been urged to acquire the land for public purposes, and some intending purchasers have offered to abstain from bidding if the Government would announce its intention of acquiring the land.

The Government has therefore determined not to announce its intention, or to interfere with the sale till the auction is over.

3. The Government has however determined on the acquisition of the land for public purposes, and a formal notice to that effect will duly appear in the *Government Gazette*.

4. I shall be obliged by your causing this decision to be announced by reading this letter at the conclusion of the public sale, in order that the highest bidders who will receive ten per centum on their respective bids may not be put to any further inconvenience or expense.

I shall be further obliged by your furnishing me with the names of the highest bidders for each lot, in order that I may place myself in direct communication with them.—I am, Gentlemen, your obedient servant, H. W. GREEN, Asst. Colonial Secretary.

The following is the result of the sale:—

Lot.	Purchaser.	Extent acres.	Price per acre.	Total.
(1)	Hou, J. J. Grimlinton	162 0 0	R154.32	R25,000
(2)	Hon. J. J. Grimlinton	149 3 0	R153.33	R23,000
(3)	T. B. Campbell	142 0 0	R151.40	R21,500
(4)	K. Macandrew	209 0 0	R150.71	R31,500
Total		662 3 0	R152	R101,000

It was at the close of the sale announced the Government would take up the lots for public purposes; and regarding this a man of business expresses the opinion—"I think the Government have done quite right and that the best way of arriving at the value was a public auction. Government will not be ungenerous to the purchaser. This they have clearly indicated. Had Government said they were going to purchase I don't think they would have obtained the lots for less than R200 per acre."

The following is the advertised description of the property:—"662 acres fine virgin forest in Udapussellawa bounded by St. Leonards, Ragalla, Goatfell, Hsatbersett, Danmark Hill, Gracelyn and Coneygar estates. These blocks of land adjoin each other and are said to contain very fine timber trees. The land itself is very suitable for the cultivation of tea, and owing to the climate, elevation and extensive views obtained from the properties they would make excellent residential estates. Owing

to numerous applications for the above blocks of land, it has been decided to put them up to auction at our sale room, No. 4, Queen's Street, Fort, Colombo, at 3 p. m. on the 18th of May 1891." The property belongs to the estate of the late Mr. C. H. De Soysa.

PLANTING IN PERAK.

The Government of Perak, being desirous of encouraging agriculture in the State, draws attention by circular to the existence of large areas of virgin land available for both hill and low country cultivation, and to the following, among other, advantages which the State holds out to intending planters.

(a) Proximity to Singapore and Penang—two days' steam from the former and six hours from the latter.

(b) The country is traversed by good metalled cart-roads.

(c) Taiping, the capital, is connected with its port, at Port Weld, by a short railway. A railway connecting the Port of Teluk Anson with the inland districts of Batang Padang and Kinta is under construction.

(d) Arrangements have been in force for seven years with the Government of India, admitting of the introduction of indentured Indian labour.

(e) Arabian coffee has given satisfactory results on an estate of about 1,000 acres, opened by Sir Graeme Elphinstone, in the Kuala Kangsa District, while Mr. Heslop Hill's Liberian coffee estate of about 300 acres in the same district is most promising.

(f) Attached is a return showing remarkable crops of Liberian coffee on Messrs. Hill and Rathbours's estates in neighbouring States of the Malay Peninsula.

(g) Tea grown by Government as an experiment, and shipped to England, has been favourably reported on by London brokers.

(h) The Government of the State is carried on under the advice of a British Resident, with a staff of European Officers, and under the supervision of his Excellency the Governor of the Straits Settlements.

The Government is prepared to grant the following special terms to the first ten approved applications who shall apply after this date, that is to say:—Loase or leases in perpetuity for 1,000 acres in one block or in blocks of not less than 500 acres each. No premium; quit-rent 20 cents an acre after two years' free occupation. The Government reserves the right of levying an export duty on produce, which may not exceed 2½ per cent *ad valorem*. If selected with road frontage the depth to be three times the frontage; *bona fide* commencement to open to be made within 13 months from Government approval of selection; cost of demarcation and survey (to be made when required by Government) and registration fees to be borne by lessees. If desired by applications, a premium of \$3 an acre and no quit-rent will be accepted.

Minerals are reserved, and, with the above exceptions, the land would be subject to the general land regulations of the State, which will be forwarded on application to the State Commissioner of Lands, Taiping, to whom all communications in connection with this Circular should be addressed.—*Straits Times.*

CEYLON TEA IN RUSSIA—MR. ROGIVUE'S MISSION—COCONUT BUTTER.

LONDON, May 1,

During the week the Secretary of the Ceylon Association in London has received from Mr. Rogivue copy of a letter just addressed by him to your Planters' Association. From the date of that letter, April 25th, it appears almost certain that it cannot reach Ceylon before this letter of mine should do and I shall not, therefore, be "carrying coals to Newcastle" by just mentioning to you the leading particulars of what your Commissioner in Russia has written, although you will no doubt be supplied with the full text of his letter very shortly after its receipt.

Mr. Rogivue has written much of the difficulties he has experienced and of the obstacles placed in his way by the wholesale tea traders of Russia. To overcome such a disposition popular demand must first be established, and of his success hitherto in doing this Mr. Rogivue does not write very glowingly. Not that his letter is at all despondent. On the contrary, he evidently feels ultimate success to be assured; but he certainly recognises that his will not be a case of "*Veni, vidi, vici.*" He has, he tells us, prepared the ground for a great experiment which he is desirous of making, this being the opening of a kiosk specially for the sale of Ceylon tea, both infused and in packet, at a French Exhibition which is to be opened in Moscow today. Mr. Rogivue writes that he was not aware that specialists would be allowed to retail goods at that Exhibition in time to admit of his seeking authority from your local Tea Committee before incurring expenditure in the direction he has undertaken. On his own responsibility therefore, he has agreed to pay £200 rent for the privilege of selling your teas in a private kiosk to be erected in the grounds of the Exhibition, and he will have also to incur the further expense and responsibility of the construction of the necessary building. For this and contingent expenditure he asks from your Tea Committee a grant of £500, and the details as to his proposal—with which my space will not permit of my entering—seem to justify the confidence with which he makes this application. The Exhibition, it appears from the letter under reference, is assured of a very large number of visitants—estimated at a million—consequent upon the expressed desire of the Tsar that the occasion should be made to express the cordial feelings now existing between his own people and those of France.

Mr. Rogivue's letter further informs us that the draft of £150 (I think that was the amount) which you were recently told by me had gone astray has never reached him. It was enclosed in a letter to him from Mr. Leake which has never yet been traced. However, we learn that the bank has paid the amount notwithstanding the loss of the draft. In addition to the ill-disposition shown by the wholesale trades above referred to, Mr. Rogivue writes that he has to encounter a strong prejudice on the part of the people against your tea, and he has to confess that he has not as yet been able to make his agency pay its way, and has, besides, had to expend large sums in advertising. Among the forms adopted for this latter course he had had large coloured copies of his trade mark—a Sinhalese woman working on a tea estate—posted up and distributed, while large placards have been exhibited calling attention to the superior merits of Ceylon tea. Apparently there are several large houses in St. Petersburg and Moscow which are already considerable importers of your produce, but this is for mixing purposes only. Mr. Rogivue thinks Mr. Popoff's late visit to Ceylon and his proceedings subsequent to that visit will aid greatly in establishing your teas on the Russian market.

He mentions a Mr. Wogall of Mincing Lane, a Russian merchant, as a large purchaser of Ceylon teas in London for shipment to St. Petersburg, and states him to be still buying largely, though only for the purpose abovementioned, that of mixing. Your Commissioner admits that he has still very busy work before him before "crying victory"; but he anticipates marked good result from the six months' course of experience at the forthcoming French Exhibition in Moscow.

We read a good deal in a late issue of the *Key Bulletin* about coconut butter, and a good many

of us wondered to what uses this new material was likely to be put. Evidently these are not to be confined to alimentary purposes only, for it is stated that it is already extensively employed in the making of soap for cleaning metal work. It may probably be a leading ingredient in the well-known Brooks' soap so largely used for that purpose. The soaps ordinarily employed for this are said to be composed of vaseline, oleic acid, and fat, mixed with a little rouge; but they are stated to soon get rancid and worthless, while those soaps of which the base is coconut butter are reported to be wholly free from this liability and can therefore be kept for any length of time. The demand for soap of this character is so enormous, that we can understand now how it was that, according to the *Key Bulletin*, the factories already established for its manufacture were altogether inadequate for meeting the supply required of coconut butter. The knowledge should stimulate your local merchants to some endeavour to enable Ceylon to share in the beneficial results to this demand.—*London Cor.*

GOLDEN TIPS.

The sale of tea from the Havilland estate in Ceylon, mentioned in today's telegram, is the most remarkable yet recorded, the highest price hitherto realised having been over £11. We noticed some time ago in an Indian newspaper an ill-conditioned Indian planter grating out his disapprobation of these high priced sales of Ceylon tea. They were "fancy" prices; there were scores of tea gardens in India which could do the same thing if they chose; only Anglo-Indian managers were far too sensible to spoil a whole flush, plundering its golden tips for the sake of one unique parcel. No doubt £17 per pound is a fancy price, and possibly the value of a portion of one season's yield on the Havilland estate may have been impaired for the sake of this one parcel; but what then? The Ceylon planter, his Indian critic may rest assured, is not an ass; and if he sacrifices something to make a show in Mincing Lane, he does it with the knowledge that the advertisement will pay in the end. His appreciation of the value of a good advertisement, his energy and resource in pushing his wares, have had this result, that Ceylon tea in ten years has become rather better known all over the world than has Indian in forty. There is another conso beside the literal in which the parcel from Havilland might be said to contain "golden tips."—*Pioneer*, May 8th.

TEA CONSUMPTION AND DUTY.—With the completion of the tea returns for the port of London for the past month we are able to see what effect the reduction of the duty has had on the trade since it came into operation a twelvemonth ago. The imports show the extensive increase of 13,985,949 lb. as compared with last year's figures, the total quantity imported being 147,863,040 lb., against 133,877,091 lb. last year. This increase is almost entirely in Ceylon tea, the production of which is increasing very rapidly in consequence of the favour which the public have shown towards it.—*L. and C. Express.*

THE AMSTERDAM QUININE WORKS.—The annual general meeting of the shareholders in these works took place on April 30th, Dr. J. E. de Vrijin in the chair. The directors' report shows that although sufficient profit was made during the year to provide for the amount which, according to the statutes of the company, must be written off annually, yet no dividend could be distributed. The output of the factory in 1890 amounted to about 350,000 oz. (9,952 kilos.) sulphate of quinine, and the sales to about 300,000 oz. (8,628 kilos.)—*Chemist and Druggist.*

PROSPECTS OF CEYLON TEA.

The figures forwarded by Messrs. Gow, Wilson & Stanton are encouraging, as far as delivery is, in Britain are concerned. For the 11 months of season 1890-91 ended 30th April, the deliveries were 38,000,000 lb.* out of an import of 42,225,000. The increase over the quantity delivered in the corresponding period of the previous season, (26,927,000 lb.) was no less than 11,000,000 lb. The increase in Indian tea in this season over the past (93,924,000 lb. against 86,675,000) was only 9,249,000; so that comparatively as well as absolutely, the deliveries of Ceylon tea have largely increased,—as yet in proportion, indeed, to rapidly increasing crops. Making all allowance for efforts made by the producers to bring their product into notice, nothing but the real superiority of Ceylon tea could have placed it in such a position. The question is, however, whether over-production is not already casting its dark shadow before, in the sharp and sudden fall in prices reported from London. Our unceasing efforts ought to be directed to the opening up of new markets and also the conquering of old markets where hitherto the teas of China and Japan have reigned supreme. The better, and, considering its quality, the cheaper Ceylon leaf will have to contend in the United States not only with the prejudice of tea drinkers, born of custom and acquired taste, but with a stagnant and even decadent demand for tea, not only as compared with coffee, but also, to our exceeding surprise, considering all we have heard of temperance and even prohibition movements in the United States, with the enormously increasing taste for alcoholic drinks. The figures we quoted from the *American Grocer* in our issue of the 16th, were certainly not reassuring to the friends of temperance and non-alcoholic beverages. The decrease in the consumption of coffee from 9.45 lb. per caput, in 1885, to 7.90 in 1890, is attributed to a rise in the price, due no doubt to deficiency in production in Brazil, owing to emancipation and revolutionary troubles. But no such cause can be adduced for the discouraging position of tea. Not only has the consumption not increased in the decade between 1881 and 1890, but there was an absolute decrease from a miserable 1.54 lb. per head of the population in 1881, to a still more miserable 1.34 in 1890. The retail cost of the tea consumed in the United States in 1890 (all save mere fractions of Indian and Ceylon, the produce of China and Japan) was only \$30,000,000 (less than half a dollar per head) against \$122,500,000 for coffee (over two dollars per head). But to those who, like ourselves, believed, and rejoiced to believe, that the cause of temperance in the United States had made such progress as to justify the existence not only of a "High License" but of a "Prohibition" party, the disappointment is keen as it is astounding to learn that while the consumption of tea and coffee is stationary or decadent, at a united value of only \$152,500,000, the value of alcoholic drinks consumed had increased \$200,000,000 in four years (at the rate of \$50,000,000 per annum) up to the astounding total for 1890 of \$900,000,000! This is at the rate of more than fourteen dollars for every man, woman and child in the States. In view of such facts, and of the difficulties which have gathered round the production of coffee, we feel that, apart from questions of self-interest as regards our own Ceylon tea, all friends of temperance and human well-being ought to wish "God speed" to all judicious and legitimate efforts to introduce India and Ceylon tea to the markets and

* At the rate of about 42,000,000 lb. for the 12 months.

into the homes of the United States. We say advisedly "judicious and legitimate," because we can see no prospect of good but rather of harm to the cause of Ceylon tea in the wild scheme, wrong in principle if even it were practicable, of "cornering," that is monopolizing a market which above all things needs to be opened. Our object ought to be to conciliate instead of irritating dealers and consumers of tea; and therefore, while we urge more strenuous efforts than ever at opening the markets of the United States for our teas, we regret more than we can express that the leader of the Company formed for this purpose, should advocate the adoption of measures which are calculated only to injure instead of furthering the interests of Ceylon tea and tea planters. Nothing can in the end be successful, which is opposed to the foundation principles of free, open, legitimate competition, the very life of a righteous commerce. To indicate in any way that we are not prepared for a fair field and no favour, save what desert will secure, would be fatal to the claims of our really superior product. That quality will secure its share, if at first comparatively slow, success, while all attempts at "cornering" explode into vapour.

A VISIT TO THE COLOMBO IRONWORKS.

"As a descriptive title 'Colombo Ironworks' fails to convey an adequate idea of the nature and extent of the operations conducted by Messrs. Walker Sons & Co., Limited." That is the observation of one who recently paid what he calls a "flying visit" to the works. He does not mean to suggest that there should be any further change in nomenclature, but merely to emphasize, the fact that he was surprised to find that the business was so comprehensive. He had heard that the firm did a vast amount of work for planters, and knew that they were the agents for W. & J. Jackson's Patent Tea Machinery, but his knowledge was limited to these facts; and he was therefore much astonished to see that in addition to the manufacture and repair of all the kinds of machines in use in Ceylon, considerable orders were executed in connection with the construction and renovation of buildings and of vessels. The appliances, he says, are of the latest and most approved pattern, some of them being specialities for patents of a very interesting character. Competent and experienced Europeans are in charge of the various departments, and the native subordinates are really excellent workmen.

Another thing which seems to have struck the visitor is the order which prevails in the establishment. Everything, he says, is done according to a clearly defined plan; and the result of this methodical mode of working is that a degree of smoothness is attained in carrying out all the arrangements that must enable the firm to undertake very large contracts and satisfactorily accomplish them in the shortest possible space of time.

The premises may be said to consist of three main buildings, one being the fitting or machinery shop, another the smithy, and the third the foundry. Passing through a yard where a water-wheel, 25 feet in diameter, and some steel barges were in course of construction,—the former for an upcountry tea factory and the latter for the Wharf and Warehouse Company,—the visitor entered the fitting shop on the left, and looking along a series of courts or divisions saw quite an army of native mechanics busily employed at lathes of various sizes turning

shafts, bolts, pulleys, &c., planing, slotting and shearing machines, vertical and circular saws, and other machinery all driven by steam. A large radial drilling machine attracted the visitor's attention. This machine is used largely in connection with the manufacture of Jackson's smaller tea rollers. The piece of machinery to be operated upon being once properly laid on the table there is no necessity for moving it in the slightest (although the casting may require boring at different points) until the work of boring has been accomplished, for the drill has a swinging arm in which there is a slide from which the borer depends so that in the language of the engineer, it is "quite true" in its work. "To the reflective mind," philosophically, adds our correspondent, "there is much food for thought in this characteristic of a simple piece of mechanism, and the moral lesson it teaches cannot be too often repeated." Of the variety of saws he makes special mention of one which he says must very considerably facilitate the work in the carpentering department inasmuch as it has an arrangement of blades by which it can cut up a log of wood into a large number of planks at once. After watching for a short time workmen engaged in the actual fitting up of machines the visitor proceeded to the upper storey of the building, where on one side he found men at work on the famous tea rollers and the patent pulpers of which the firm has turned out thousands and is still executing orders, but principally for Java, there being practically no demand for them now in Ceylon since the failure of coffee. On the other side of the building carpenters were busily preparing wood for structural purposes and fashioning it into doors, window-frames, &c. Amongst the apparatus there considered worthy of some notice was a planing machine which did its work not only expeditiously but with remarkable efficiency, the wood coming out so smooth that it had a polished surface. A band saw was also closely examined, and the fancy work it accomplished evoked admiration. Going downstairs noticing in passing that water buckets were suspended throughout the building so that any outbreak of fire—a remote contingency but still one which requires to be guarded against—should be promptly dealt with, the visitor crossed the intervening yard, where he saw the water-wheel and barges being built, to the blacksmiths' shop fitted up with a number of fires fanned by currents of air passed through pipes from a steam-driven fan in a small engine-room adjoining; two siren hammers which can be regulated so as to come down almost as lightly as corking machines or with tremendous crushing force when required, several large drills and shearing and punching machines. It was an interesting sight to see the native smiths at work. They wielded the hammer with a strength and skill which licked the red hot iron, into shape as if it were of the consistency of putty rather than of metal. Scarcely clothed as they were, they fearlessly attacked the glowing iron and seemed perfectly heedless of the flying sparks. The foundry was next inspected. It is situated farther along Prince Street beyond the coal-sheds, and unlike the other buildings has been entirely constructed by the Messrs. Walker. It was in the morning when our correspondent visited the place, and he had not the opportunity therefore of seeing any cast, but he saw all the appliances and had the process clearly explained to him by the superintendent, an intelligent, hard-working Scotchman. He saw a large number of pillars being prepared, and these he was told were intended to be used in the extension of the Grand Oriental Hotel. In addition to the crane outside for lifting the

raw material to the cupolas down which it is tilted into the furnace, there are three others inside used for conveying the vessels containing the molten metal to the moulds. Large quantities of old metal are remelted, and the visitor was much interested to observe that amongst the material to be used for this purpose were piles of cannon balls and as many big guns as would suffice for the equipment of a tolerably sized fortification. The ordnance he believes had been in use at Trincomalee, and it will now undergo a process similar to that which is implied in the conversion of "swords into ploughshares," being diverted from destructive to constructive purposes. The guns are broken by means of a heavy ball of iron called "Jumbo" being raised to a height and then suddenly dropped upon them, and the fragments are then put into the cupola as required. Leaving the moulding shop, the marine work being executed by the firm was inspected; and our correspondent says he was quite astonished to find so many vessels whose repair had been undertaken by the firm. He noticed that the hopper barge "Industry" had just left the slip, and was informed that it had been practically replaced from stem to stern. On the slip there was a steam launch having a saloon deck; and on enquiry the fact was elicited that the vessel belongs to Mr. Akbar. It is being fitted with new engines, and from the shallowness of its draught appears to be admirably adapted for river navigation. The slip it should be mentioned is 300 feet in length and is capable of taking up a vessel of 100 to 120 tons. Amongst the other vessels noticed by the visitor was a steam launch being built for the British India Co.; and he could not help admiring its graceful lines. Salvage operations also form an important part of the firm's business, and the establishment is thoroughly equipped with all the requisite apparatus for this difficult and often dangerous work—a huge coffer dam, salvage pumps mounted and ready for action, and diving gear. Altogether our correspondent says he was greatly pleased with his visit to the works, and concludes by expressing his best wishes for the success of the firm under its new name.

TEA PLANTING IN NATAL.

(By an ex-Natal Tea Planter.)

SITES FOR PLANTER'S HOUSE—TEA PLANTING A SUCCESS IN NATAL—SOIL—CLIMATE—NURSERIES—PLANTING AND PICKING—MANURING AND DIGGING—SHELTER TREES—LABOUR SUPPLY—PREPARATION OF TEA—INSUFFICIENT TRANSPORT FACILITIES—CEYLON TEA IN NATAL.

The site which the Natal tea planter chooses for his home is one of a somewhat elevated position as the great importance of fresh and pure air has become fully recognized. Extended views of landscape are usually selected, for the front or principal outlook; and as these already exist in Natal, the site of the hall or castle is settled, where natural beauty exhibits itself; no other place is selected.

Tea is admirably adapted to the climate of South Africa. My stay there was for two years and was on an estate of 4,500 to 5,000 acres, three hundred of which were planted with tea. I found that tea likes a damp, warm and genial atmosphere. Heat and moisture seem to be the two things which make the thing a success. It is necessary also to screen the tea from rough and cold winds; and if treated fairly well, it will give good returns and good flushes, and will cause the planter to smile when he pnts his hands into his pockets. The soil in Natal is of a rich, yellow loamy nature, inclining to be sandy, it is not hard and lumpy, but loose, and this causes the roots of the tea to run easily, and find their beds. It is a great thing to see that the plants are put in carefully; if

they are huddled and squeezed in anyhow, it often causes a lot of undue and useless shoots to appear, which greatly damage the growth of the tree. Seeds just sprouted are sometimes put into the hole to the number of from three to five, and if all come up, they are easily lifted and planted elsewhere. In one season they will have pushed through their shading to the height of 1 foot to two feet. This shading is generally branches from trees, from grass, or from the wild date palms of Natal (*Phoenix reclinata* or *Phoenix spinosa*). After the trees become large, so that they can stand alone, this covering is removed, and the trees grow sturdy and strong.

The rainy season, or the good season, as it is called, commences in October, and it makes all hands busy, with planting and picking. The preparation of the ground is done in the winter months; the jungle or "bush" as it is called in Africa is taken down, and all weeds and rubbish are burnt, the land is turned over and holed, ready for the time when the rains come. A coolie will make two hundred to three hundred holes per day. The plan adopted in laying out is to get as long lines as it is possible to be had; tea is generally planted four feet by three, but sometimes six feet by five and a half. If we could get our tea out in the early months of the rainy season, it paid us well, and whatever expenses were laid out in labour and attention, in the first or second year, in the third we recovered all expenses. I have seen tea bushes three, ten and twelve feet across, with a heavy flush; a man will bring in from twenty-five to fifty lb. of leaf per day, if there is a good flush. Pruning operations are done in the month of July, always cutting hard into the centre of the tree so as to leave the tree shallow basin shaped. Manuring and digging are done in the months of August and September, and any spare time is spent in taking down bush and cleaning land. Seeds are gathered in the month of March, which is the dry season and put into nursery beds, and by the end of September or October are quite ready for planting out in lines; these lines are kept free of weeds so as to give the tea every possible chance. Very little draining is done excepting in places where there is standing water or in places where there is likely to be a flood.

A most important thing in the successful growing of the tea in Natal is shelter. I find that with having shelter the trees are stronger and are better able to yield a good flush. Shelter is best afforded by trees of a quick-growing nature and such as are known to succeed well in that locality. Hot and cold winds have to be provided against as sometimes the winds are so hot, that together with the heat of the sun they scorch the leaves; they are particularly hurtful to the young flush. The gum (*Eucalyptus*) does well in Natal, growing to the height of twenty feet in three years. *Pinus insignis*, *P. pinca*, *Pinus pinaster* and *Grevillea robusta* also do well; in fact any tree of an ornamental character is suitable to break wind, besides acting as a screen against rough blasts they produce a most pleasing effect. Lines of fancy trees and shrubs wherever planted will protect the young and tender shoots of tea by neutralizing the force of the wind and rendering its effects on tender shoots less dangerous. Tea planted within thirty feet of the gum will not grow well. In order to let the tea have fair play, even at this distance, trenches are dug seven or eight feet from the gum, to the depth of two or three feet which cause the roots to seek a lower bed.

All the work is done by Indians from Madras and Calcutta, who come out under a five years' agreement; when that is finished they are free men, they are at liberty to stay or engage elsewhere, for another term. If they stay ten years in Natal, the Government pay their passage back again, if just for one term only, they must pay their own passage. The women get 5s per month, the men from 10s to 15s with the allowance of 1½ lb. of rice per day, together with fish, oil, dal, salt. They are allowed to build their own houses in a stated time, wood and grass being within easy reach. They work from sunrise to sunset. They are called to and from work by means of the estate bell, which is rung at certain times. They are capital workpeople, when well looked after. They are generally intelligent

and industrious. The tea is made by means of machinery, the work being done by boys in the factory, who do well. The only thing which is a drawback is lack of means of transport, railways are not numerous as yet; as in other colonies bullock waggons are much used, sixteen or eighteen going to the span. Indian and Ceylon teas are sold in the colony at lower prices than the home-grown tea, and this will probably cause the Natal teas to decrease in price, and will consequently bring a smaller return to the planter, who up to the present has realized very good average prices. None of the tea has yet been exported, and as the total acreage under cultivation is under five thousand acres, no doubt it will all continue to find a sale in the colony itself.

W. M.

CEYLON TEA IN AMERICA.

From a letter of Mr. Pineo, dated New York, 10th April, we quote as follows:—

"You in Ceylon may think we are not ordering tea very fast, and we are not, although I shall, I think, call this week for 15,000 lb.; and yet we are working for results in a sure and, hitherto, untried way. We are not having the tea piled, and laid away on grocers' shelves, but we are getting it direct into the households. That is what we are working for now—so that, by-and-by, the grocer will be obliged to come to us and will sell and not pigeon-hole and after awhile return our tea to us as unsaleable, undesirable stuff.

"Our Chicago agent has induced the proprietor of the 'McCormick' building to change the name and it is now known as the 'Ceylon' building; hence you will understand we are quietly, slowly, surely sowing seed in good ground that we are in the first instance, thoroughly preparing. We look for substantial, permanent, lasting results, and are not working to make an immense showing at first, and then disappearing and vacating the field and thus injuring the cause we are so earnestly working for.

"We have made arrangements with a gentleman here who is believed to have large means to make up the retail selling of our brands of tea for New York City and suburbs. He has taken a splendid store, on West 23rd Street, near the great retail establishments of Stern Bros. and LaBoutillier Bros. who ladies flock daily by the thousand, and he takes the native servants and all the expense of this matter upon himself, as well as investing a fair amount in the Company's stock.

"This relieves the Company of a very large expense and what is still better, gives us a good worker.

"Maillard is the fashionable dealer in cocoa, etc., and is known as such all over the United States."

COAL IN PUSSELAWA.—Some time ago we had a paragraph stating that a mineral resembling coal had been found on Rothschild estate, Pusselawa and that Mr. LeMesurier, A. G. A., hearing of it, had taken the matter up and had induced the Government to send a sample of the find to Mr. Geo. Armitage. This gentleman found the lumps sent him to be real coal, but could not say whether it would pay to carry out prospecting operations in the neighbourhood of the find till a proper survey had been made on the spot. Government sent him Mr. Armitage's report to an expert in England and that is as far as Government has yet gone in the matter, but we hear that Mr. LeMesurier, when he went to England recently, took home a couple of cigar boxes filled with lumps of Ceylon coal for a further report on their quality and value. Since the first find on Rothschild, it has been discovered that the seam of coal there can be traced again on the opposite side of the valley, and we trust that the matter, which is of great scientific as well as commercial importance, will not be allowed to rest where it is at present.—"Local Times."

CEYLON TEA FOR AMERICA.

A private letter from London conveys to us, what is deemed rather more re-assuring intelligence in reference to Mr. Elwood May's attitude and aspirations. The idea of establishing a vast "corner" or monopoly in Ceylon tea had evidently been dissipated by contact with "City" men doing business in "tea," and instead he was likely to make proposals which were much more practicable and indeed commendable. In the first place Mr. May has made it clear that the great difficulty encountered by the Company of which he is President, in bringing Ceylon tea into universal use in America, arises from the widespread manipulation and adulteration of inferior teas. There is no law, it is alleged, in the United States, as in England, against adulteration; and the multitude everywhere run after a cheap article unless their attention is specially arrested after a striking fashion—and the more striking and startling the better on the American continent. Now, so far as they have gone, the Ceylon Planters' Company—or rather the New York Directors—have done exceedingly well in securing first-class agents in several of the principal eastern towns and in Canada; and it is clear that through the influence of these a large and growing business is likely to be transacted. But as regards the central and western divisions and the country at large, Mr. May thinks that the Company should have more significant and impressive credentials from the tea planters of this colony,—a formal "endorsement" in the term he uses—to bring home to the American public mind that the Company is, above all things, the representative and vendor of pure Ceylon tea throughout the Far Western Continent. This, *per se*, is not altogether an unreasonable wish or request, if the main object be to fight the trade in cheap low class or adulterated stuff. How the "endorsement" can be given effect to by the planters, independently or through their Association, it is not so easy to see; but probably some practical suggestion may arise out of the conference which Mr. Elwood May was to have with the Tea Committee of the London Association. It is intimated that Mr. H. K. Rutherford, in anticipation of that Conference, had prepared a scheme to enable the Ceylon planters to utilize the Company as their special agents at the Chicago Exhibition. That is a very good suggestion indeed, and we trust to see it worked out after a practical fashion. But it scarcely covers the position taken up by Mr. May in reference to the Continent at large. One reason why more explicit representative credentials are required is said to be to satisfy some powerful American capitalists who are inclined to take shares and join the Board. If it is clearly understood from the outset that the Company is only to deal in Ceylon teas,—to sell nothing but *pure Ceylon teas*—to challenge to this end, analysis or examination of any of its packets or chests as sold all over America,—then indeed the Directors deserve very handsome treatment from this Colony, and its planters especially, and scarcely any resolution that could be passed by the Tea Fund Committee or Planters' Association should be deemed too strong for the occasion. We must remember that a form of words which might be deemed by us in England to be absurdly grandiloquent and out of place is not so "reckoned" among the sixty millions more or less who constitute the mighty Republic across the Atlantic. These are, in substance, the statements which have reached us. Meantime, however, we have to see what the Conference with the Tea Committee in London may bring forth.

THE PLANTING EXPEDITION TO PERU.

Messrs. Sinclair and Ross were to have left Liverpool for New York on 20th May. After a brief stay in the States, they expect to visit some of the West India islands—perhaps look in on the Jamaica Exhibition—before going on via Panama. Mr. A. Ross has, we understand, been very busy in preparation for the Expedition; in fact much of the organizing has been left in his hands, and he has besides been qualifying himself after a characteristic fashion, shewing all the buoyant energy of the typical Ceylon planter. Mr. Ross has been taking lessons in navigation, &c., so as to be able to take observations, and he has also qualified as an amateur photographer. His experience as a cacao planter in North Malacca will also stand the Expedition in good stead, while the relations between the three Ceylon members—Messrs. Sinclair, Ross and Clark—are certain to be marked by the utmost cordiality and confidence. If the Peruvians give the support faithfully promised by them, the Expedition cannot fail of a large measure of success in making known the character and capabilities of an immense expanse of new country. All three gentlemen have stood the test of a very strict medical examination.

TEA SALES AT HOME AND PROSPECTS.

A Planter writes on 20th May:—This is my news from home by mail of May 13:—"Ceylon Teas are coming in faster than the market can stand, and prices have been irregular and weak at this week's sale. Indian teas are also less price, although it is estimated that only 50,000 packages remain to be sold for the season. China congou has been pressed for sale at auction and the low prices now current for good quality will check heavy buying in China for England at the commencement of the new season."—It is thus clear that our having begun heavy exporting in the beginning of the season has choked off China. I do not think our heavy exports are all due to favourable weather but coarser plucking, estates that used to give from 100-200 lb. per acre are now yielding 400 to 500."

COCONUTS AND CINNAMON.

KADIRANA, May 15th.—No monsoon as yet here, and the hills are still very distinct every morning and almost throughout the day, showing that there has not been very much rain in their vicinity. Very little rain since the 20th April. On the 12th instant there was a good shower measuring 1.63 inch, and the total to date is only 2.01 inches, which is unusually little for this time of the year. April also was very short, the total being only 3.50 inches. The fall for the first 4 months of the year is 19.43 inches, which is about the average of the four previous years; such a dry April and May however is unusual. It is to be hoped that the latter part of this month will show an improvement. Fever is very prevalent since March: April and May being very bad. Though not so serious as it was in 1887, it is very much more prevalent than usual about this time; and on estates and in the villages there is hardly a house without one or more inmates ill. This is the time when, in addition to treatment at outdoor dispensaries, there should be itinerating medical officers going through the villages. Dispensaries are generally 10 to 12 miles apart, and though those living within 2 miles or so will avail themselves of them, it is hardly to be expected that those further away will patronize them. It is in these cases that itinerating medical officers could do so much good, by preventing needless suffering, and saving many lives. Fever is the bane of Ceylon, and to it mainly, in my opinion, must be attributed

the small increase in the population of so many districts of the Island during the last decade.

A bud is showing on the cinnamon bushes which may possibly necessitate a stoppage of peeling operations for a time. The effects of last year's drought are now showing in the small size of the nuts being gathered; some are ridiculously small, and all below the average. This state of things will continue I fancy till towards the close of the year.

Surely there must be a large number of barren or male coconut trees in the Windward Islands that makes Mr. Huggins seem so anxious for a remedy? These are so rare in Ceylon (perhaps not one in three or four thousand) that they are not worth considering; the same may be said of trees that produce nuts without kernels. I am not sufficiently acquainted with physiology to be able to explain these freaks of nature. Mr. Huggins wishes to know whether such trees cannot be grafted with fruitful ones. Is it possible to graft on mono-cotyledonous plants?

Kaïraua, May 17th.—Grand rain last night; measured this morning 5·87 inches. The rain fell quietly and steadily all night. No wind, lightning or thunder.

INDIAN AGRICULTURE IN ITS PHYSICAL ASPECTS.

Dr. Veeler has published the following paper:—
To anyone interested in agriculture a tour in another country, even his own, is not to be of much profit, and when that enters a special and definite study of the agriculture of a distant part of the great British Empire, it is surrounded with peculiar interest. Already the growth of an export trade in agricultural produce from India has exercised a considerable bearing upon England itself, and the condition of that vast country with its teeming masses, the greater number by far engaged in the pursuit of agriculture, cannot fail to be a matter of deep concern. Looked at purely from the point of view of an agricultural observer and inquirer, I can hardly imagine any field so fertile in rewarding a careful study as India offers; and when one is privileged, as I have been, to pursue an investigation under auspices so favourable and with advantages so great as were afforded to myself, he can scarcely fail to return deeply impressed with the general excellence of the native agriculture of India, and with the truly wonderful administration of that great and important Empire.

The first and most natural differences that strike the newly-arrived visitor are the prevailing heat and the ever-present sun, features playing a most important part in determining the agriculture of India. As the journey is made from Bombay or other seaport into the open country, the town is rapidly left, and many an hour or even a whole day may be passed in the train before another town of any considerable size is met with, for agriculture is the staple industry and occupation of the people. But in place of the wide and often undulating fields of England, the monotony of crop-growing pleasantly broken here and there by the variation of pasture land with its feeding herds of cattle and sheep, we find in India a level plain stretching for many miles along our route, and split up into almost minute divisions, upon which not one but several crops or patches of crops may be seen growing. No hedges nor even stone walls mark the boundaries either of field or holding, for, in all but a few special districts, hedges, properly so called, will not grow, and in other parts one may traverse a thousand miles without coming across a stone even the size of a pebble.

It is not a land of large, but of very small

holdings, the average area belonging to a cultivating tenant being only about five acres. On this small space he and his family, and often his brothers or other relatives with their families as well, exist—living, as it were, under a communal system. No trees surround the fields or break the landscape, unless where a poor and barren stretch will not repay cultivation, and has been left to jungle growth or remains a bare parched spot. Along the coast may be seen dotted here and there the tall coconut tree; but its region is soon left behind and an occasional *palmyra*, or *toddy-palm*, takes its place. It is only when the journey, it may be of several days' length, brings one to the mountain or hilly regions that the vast forests are met with and fringe the cultivated area; otherwise, the general appearance of the country is that of a vast, heated, and apart from the agriculturist, uninteresting plain.

The workers we see on these small five-acre holdings are not the day labourers, with the farmer walking busily amongst them but the tenant himself and his family, each taking his and her part, and more frequently than not working on rather than *above* the ground—a group of scantily clad dusky men and women, here equating down and busily weeding; here, in a similar position, outing a crop with hand and sickle, and laying the hand-fel side by side until a bundle is gradually formed; there driving along the pair or more of oxen (not horses) that pull the plough which lightly runs through the top surface of the soil but turns no furrow over; there throwing with wicker basket-scops the water from an adjacent pool or running channel on to the growing crop, or raising it from a well in leathern buckets drawn up by bullocks with a rope and pulley. In place of grazing herds in green fields, there are wandering troops of thin half-starved cattle that roam, over the barren tracks, picking up what they can, though hardly a green spot seems to reward their search, or goats that pull down and pluck every green bough or twig that offers itself, or buffaloes cooling their hides in muddy pools, from which if possible they will allow only their heads to emerge.

As we pass on, other changes are noticed: what is now in the cold season a tiny stream, and in the hot season may be dried up altogether, will in the rainy period swell into a vast swift-flowing torrent, and cover the wide bed which now lies exposed. Elsewhere a canal, or its numerous branches, carried off by engineering skill from some great river, brings the all-essential water that the crops require, and without which agriculture would in many parts be at a standstill for the greater portion of the year. Yet another feature cannot fail to strike the eye; in some districts are vast plains coated with a snow-like crust and devoid of all vegetation. These are the well-known *reh* or *usar* tracts, the bringing of which into cultivation has baffled nearly every effort, but the reclamation of which would, over many thousand acres, supply food for the wants of an ever-pressing population.

As the days and the weeks go by we have no longer the changes of a fickle English climate with its alternation of rain and sunshine, but a steady continuance of a long series of days one like the other, but always hot; then, as March is reached, it becomes hotter and hotter, until when all the country presents at length a burnt-up appearance, there comes, about the end of June or early in July, a tremendous change. The rains descend in torrents, the rivers become swollen and flood the land, and coat the barren spots, as if by magic, with a green sward.

Such are, very briefly, some of the most prominent features that characterise the external appearance of Indian agriculture. But this, though

a sketch of what may be seen, is not true by any means of all parts generally; for I may as well say at the outset that there is hardly a statement that can be made about Indian agriculture, as deduced from any one district, which cannot be met by a precisely opposite statement taken from the experience of another. It has been well said that there is no such thing as *one* country India, or *one* Indian people. It is a continent fifteen times the extent of the whole British Isles, and made up of many countries and many peoples, all totally diverse. So also is it with regard to the agriculture: and in this consisted the very difficulty I had to meet—the impossibility of suggesting any general improvement which might be applicable to many parts alike. Each portion of the country must be taken by itself, and in relation to its particular surroundings and circumstances. What those were, it was my duty to ascertain and now briefly to describe.

With the above caution I would say generally that the agriculture of India is, in my opinion, excellent; and how to improve it is a problem which is, I do not hesitate to say, a harder one than how to improve English agriculture. More than this, I have seen numerous instances of as fine and careful cultivation, combined with fertility of resources on the part of the raiyat, or cultivating tenant, as is to be met with in the best parts of our own country. The determining factor with the Indian cultivator is the facilities to which he has access. The excellence of his cultivation is bounded not by the use he makes of the facilities; indeed, it is wonderful how he does utilise what he has. Nor is it bounded by his want of knowledge, but by the existence or non-existence of the essential requisites to success. I, therefore, unhesitatingly dispose of the ideas which have been erroneously entertained that the raiyat's cultivation is primitive and backward, and say that nearly all the attempts made in the past to teach him have failed, because he understands far better than his would-be teachers the particular circumstances under which he has to pursue his calling.

To take first the people, or rather the peoples. Agriculture is, as I have said, the main occupation of the country, and it is estimated that fully 90 per cent. of the rural population is directly engaged in its pursuit. Of the 265 millions that inhabit India, there are about 145 million Hindus, and among these, generally, the best cultivators are found. The 45 million Mohammedans are scattered among the Hindus, preponderating in some districts and being fewer in others. They are a meat-eating race, as distinguished from the Hindus, who, as a rule, are not. Large herds and flocks are therefore in the care of Mohammedans mainly, and they are also the butchers; among the Hindus, however, are several tribes and castes whose associations are with cattle, though for the most part with milking and breeding herds. Along the river sides the Mohammedans predominate, and thither and into the forest the plough and the milking cattle are driven in the height of the hot season.

Along with the rainfall, the soil must be taken as determining also to a large extent the nature of the crops grown. Broadly speaking, India may be considered as divided into three distinct geological series; the first or northern portion, which is one vast alluvial area and comprises the great Indo-Gangetic plain; the second, a central zone spreading over part of Bombay, Central India and the Central Provinces, the soil being known as the black cotton-soil; and, thirdly, a rocky area comprising Madras and Southern India generally. Each division has its minor local distinctions; but while of the northern it may be said that it is a rich alluvium, quickly drying and needing replenishment by rain or irrigation from well or canal, the black cotton-

soil is very retentive and holds ample moisture from the annual rainfall, so that artificial irrigation is hardly, if at all, required. In the third or rocky one the only way to provide water is by storage tanks or by channels led from rivers or streams, irrigation from wells being difficult. Thus, in the north may be seen regularly on the same holding the crops of both seasons, the one growing by the aid of well or canal irrigation, the other by means of the rainfall and the powerful heat. In the Central Provinces, on the contrary, are great stretches of cultivation, of one and the same kind, in some districts the cold season wheat and linseed, in others the rainy season cotton and millets; whilst in Southern India, as explained, the crops go on much the same all the year round, and are distinguished mainly by early and late sowings.

Over individual areas, again, there will be enormous variations in the amount of rain fall, each having its correspondence in the crops grown and the method of cultivation pursued. Thus, crops which depend on heavy rainfall and a damp climate flourish only in certain parts—Assam, for instance, with its rainfall of from 60 to 160 inches and more, produces tea luxuriantly; Bihar gives the indigo cultivation; and rice belongs to Burma, Eastern Bengal and the western coasts of Bombay. Other crops, such as wheat, require a drier climate, though water may in some cases have to be given artificially; others again, such as the pulse crops, *gram* (*Cicer arietinum*) or arhar (*Cajanus indicus*), can, when once germinated, do without dependence on water, and are suited to a hot, dry climate. The indigo plant, again, is favoured in the development of leaf (the portion used for making the well-known dye) by the damp climate of Bihar and Bengal; but the production of the root gives much better in the drier climate of the Punjab and the North-West Provinces; and so it is that the two cultivations are carried on in quite distinct parts of the country.

Nor is the influence of varying climate seen alone in the crops, but it is marked in the cattle and even in the people themselves. On the dry plains of the Punjab especially, and also in the North-West Provinces, the bullocks are fine, large and strong; but when we come to the damp regions of Bengal they are found to be diminutive and miserable looking. Buffaloes, however, rejoice in a wet or damp climate, and they flourish in many parts of Bengal and along the Western Ghats, taking frequently the place of bullocks as plough cattle. The Bengali, clever as he is intellectually, is a poor specimen physically, when put by the side of a Sikh from the Punjab, or even a North West raiyat.

The bearing of an uncertain rainfall on the possibility of famine, and the determining of means to prevent it, are most important points. It is neither in the wettest nor, singular as it may appear, in the driest tracts, that there is the greatest danger of famine. In the former, as also on the moisture-holding black cotton-soil, there is always certainty of sufficient water; in the driest tracts, again, the raiyat will never venture on growing a crop unless he is certain of having water enough. But the really precarious districts are those in which there is just this chance of enough rain coming to induce the cultivator to venture on sowing a crop; for, should the rain not come or not continue, there will be a total failure of the crop, and scarcity will result. If this be followed by a second failure, what is known as famine will set in. Happily, the Government have wisely foreseen that it is these precarious tracts which most need the extension to them of means of irrigation; and happily, too, the expansion of the railway system enables the quick transmission of stores of grain

What, however, is still to fear, is, first, that a famine may come in any part before even the authorities are aware of it, for they are so few and so widely scattered, while the people themselves will never complain, but bear their misfortunes in silence; secondly, the simultaneous occurrence of famine in different regions, for, there being no stored reserves of grain in the country, it is only possible to imagine how direful in its effects such a calamity must of necessity be.

Next to people and climate, a word more must be said about the soil than has already been included. But little is known about it beyond what the cultivator himself knows practically. The main geological types are few, but the local subdivisions are many, and for each of these the *raiya*t has his particular name, and the knowledge of what it will best produce. There are no peaty soils, nor anything akin to our gravels, colts or chalk soils, nor yet to our heavy clays, but there are the vast plains of alluvium already referred to, the singular black cotton soil, and subsoils composed of a concretionary kind of limestone known as *kankar*. Classification of the soil according to its capabilities is the system on which assessment of the land revenue (for the Government is practically in the position of landlord) is based, and this is modified according to the various local circumstances, the facilities for irrigation, etc. In a country where irrigation plays so important a part, the relation of soil to moisture is necessarily one of the greatest moment. It is true that in some parts the superfluous water has to be led off the land, but this is done by carrying it in channels or by a system of embankments which prevent the rush of water over the surface, and the consequent washing away of the top soil; it is not done by any subsoil drainage system, so familiar to us in this country.

But the main problem in India is not how to remove the water, but how to bring it to the soil, and then how to keep it there. Indian soils are normally dry, English soils wet.

The mention of this naturally leads one to consider whether the native system of shallow-ploughing, or rather *scratching* the ground, is so very wrong as would be improvers have made it out to be.

The action of the native plough resembles that of a pointed stick running just below the surface of the ground, some 2½ to 3 inches deep, and stirring the soil whilst it tears out and brings to the surface any infesting weed. Though there may be instances where deep-ploughing would be effectual, I believe that in the great majority of cases the native system of ploughing is the one best adapted to the conditions, and that, were a furrow-turning plough used, the result would be to lose a great deal of the precious moisture. Again, if the soil be at all stiff, the slice turned up by an English plough would speedily become baked in the hot sun and remain a brick rather than soil. The native ploughing, on the contrary, pulverise the soil, and repeated going over the land, while it costs the cultivator more (for the bullocks and the labour are his own), enables him to get that fine tilth which is essential to him, and thereby he does not lose the moisture. Frequently with a furrow-turning plough it would happen that weeds, instead of being torn out as they would be by the digging action of the native plough, would be buried, and there are many of these in India which would speedily spring up again and form a dense matting.*

* There is surely a medium between turning up stiff subsoil and mere scratching of the surface. Ploughs which, while not turning up the subsoil, would stir it to at least six inches below the surface would surely be beneficial.—Ed. T. A.

Of the soil constituents it may be said that while phosphoric acid, potash and lime are present in greater abundance in most Indian soils than in English ones, there is a marked deficiency both of vegetable matter and of nitrogen. Black cotton-soil has been referred to as a special feature, and it is popularly supposed to be of inexhaustible fertility. Other tracts there are which every year receive a fresh renewal of silt from rivers and mountain streams, and these in the Punjab constitute the rich wheat-growing areas which need no other manuring than what the silt affords. But there are other not so desirable effects of river and flood, and often much land is cut up with ravines and rendered unculturable. Lastly there is the singular appearance of a saline efflorescence known as *reh*, a mixture of various soda-salts, principally the carbonate and sulphate. In the North-West Provinces alone, between four and five thousand square miles are thus affected and rendered unproductive. Such land is termed *usar*. The singular point is that amid these areas there are patches not only culturable, but on which some of the richest crops are grown. The problem of overcoming *usar* has long engaged the attention of the Agricultural Departments. Canals are charged with bringing it, but it is clear that it is a saline deposit existing below the surface, which, under the combined influence of water and a strong evaporating force like the sun, is first dissolved and then brought to the surface, where salt crystallise out and remain as a white incrustation.

A most interesting question, but one to which at this stage, no definite reply can be given, arises, as to whether the soil of India is, under the system of agriculture pursued, undergoing exhaustion or not. The average yield of wheat, for example, may be set at about 12 bushels per acre over the whole country, as against the 30 bushels of England. A large proportion of this goes for export, and the increasing area under wheat shown in the agricultural returns denotes that this export is one that is likely to continue. The possibility of soil exhaustion going on can only be determined by a careful study of what is removed from the land, and how far this is replaced either by the forces of nature or by the artificial replenishment of manuring. I have mentioned the deficiency of nitrogen which I observed in the case of several Indian soils, but it is worthy of note, too, how very large a proportion of the crops annually grown, also of the trees and shrubs, and even of the weeds, are leguminous in character, and may thus, if recent investigations be correct, possibly derive their nitrogen direct from the atmosphere. * * *

The next point of striking importance in the external surroundings of agriculture is the supply of wood for timber and fuel, and the provision of grazing by means of those forests which still remain to the country. There can be little doubt that India in the past has suffered great detriment both as regards its climate and its agriculture by the reckless devastation of wood and forests which has until within recent years been allowed to go on unchecked. It is, therefore, a matter of much satisfaction that now, late though it be, the charge of the forests has been put under a responsible Department, and that they are being preserved for the benefit of the State and the welfare of the people. Not that the work is complete, nor that reservation of forest land has been effected without considerable friction from an increasing population which presses its cultivation up to the limits of the forest area in the endeavour to find room for itself. But it is equally certain that the Native, if left to himself, would as speedily exterminate what remains as he has done in the past

whether by wholesale clearance for cultivation, or by excessive grazing with cattle, and, worst of all, by the destructive herds of goats. Then but only when too late, would the discovery be made how important is the relation which the forests bear to agriculture, and how essential to the latter the forests really are.

The spread of cultivation to the limits of the forests has altered in great measure the scope of the Forest Administration, which was at first non-agricultural and confined itself to the production of large timber. Now, however, the position is changed, and the Forest Department is recognising that the areas under its control must be more used in the direct interests of agriculture, and that, as far as possible, not only a timber supply for the great works of the country is needed, but also that the provision of wood for agricultural purposes and for fuel, as also of fodder and pasturage for cattle, forms part of its duties. That this is so is only fully understood when it is remembered what the *raiya*'s difficulties are in the way of providing fodder for his beasts, and when it is explained that, while the only really available source of manure is cattle-dung, this is largely burnt as fuel, and is thus lost to the land, simply because there is no a sufficiency of wood available to take its place. This agricultural loss might to a considerable extent be met by the extension of the wood-supply of the country, and steps in this direction are being taken both by the Forest Department and by the local authorities or towns. The importance of provision of pasturage and shelter for cattle in times of drought is very great, whilst etc. holding up the soil and preventing its denudation by the unbroken flow of water over its surface, the covering of the ground with trees and herbage has an indirect bearing upon the climate of the heat regions. In the course of a journey one frequently passes vast open but perfectly barren spaces over which large herds roam, these are not the *usar* plains referred to previously, but they are the "village wastes," the common property of the villagers, and melancholy examples do they afford of what the cultivators would, by excessive soaking and over grazing, do with the rest of the land now under forest, were it left to their unchecked control.

I have briefly touched on the supply of manure to the land. Of this, as stated, the only really available source is the cattle-manure produced on the holdings, and of it a great part is lost owing to its being used as fuel in the absence of wood. In Indian agriculture manure by itself is not sufficient, water is needed along with it; nor is water by itself enough, manure must go with it; the two are in fact interdependent. Could the *raiya* have both of these where there is need of them, he would be behind none in the results of his cultivating skill and diligence.—*Madras Times*.

[We cannot help feeling, with all due respect to Dr. Voelcker, that his view in regard to culture as conducted by the natives of India is too optimistic. There can be no question that deeper ploughing of grain lands and more attention to pasturage for cattle are reforms urgently needed.—Ed. T. A.]

NOTES ON POPULAR SCIENCE.

By DR. J. E. TAYLOR, F. L. S., F. O. S., & C.

EDITOR OF "SCIENCE GOSSIP."

Professor Perry, the well-known electrician, has just written a cheap and handy little book on *Spinny Tops*. It is one of the nice suggestive books I have come across for some time, intensely optimistic and almost prophetic. He holds that scientific discovery will increase during the next century in o

multiple proportion ratio. One of his concluding passages is as follows:—"Imagine the following question set in a school examination paper of 2000 A. D.—'Can you account for the crass ignorance of our forefathers in not being able to see from England what their friends were doing in Australia? Or this—'Messages are being received every minute from our friends on the planet Mars, and are now being answered. How do you account for our ancestors being utterly ignorant that these messages were occasionally sent to them?' Or this—'What metal is as strong compared with steels as steel is compared with lead? and explain why the discovery of it was not made in Sheffield.'"

This is practically an age of metallic alloys. Metallurgists are constantly experimenting upon the relative proportions of the admixture of metals. A new alloy has just been brought out whose electrical resistance diminishes with increase of temperature. It is composed of copper, manganese, and nickel. Another new alloy, brought out by the same experimenter, Mr. E. Weston, whose electrical resistance is practically independent of temperature, consists of 70 parts copper combined with 30 parts of ferro-manganese. A new luo-throwing gun has been invented, for the purpose of accurately throwing a line from the shore to ships in distress. It consists of a shoulder-gun, and the line is packed away in the stock. A rod is fastened to the line, and the gun is fired at a high elevation. But, instead of casting lines from the land to a ship, why are not ships provided with means of casting lines to the land? There would not be so many misses then.

A remarkable invention has been patented in Norway—nothing less than a new material called lactite or the "milk ivory," which is prepared from skim-milk. A factory is being built for its manufacture in Iceland. Lactite is said to bear a close resemblance to real ivory, and can be made of any colour. It is intended to adapt this new substance for such purposes as electrical fittings, buttons, door-handles, embossed panels, dials, cornices, &c.—*Australasian*.

"INGENUITY, SAGACITY, AND MORALITY OF PLANTS."

Dr. J. E. Taylor resumed his course of lectures upon the "Ingenuity, Sagacity, and Morality of Plants," at the Lecture Hall, Ipswich.

Although the immediate subject of the lecture was "Plants which catch and devour animals," Dr. Taylor commenced first by drawing attention to the constituents of plant food and the nature of that protoplasm which is the basis of all life, both animal and vegetable. He had already pointed out that the most important part of all plant food—carbon—was obtained solely from the atmosphere by the mouths of leaves. All the other kinds of food, including water, were obtained from the soil by the agency of the roots and the root hairs. During the day the leaves had attracted carbon from the carbonic acid gas in the atmosphere, and at night this was stored away in various ways, either as starch, or to build up the woody stems of trees or shrubs, or it would be carried still further to where starch was required, as in the seeds, or still underground to be stored away in the tubers of potatoes and artichokes, the bulbs of onions and liliaceous plants generally. Vegetable nature was always providing, he said, against a rainy day. Then there was a certain amount of ingenuity with which this store of food was utilised. For instance, they would observe that in herbaceous plants, or plants which had soft stems, those which lived more than one year had either underground stocks like the primrose or cowslip, or the lower part of the stem thickened into what was called a bulb, like the hyacinth, crocus, tulip, onion, etc., so that when the plants died down on the approach of winter through the frost killing the soft stems, there yet remained the vital parts hidden away underground from the keen eyes of animals that in the winter time would prowl in search of them. If they cut an onion in two

vertically they would see packed away in the centre the young plant which was to sprout in the year following. Sometimes this stowing away of vegetable starch underground would be utilized for purposes of propagation. Everybody was acquainted with the fact that the potato had so-called eyes, from every one of which potato plants would sprout, and they could cut up the vegetable with impunity as long as they did not injure this eye. This was the case also with the tubers of the artichokes. Even as regards the leaves, said the lecturer, which were to be brought forth next summer, they were already formed. If we looked upon any lilac bush, or horse-chestnut tree, or, indeed any shrub, we should find them crowded with brown buds. If these were cut in halves the leaves would be found packed away within the protective bracts, which were really modified leaves, which never became leaves, but which sacrificed themselves, for the sake of the tender little leaves which they enclosed. Even the flowers Dr. Taylor said, in some instances, that were to come next year, had been provided for last season, as in the case of the catkins of the hazel which were now shedding their pollen from the hedges by the wayside.

In all these cases the lecturer pointed out that one of the most important elements, Nitrogen, which entered into the composition of plant food, and which article we supplied to crops in nitrate of soda, was taken by the root hair of the plants from the soil. We were surrounded in the atmosphere by a huge reservoir of nitrogen, composing 79 per cent of the constituents of the atmosphere. No order of plants however except the podded plants like beans or peas, had the power of tapping this vast aerial supply. But supposing, said the Curator, that plants were so situated that these roots could not penetrate the soil to obtain any of the nitrogenous materials which the soil contained. The only means by which the soil was refreshed was by the dead bodies of animals, both great and small. Mother Earth had been for millions of years receiving back to her bosom the children to which she had given birth, microscopically small, and gigantically large. Sometimes, of course, the soil was refreshed from the atmosphere, as during thunderstorms, when the lightning flash had the power of combining in its path the nitrogen with the oxygen, and producing thereby fertilising nitrous oxide. The soil contained hosts of bacteria, which were engaged in the work of converting decomposing matter which contained nitrogen, so that it should be soluble for the root hairs of plants; nitrifying the soil, in short. Now, he said, there were groups of plants whose nature had been only studied during the last twenty years, which now went by the name of carnivorous or insectivorous. Most of them lived in marshy spots in various parts of the world. These plants, as a rule, had roots which were simply so many anchoring threads, to prevent the plant being blown away. So the duty of obtaining nitrogen was thrown upon the leaves, and these leaves, in the process of the brittle of vegetable life, and the keen strife that had been going on for ages past in the vegetable kingdom, developed special powers of capturing animals—that is to say, insects of all kinds, small fish, and even birds. The lecturer referred to, first, the sundew, of which we have three species in England. This plant was found in both North and South America, the Cape of Good Hope, and other places, but it was most prolific in Australia, where there were no less than forty kinds. All of them possess the power of capturing, strangling, and even digesting insects which visited them. By means of diagrams he pointed out the structure of these curious plants, showing how a rosette of green leaves, which were crowded with tentacles, that were really only portions of leaves extended like the fingers of a glove, secreted dew-like drops, and the greater the sunshine the greater the quantity of this glutinous material. They were exceedingly sensitive to anything touching them of a nitrogenous nature. One eighty-thousandth part of a grain of ammonia affected them. The tentacles would then flex themselves over and show that they were influenced. Microscopic examination showed the protoplasmic stream in agitation under nitro-

genous stimulant. Insects, in proportion to their size, contained more nitrogen than any other kind of creature. Along our hillsides sometimes they would see in the boggy districts a large area of the country crowded with sundews, the most remarkable plant of our British flora, and insects would be attracted by the sparkling dew to have a drink. When they alighted upon the leaf the hapless creature would be entangled among the glutinous, viscid matter, so as to be unable to get away. Then the tentacles would flex themselves over it, the edges of the leaf would curl up, the insect would be strangled and suffocated. Decomposition would set in, and the leaves actually possess the fluid pepsino like the human stomach, by which it could digest the nitrogen and assimilate it. Then the tentacles would turn to their old position, and the empty case of the insect would be blown or washed away. The Doctor then related various experiments which he had made on these carnivorous plants. Another plant growing on our hillsides was the butterwort, so called from its rosette of greasy leaves. There were certain kinds of insects called plant lice, which when they attacked the leaves of this butterwort slipped about its surface like a lanky, bad skater. These plants had also the function for digesting those insects which the leaves had captured. He next described an aquatic carnivorous plant which was to be found in the River Gipping, and they might often have seen its yellow spikes just appearing above the water level. They were regular eel traps as regarded their structure; minute water flies or the larvæ of fish could get in but they could not get out. They were strangled and digested. The Doctor then referred to the great pitcher plants of the Malay Archipelago, so huge that sometimes they held half a gallon of water, in shape they were like a hot-water jug with the cover half lifted. Small birds frequented them to drink, but having partaken, when they strive to get out they are driven back by two large pointed spikes, until at length they are drowned. In the liquid there were actually bacteria present, which helped to decompose the birds, and in this way the nepenthus plant provided itself with nitrogen. In North America there was the side-saddle plant, the sarracenia and darlingtonia, which also caught flies on their peculiar and suggestive manner, so that the interiors of their trumpet-shaped entrances were frequently crowded with flies, dead and dying. Singularly enough these plants not only had a bright attractive colour at the upper part of the trumpet-shaped tube, but they also secreted honey, and a fly lighting upon it might imagine that it was quite safe to sip. It got sweeter lower down. The interior, however, was covered with hairs, which grow downwards, and when the insect tried to come back it dropped to the bottom, to join its foolish brethren who had come the same way. They were decomposed within, and thus the side-saddle plants of America, through their modified leaves as pitchers and trumpet-like tubes, fed themselves in this remarkable manner.

THE DEFENCES OF PLANTS.

The immediate subjects of the lecture were in touch with those treated on in previous discourses, although of a distinctly individual character. Dr. Taylor brought before his hearers in the first instance the subject of the defence of plants. From what he had said concerning the usefulness of green leaves it would be seen that the loss of a single leaf was decidedly injurious to the plant. He asked them to consider the vast number of enemies which plants had to cope with, for it might be said that the whole animal kingdom depended for its existence upon the vegetable. Not only did mammalia browse upon herbaceous plants, but the larvæ of untold millions of insects did so too. In addition to these were the slugs, snails, &c., which fed entirely upon vegetable structures. Perhaps numerous spare leaves on every tree were provided for the sole purpose of meeting the demands of the animal kingdom. It is no uncommon thing during a droughty summer, to see the ground and the hedge rows stripped of their leaves entirely through the depredations of

caterpillars. What was to check the tendency of the numerous enemies of the vegetable kingdom from destroying many types of plant life. Years ago it was imagined by some people that the existence of thorns and thistles could be best accounted for by the theory of the original transgression. But botanists knew that this had practically nothing to do with the subject. Thorns and thistles were in the world long before the creation of man; and if people chose to take a too literal view of many things in the Bible, they would find themselves in error instead of in truth. The fact was that both thorns and thistles were natural defences against the enemies of many kinds of flowering plants, belonging to various orders all over the world. These defences were perhaps most strongly developed in tropical countries, where the battle of life was fought more keenly and fiercely than in temperate regions. Look, said the Doctor, upon the enormous number of substances secreted by the leaves, stems, roots, and fruits of plants. Sometimes the plant's defence would be its prickles or thorns to prevent mammalia browsing upon them, and slugs and snails from climbing up their stems—such for instance as the bramble, whose re-curved hooks also serve the purpose of grappling irons to enable the plant to climb by. Thorns were sometimes produced as stiffened hairs, as for instance in the gooseberry; others had stipules converted at the base into the same defensive material, as in the acacias. In the hawthorn the branch itself was aborted into thorns. Reference was made to the thistle, one of the finest armed plants and the most mechanically perfect in the whole world. Then, said the Doctor, the leaves of some plants were sour, like the sorrel and mountain sorrel, which contained oxalate of potash, which was really a poison, and thereby prevented slugs from eating the leaves. Sometimes the leaves were intensely acrid, like the buttercup and lords and ladies (*Arun maculatum*). The buttercup family was intensely poisonous all over the world, and he called to their mind how they would see in the dry summer time, when all the grass was close cropped, clusters of buttercups untouched by the cattle. The order of plants to which the tobacco belonged secreted poisonous materials—indeed, humorously said the lecturer, if the tobacco plant were not so it would not have been worth smoking. [Laughter.] He reminded them that this peculiar order was objectionable to most herb-feeding animals, for instance, the tomato and the berries of the bitter sweet (*Solanum dulcamara*). The poisonous character of the henbane (*Hyoscyamus*) and the belladonna, etc., The poppy secreted opium and protected itself thereby. Sparrows, he explained, would feed upon the flowers of the crocus, but they would not touch the leaves and rarely the roots. The hawthorn, the flowers of the almond tree, and the meadow sweet contained prussic acid. Many plants, especially the grasses, protected themselves by secreting a vast amount of silica in their skins. Other orders, like the crucifer, had both roots and leaves intensely pungent, as in the case of the radish, mustard and cress, etc. Some were intensely bitter, like the ferns, and these latter were seldom eaten by any animal. The tannin in the bark of trees protected them against the gnawing habits of mammalia, and the bitterness of the strychnine in our gentian family, several of which were used by medical men as tonics, was remarkable. The lecturer then went on to notice that even the perfume and odours of plants, such as the leaves of the sweet briar, mint, wild thyme, sage, &c., were more or less protective agencies not so much against animals as against the sun, for it is a fact that these perfumes kept the atmosphere cool, and they might often see sweet smelling plants flowering in the scorching sunshine, when those plants not so endowed were withered by the fervent heat. The Doctor illustrated these various phenomena by sketches upon the blackboard, as well as by coloured diagrams.

PARASITIC FLOWERING PLANTS.

Dr. Taylor passed on to another part of his subject, and an exceedingly interesting portion, namely,

that of the flowering plants, belonging to what he called highly exalted orders which got their living by preying upon, robbing, and even murdering the neighbouring plants. These remarks were illustrated by a series of mounted specimens of the broomrape, which were found in abundance on every common, and were only too well known to every farmer from their attacks upon his clover field. The collection had been made by Captain Haward, of Little Blakenham, and it showed one species of the broomrape attacking fourteen kinds of different flowering plants. Vegetable parasitism could be found in every stage. Some species only occasionally indulged in it; others, like the broomrape and dodder, could not live in any other way. The dodder belonged to the order of the convolvulus. If a seed were put in the ground, it would develop a couple of small leaves and a long, slender, sensitive stem. They might see it waving about as though it were trying to feel out for something. If it did not find anything, the plant died; if it came into contact with any succulent plant, it climbed it, and developed suckers which fed upon their host in such a manner that the substance of the latter was drawn off into its structure. When the dodder stem had once got a good hold it let go of the earth, and henceforth lived entirely upon the plant which it had embraced. The dodder killed off thousands of acres of crop plants every year. The broomrape sometimes attained a height of 18 inches; it had no roots, except one, which crept out in search of some adjacent plant until it came in contact with it when it fused itself with its victim beneath the soil. What a great vegetable bully it was, sometimes five times as large as the plant upon which it levied blackmail. The broomrape and remnants of its former leaves brown and shrivelled that were not used, so that it even did not get the carbon from the atmosphere. The mistletoe was another parasitic plant. Its home was in Australia, where the huge gum trees there sometimes contain more mistletoe foliage than their own, but the mistletoe did obtain its own carbon. Then there were other vegetable murderers, particularly in the tropics, that twisted their stems so round other trees as to strangle them. It was impossible to go into a tropical forest without being painfully impressed by the reckless selfishness and craftiness of numerous members of the vegetable kingdom. In Brazil, one of those lianas, or climbing plants, was called the murderer, because it actually spread out its stem broadly round the tree it climbed by, so as to completely encase it, and the living plant often supported within its embrace its dead and murdered victim. The ivy was also referred to. Space forbids us to enumerate other types of plants in different parts of the world which illustrated the lecturer's theory of the selfishness, craft, and seeming cruelty of those members of the vegetable world which did not get an honest living by their own roots and stems and leaves, but whose existence depended upon the ingenious, sagacious, but immoral practice of these expedients of craft.—*Ipswich paper*.

A NEW MINERAL.—Mr. H. A. Miers in the *Mineralogical Magazine*, describes a new mineral, which has been named "Sanguinite." It was observed on specimens of argentine from Chañarillo, and is probably a hexagonal sulpharsenite silver, allied to proustite. To the naked eye the mineral appeared to be göthite, but examination with the microscope revealed its different character. It has lustre, like earthy hematite; colour, bronze-red by reflected light, and blood-red by transmitted light; streak, dark, purplish brown. No quantitative examination was made, on account of the small quantity of material; a qualitative analysis, however, showed the presence of silver, arsenic, and sulphur. The physical characters as a whole prevent the mineral from being referred to proustite or xanthoconite, the mineral being nearer like the former in its physical characters. The specific gravity and hardness have not been determined.—*Public Opinion*.

NOTES ON PRODUCE AND FINANCE.

THE GROWING IMPORTANCE OF TEA.—A glance at the reports of the various tea companies issued at this season of the year, and reproduced in these columns, will convey to the reader who has no stake in tea some idea of the importance of the industry. For reasons best known to investors there is less interest taken in the City in these companies and the results of their working for the year than there should be. This is, no doubt, because there is such a limited market for the shares. When this is remedied, and transactions in tea shares are more frequent, the reports of these companies will be read with increasing general interest, and investors will be more on the alert in the matter of share quotations.

TEA AND COFFEE IN FIJI.—With reference to the paragraph in our last week's issue, in which there was some mention of an attempt to resuscitate coffee planting in Fiji, it is pointed out by a correspondent that both the coffee and tea planting experiments are failures up to the present time, owing, no doubt, to the labour difficulty; but although the difficulty should also apply to the cultivation of sugar, that industry seems to be extending rapidly, and the Colonial Sugar Company, which practically holds a monopoly of the industry of the islands, has opened out some splendid new country lately on the La Esaa River, on the large islands of Vanua Levu.

COFFEE IN MEXICO.—During the last four years, says a Mexican paper, coffee has become one of the principal products of Mexico. The new transportation facilities offered to traffic by the railways which are girding and forming a network in that flourishing republic have encouraged the coffee raisers to increase their production. In Cordoba, State of Vera Cruz, one of the principal centres of production, the cost of the cultivation of the precious grain is about 7 dols. per 100 lb. and its selling price from 22 dols. to 23 dols. and sometimes higher. This proves what has been said about the immense profits which the coffee raisers can obtain in Mexico. Next to hemp or bennequin, coffee occupies the highest place in the exportation of Mexican products. According to Mexican statistics, from 1881 to 1886 the yearly average exportation of coffee was 1,722,429 dols.; from 1886 to 1887 it ascended to 2,627,377 dols.; from 1888 to 1889 the sum was 3,866,034 dols.; and finally, from 1890 to 1891 it reached 4,841,000 dols. As can be seen, the production of coffee in Mexico has been quadrupled in the last decade.—*H. and C. Mail*, May 1st.

THE GROCER AND PACKET TEAS.—Grocers resent the action of packet tea proprietors in appointing agents outside the trade, and some of them affect a lofty tone in dealing with the question. A correspondent of the *Grocer*, writing on the subject, lays down the law thus:—"The way packers of Ceylon and other teas appoint agents seems to require an understanding amongst grocers of good standing in the retail trade. The pretended 'presenta' have done grocers much harm and deluded the public, but another serious mischief is growing. The tea firms who appoint drapers, stationers, confectioners, ironmongers, &c., as agents should be noted and avoided by grocers. Grocers' associations should occasionally have an united conference with representatives from all towns to discuss and inform all about such firms, as to who they are and the tricks and dodges played, so as to make it not worth their while to call on any respectable grocers. Today I had a traveller call to ask me to take any agency for some 'Ceylon' tea. When I reminded him that a stationer in town was agent for the firm, he replied, 'Ceylon has nothing to do with the other tea.' My remarks soon caused his exit. Another question is important: How many firms appoint sole agents and have no respect to even a written appointment, unless that written appointment is stamped! I know there are two sides to the question, but retail grocers need to discuss their own side, and large firms may be left to look after their own interests, although many firms would sell more in ten years through one good grocer

in a town than through several grocers selling a proprietary article for only a few years. Sole agents (not to monopolise) are fast becoming a necessity to enable certain packed articles to be supplied in some towns. I know a grocer who received a sole agency in writing and wisely had it stamped. After a time the firm sent a traveller to open accounts anywhere, grocers or otherwise, quite regardless of their written appointment and without notifying their agent of any dissatisfaction whatever; but the bitter was bitten, as the shrewd grocer demanded recompense for breach of contract, and obtained what he demanded, as the firm preferred pay to publicity in a court. I have no desire to interfere with legitimate trade, but high-flying professions by tea-packers and others require caution and communications between grocers. I intend stamping all future agencies I accept, as I decline being made a cat's paw to introduce to a good family trade this, that, and the other, and then, when a trade is made, let Tom, Dick, and Harry run away with the profit. Introducing goods costs time and energy, and these are not easy to obtain for money."

CHEAP TEA.—Discussing the evils of cheap tea at a public dinner, Mr. Robert Stewart, of Messrs. Semple, McLean, and Reed, tea dealers of Glasgow, said that when he entered the firm twenty-five years ago the total imports of tea from all quarters amounted to 137,000,000 lb. Last year it reached the enormous amount of 238,520,000 lb., or an increase of 91,500,000 lb. thus showing that tea, which at no remote period was considered a luxury, had become a necessary food of the people. That being so, it was much to be regretted that during the past few years there had got into the trade a number of adventurers whose only claim to public notice was their special aptitude for framing advertisements which would have brought the blush of shame to the cheek of Baron Munchausen. These advertisements the public swallowed as eagerly as they swallowed the vile concoctions which they praised. It was high time our medical authorities and the Health Committee of Glasgow Town Council should intervene, for he thought that not a small percentage of the excessive death-rate in the large centres of population could be traced to the immoderate use of low grades of an article called tea.—*Home and Colonial Mail*, May 8th.

TEA INFUSED WITH MILK.—A correspondent who, weakened by illness and unwilling as an abstainer from intoxicants to take ordinary stimulant, writes to us advocating the use of tea infused with boiling milk, instead of water. He tells us that his medical man recommended tea in this form as a most agreeable stimulant, and one which he has found very efficacious. It neutralises the tannin, and renders tea acceptable even to palates not accustomed to it, and to invalids. Certainly tea infused with milk will be found both agreeable and refreshing.—*H. and C. Mail*.

NORTH BORNEO COFFEE.—A sample of Mr. Christiano's Liberian coffee grown on the Victoria estate, Kudat, was received by Messrs. W. Jas. & H. Thompson of Mincing Lane who report upon it (on the 31st of January) as being worth 86s to 88s per cwt. A sample of Ceylon-grown Liberian coffee of somewhat inferior size, but better cured and consequently of better color, was valued at 92s. The Borneo bean has been shown to several gentlemen in the Lane who speak very favorably of its quality, and the general feeling is that African coffee is coming into favor. Messrs. Wilson Smithett & Co. state that the world's consumption of coffee is roundly estimated at 650,000 tons per annum and that supplies have steadily fallen off during the past five years. Those who are acquainted with the East are already aware of the serious deficiency in the exports from India, Ceylon, and Java, and it would appear that the present is a favourable time for planting coffee on a large scale.—*British North Borneo Herald*.

THE CEYLON TEA PLANTATIONS COMPANY.

ADDRESS OF THE CHAIRMAN, MR. D. REID,
AT THE RECENT GENERAL MEETING.

GENTLEMEN,—I am very pleased to again meet the shareholders with a satisfactory balance sheet, and to be able to assure you that, in the opinion of the Board, the position of the Company has strengthened with each successive year of its existence. Before referring to my visit to Ceylon and reviewing the Company's present position, I wish to give a few explanations of the accounts. On the debtor side of the Balance Sheet you will find that the Reserve at the end of the year stood at £3,257, while only £3,000 was carried to that fund from last year's profits; the difference—£257—is premium on new shares issued during the year. The addition proposed to be carried from the profits of 1890 to this fund will bring it up to £9,000. On the debtor side of the profit and loss account, you will find an item of £122—Furlough account. As stated in the Directors' report, £1,750 has been provided out of the working expenses of this year for this purpose, and each separate estate has been debited with the sum set apart for the Furlough of the Staff engaged on it. The £122 appearing in the profit and loss account is to provide for the Ceylon Manager's furlough. The sum of £1,750 is abnormally high, as it had to be calculated from the dates our several superintendents and assistants entered the Company's service—it is, in fact, a provision that covers not one, but four years. Now the working expenses of each year will be debited with the liability incurred during this head during that year, which will be about £600 per annum. The sum of £200 reserved for "Tobacco cultivation experiment" is an amount the Directors have set aside to cover a possible loss on an experiment they have made on a small scale in growing tobacco at Lunugala. Until the tobacco is brought to market, we cannot say whether there will be a loss or a profit. I think the accounts otherwise are plain and will be readily understood by the shareholders. Let me now refer to my visit to Ceylon. I visited, in company with Mr. Talbot, your manager in Ceylon, every estate in which the company is interested, and personally discussed with him and the various superintendents of estates the condition and prospects of the Company's property. Coming fresh from such a visit, I presume that what the shareholders will wish to know is the opinion I have formed of the value of the Company's property, the stability of its position and the character of the management. The value of our property as a profit-earning concern can be clearly seen by anyone who has read the four annual reports, which show that the position of the Company has been one of growing stability and improved prospects. I particularly directed my attention while in Ceylon to a study of the prospects of our tea continuing to give us good crops. The conditions of a good tea estate are: 1st, suitable soil and climate; 2nd, good planting with the best sort of plants; and 3rd, careful nursing while the tea is young. The actual results obtained and dividends are, I think, good evidence that the first and second conditions have been secured, and I have to state my opinion that, with very trifling exceptions, exceptions so small as not to affect appreciably the character of the whole, the Company's property fulfils the conditions I have named. Let me now say a word about the third condition, that is, careful nursing while the tea is young. If it is attempted to get large profits from tea in its early years by severe plucking, the estate may be greatly damaged and even permanently deteriorated. Amongst other things patience is required to make a good tea estate. I can assure the shareholders that our profits have not been obtained by imperilling the future. Our young tea has been treated with regard mainly to producing strong bushes that can be relied on to give large yields after arriving at maturity. In regard to the condition of the Company's property, it is in the highest state of cultivation, and has throughout a most thriving appearance. All the

factories are of the most permanent description, thoroughly well built and well-designed, and adapted for economical and efficient working. No money has been wasted in putting up fancy or show buildings, but no outlay has been grudged to give our superintendents the means of making good tea. I should like now, as has been my practice at previous annual general meetings, to take a general view of the property with which we started business this year: The cost of the properties is shown by taking the first item on the creditor side of the balance sheet, adding to it the cost of purchase of West Holyrood; Ardallie, and Rathmillockley estates, and deducting the £4,000 written off for depreciation. Taken in round figures this amounts to £223,000. Against this you have, as shown by the Directors' report, 8,307 acres of tea-planted land, and 2,831 acres of land of which a considerable portion is fit for planting with tea. Revenue has been charged with all renewals and repairs to machinery and buildings and the planting of a considerable area with timber trees. Without taking into account the Reserve fund of £9,000, and allowing £1 per acre for unplanted land, the acreage under cultivation will stand at £33 per acre as against £34 last year. This does not, however, represent all our capital assets. We have a business of manufacturing tea grown by other proprietors which last year amounted to nearly 1½ million lb., and from which a considerable profit was made. I do not, however, deem it advisable to assume our manufacturing business as representing much capital value, as our customers may at any time build themselves a factory, and so I prefer valuing your property for you solely on the basis of a price per acre for the whole business as a going concern. But, although our manufacturing business is not one we can be certain of retaining permanently, there is this to be observed—that we possess buildings and machinery sufficient to spare to deal with the crop of our own estates, not as they are now, but as they will be when every acre shall be in full bearing. I can best give an idea of the extent and completeness of the Company's equipment, when I tell you that in January, February and March of this year we made at our own factories over one million lb. of tea and three large factories, viz: Mandama, Rosita and Taagakelly, were not completed, but all three will be at work on or before June 1st of this year. After these factories are finished, we shall be in a position to deal with considerably over four million lb. of tea per annum. Taking these facts in conjunction with the Directors' report which shows that during 1890 a profit of over £31,000 was made from a plucking area of less than 4,000 acres, I think I am justified in describing the Company's position as one of growing prosperity and stability. I should like now to say a word about the expansion of the Company by new purchases, and I have to inform you that since issuing our report the Directors have concluded negotiations for the purchase of the Yoxford estate from Messrs. Baring Bros. for £18,000. I am, after careful inspection and consideration, well satisfied with all the Company's new properties, and I am no less pleased to be able to assure the shareholders that I see no signs of deterioration in our oldest estates. The Company's estates in the Kelani Valley are looking healthy and vigorous and have given very heavy crops during the present year. The situation of the Company's factories is generally most favourable for siding one another in times of pressure or break down, several of our large factories being at railway stations, and all very accessible by road. Let me now say a word about the management in Ceylon. Any property, however fine, may easily be ruined by mis-management, and I have given anxious attention to the consideration of the efficiency of our staff. I have the fullest confidence in assuring the shareholders that no property in Ceylon is more carefully or skillfully managed than is their property by Mr. Talbot and the able superintendents and assistants who form the Company's staff, and I have to express my great satisfaction with the excellent feeling of mutual respect and trust which I know exists between the Board of

Director and our Ceylon staff, and which I believe lies at the root of the successful working of any business concern directed by a London Board carrying on an enterprise in a country 5,000 miles distant, I desire also to record the thanks of the Board to our Secretary for the admirable manner in which the duties of his office, embracing, as they do a great deal of laborious work, have been performed. I have now much pleasure in moving the adoption of the report and balance sheet, and that a final dividend of 8 per cent. be declared payable forthwith.

This *Home & Colonial Mail* in a very brief summary of the meeting says:—

In reply to questions by shareholders as to gross figures resulting in the substantial net profit of £30,000 shown at the credit of revenue account, the Chairman stated that the profit on the tea produced on their own estates amounted to, roughly, 4d a lb and the profit (or commission) on the crops purchased to about 1d a lb out of the 11d gross product. One shareholder expressed a desire that a little more broad details might be introduced in future into the accounts, the same as used to be given in previous years; while another gentleman present suggested that the system followed by the Indian Tea Companies of giving total Ceylon expenditure and total produce realisations, or a fully detailed tabular statement such as is presented by the Land Mortgage Bank of India (the largest Indian tea Company) would be an advantage. The Chairman, however, indicated that the feeling of the board was in favor of keeping such information private, but that individual shareholders could, if they desired it, be furnished with information, and that at the meetings the chairman would also be ready to give all reasonable information. The meeting was then made special, and resolutions were passed authorizing the board to acquire, at a cost of £27,000, properties with an aggregate area of about 1,000 acres, about half of which was under tea and coffee cultivation. A cordial vote of thanks to the board and staff for their efforts to bring the Company to its present state of success terminated the proceedings.—Local "Times."

CINCHONA IN JAVA.

From Mr. van Romunde's report on the Government cinchona enterprise in Java for the first quarter of 1891 we learn that the weather was somewhat abnormal, heavy rains alternating with drought. This was unfavorable for the young plants, and the Ledgeriana seedlings suffered in consequence. By the end of the quarter the planting up of new grounds intended to round off the plantations on the Malabar hills was as good as finished so far as those intended for ledgerianas were concerned; whilst the succirubra plantations uprooted in 1890 and during the last few months were replanted with ledgeriana. The restoration of the older ledgeriana plantations by close interplanting was vigorously carried on. In order to diminish the cost of upkeep of plantations, the distance between ledgeriana seedlings was diminished. Especially in second planting the distance was reduced to a minimum, after it had been ascertained that on land planted for the second time with cinchona, a vigorous growth commences only when the soil is shaded from the effect of the sun's rays. The crop of 1890 comprised 534,562 half-kilograms bark, of which 142,396 $\frac{1}{2}$ -kilos *C. succirubra*, 6,447 $\frac{1}{2}$ -kilos *C. Josephiana* (*C. calisaya schuhkrafi*), 312,271 $\frac{1}{2}$ -kilos *C. ledgeriana*, and 43,448 $\frac{1}{2}$ -kilos *C. officinalis*. During the quarter about 100,000 pounds of bark were gathered. At the end of March a commencement had been made with despatch of the bark. On 22nd Jan. and 26th Feb. sales of bark of the crop of 1890 were held in Amsterdam. The unit for manufacturer's bark at these sales averaged 7 $\frac{1}{2}$ and 7 cents. Good prices were paid for ledgeriana barks, whilst for succirubra bark one meter in length up

to f1.32 and f1.40 per $\frac{1}{2}$ kilo was paid. In January and February sales of cinchona seed were held, the amount realized being f397. The lots offered consisted almost entirely of succirubra seed. Through the carelessness of a fixed labourer a fire took place in one of the houses at Lembang, whereby the kampong attached to that establishment was reduced to ashes.

THE DUTCH MARKET.

AMSTERDAM, April 29th.

CINCHONA.—The bark sales which will take place here on May 14th 1891, will consist of 3,313 bales 75 cases—total about 289 tons—divided as follows:—*Java bark*: From Government plantations 330 bales, 22 cases, about 29 tons; from private plantations 2,983 bales 53 cases, about 260 tons. *Druggists' bark*: Succirubra quills, 54 cases; broken quills and chips 170 bales; root, 14 bales; C. Anglica quills, 11 cases. *Manufacturing bark*: Ledgeriana broken quill and chips 2,167 bales; root 700 bales; byrides quills, 10 cases; broken quills and chips, 96 bales; root, 120 bales; officinalis broken quills and chips, 28 bales; root, 18 bales. Total, 3,313 bales 75 cases. The analyses are not yet completed.—*Chemist and Druggist*.

SMALL CULTURE UNDER GLASS:

(Commercially Considered.)

BY ARTHUR SINCLAIR.

These serve for useful ends, when frosts by night, Or cold, raw winds the tender blossoms bite.

—Lawrence.

Aberdeenshire farmers are generally recognised as being, to say the least, quite abreast of their brethren in the most advanced and best cultivated portions of the world. The same, however, cannot be said of our gardeners and small outcultivists. Our farmers, considering the brief summers in our northern latitude and far from rich soil, contrive to raise crops and cattle which might well, and does, excite the envy of agriculturists in more favoured climes. Indeed, I doubt if any of our numerous colonies, producing only one crop a year, yields a greater quantity of food per acre than "poor bleak Aberdeenshire." But, while farming has made wonderful progress during the present century, gardening has progressed backwards, the lack of encouragement from the degenerate successors of former patrons and the difficulties to contend with in the shape of an uncertain climate being deemed sufficient to account for this. The time was when the M'Intosh of the north was encouraged to vie with the Paxton of the south; but nowadays, the tastes of my lord and lady find a more congenial if less reputable field in other directions.

But a new patron has arisen for the encouragement of the horticulturist, even the great public itself, with a newly acquired taste for fresh vegetables, native, sub-tropical, and other tender greenery in and—especially—out of season. This ought to be encouraged, and, indeed, being fostered by many shrewd cultivators in Kent, Guernsey, and elsewhere, who have already acquired fortunes by the supply of those delicacies; and it is a desire to see Aberdeen sharing in this good fortune that prompts me to write this paper.

The demand at present seems practically unlimited, and I hope to be able to show that the possibilities of supply from Aberdeenshire are as great as from any country in Great Britain.

The culture of fruit and vegetables under glass has hitherto been looked upon as one of the luxuries of the very rich, and until recently the cost of glass practically prohibited its use on a large scale. It was thought also that our northern winters were too severe, and, moreover, there was no market till the taste

was cultivated. This latter difficulty having been got over, all the others must follow. *Forcing* is not absolutely necessary, assisting nature and watchfulness being all that is necessary; and if this is judiciously attended to, two or even three crops a year may be successfully taken from our soil, and fresh supplies sent to the city markets all the year round.

It has been sufficiently demonstrated that Aberdeenshire, particularly Deeside, is quite as much favoured in the matter of light and sunshine as Kent—the garden of England. It is true our springs are later, our summers shorter and more uncertain, but the almost invariably genial autumn and as a rule milder winter more than make up for this, while the very nature of our undulating land gives us a great advantage over the flat, misty lowlands.

Yet such is the fact that, while hundreds of acres have been covered with grass and little fortunes made by growing early potatoes and tomatoes in the foggy fens of the south, the enterpriser can scarcely be said to have been initiated in Scotland. This is far from creditable to Aberdeenshire.

At the present moment, potatoes from the south may be seen selling in Union Street shops at 6d per lb. Is there any earthly reason why these should not be produced locally? or, indeed, looking at the average winter temperature of the respective localities, why a daily supply should not have been sent from here to the south of England during the past two years?

The cost of the necessary glass structures need not be prohibitive, nor the cultivation beyond the capacity of any labourer of ordinary intelligence. The chief source of anxiety, viz., how to protect the crops from sudden frost or blasts of cold east wind, is more easily provided against than generally supposed. A covering of coarse canvas, and when necessary—which is very seldom—a simple heating arrangement. As a rule, there is far too much heat and coddling in our glass houses. A much greater enemy than cold is the indiscriminating use of the watering pan during winter.

The situation is important—a rather more than gently sloping brae side, facing the southeast, on such a declivity as radiation will go rapidly onward, and the cold condensing mists roll down to the bottom of the valleys, chilling with frost what many are apt to call “the warm sheltered spots,” while the hill above is left quite unscathed.

The sub-soil is the next consideration, and this must be open, free, inclined to gravel, the surface soil being made to suit the several crops. The necessary water will suggest itself; so will also proximity to the city or railway station.

The buildings may be erected according to taste and means, but the lower or nearer the glass is to the surface of the ground so much the better. The cost—according to figures obligingly supplied by friends in the south of England—averages from 9d to 10d per superficial foot—say £1,633 per acre—a formidable sum certainly; but let us look at the average returns:—

The local demand, or Covent Garden Market, must dictate the nature of the crops. At present I shall only instance potatoes, tomatoes, and kidney beans, of which I have before me reliable returns, the wholesale prices received in London being as follows:—

Potatoes	4d to 1s 0d	per lb.
Tomatoes	3d to 1s 3d	..
Beans	4d to 2s 6d	..

Now a very moderate estimate would give 5 tons potatoes to the acre—

Say 11,200 lbs. at 6d	£280
Tomatoes, say 10,000 lbs. at 6d	250
	530

Interest on capital, taxes, rent and labour, say	230
--	-----

Leaving a profit of £300

I have thus shown what might be done by growing two crops a year, but of course rotation of crops will have to be studied. All kinds of salad abund-

antly supplied, the strawberry will suggest itself, and grapes may be grown without interfering with the winter crops of vegetables.

The best potato for the purpose is the good old Ash-leaf variety, though some of the round are more prolific. Yet, as a rule, it is a profitless chase running after new varieties. There is quackery in other things than drugs.

The main planting ought to be done early in October, so as to be ready for the market by the 1st February. These being cleared out by 1st March, the ground is forthwith filled with nice, sturdy tomato plants, which will have to be in readiness for planting. These will give an abundant supply from June to September.

“But the ground requires rest and wintering,” say some—a very convenient theory, no doubt; but, nevertheless, an utter fallacy, the lazy fallow system having been long ago exploded by the practical husbandmen in the East.

We are, after all, but comparative novices in the art; 150 years ago our great-grand-fathers knew about as much of agriculture as the Esquimaux, and, marvellous as the progress has since been, we ought not as yet to be above learning of nations who have practised the art for thousands of years. In India may be seen fields which from time immemorial have been growing two or three crops a year. In China, I believe, the same. Born and bred to the business for ages, the Chinaman is, without any exception, the best gardener in the world; he may not know all the mysterious mintage and ponderous names with which my lord's great gardener delights to mystify the budding amateur, but—

He knows to give each plant the soil it needs,

To drill the ground and cover close the seeds;

And could with ease compel the wanton rill

To turn and wind obedient to his will.

Depend upon it, the day must come when a very great deal more will be taken out of the soil here than ever yet has been, and those who most directly contribute to this end will be deemed the best of benefactors.—*Aberdeen Free Press*

TEA AT HIGH ELEVATION.—The P. & O. mail steamer on Thursday (May 28th) takes away, among others, Mr. Chas. E. Strachan, after one of his periodical visits to the Colony. He is highly pleased with the growth of tea, especially in the higher districts, in the Agras and Bogawantalawa, and thinks even in production they will beat the lowcountry. One place belonging to Mr. Strachan estimated on the planting to give 300 lb. an acre of tea, is giving 500 lb. and may go on to 600 lb. and more, and of fine tea too. We mentioned on Saturday that Gallaha Factory belonging to Mr. Strachan's firm was likely to put through 500,000 lb. this year; a figure fifty per cent higher would be nearer the mark. We learn from upcountry that nearly 100,000 lb. was put through in April alone. Tea leaf is carted 8 miles to this factory without any harm being sustained.

MILDEW.—A circular has been prepared by Professor B. T. Galloway, and issued by the Department of Agriculture, on the treatment of nursery stock for leaf-blight and powdery mildew. The Bordeaux mixture and the ammoniacal solution, both of which preparations have been often described in this paper are alone commended for use. The circular gives directions for applying these remedies to the various kinds of trees for the different diseases and gives illustrations of the most effective pumps and nozzles which have been devised for spraying. Apple-seedlings, it is stated, can be treated with the ammoniacal solution five times at a cost of eight cents a thousand, while the Plum, Pear, Cherry and Quince can be treated six times the first season with the Bordeaux mixture for fifty-five cents a thousand. These are certainly inexpensive remedies, and they are reported to be very effective. This little circular of eight pages will be forwarded by the Department to any nurseryman or fruit-grower on application.—*Garden and Forest.*

"COFFEE" AND THE DECREASE OF POPULATION IN THE CENTRAL AND UVA PROVINCES.

THE HOST OF LOWCOUNTRY DEPENDENTS ON "COFFEE"
WHO MUST HAVE DISAPPEARED WHEN COFFEE WENT.

A well-informed correspondent thus indicates how native population in the coffee districts of the hillcountry must have melted away with the disappearance of their means of subsistence, direct or indirect, in coffee. Not simply did the Kandyan villagers suffer, and to some extent, being sold out, migrate; but a much larger host of lowcountry boutiquekeepers, artificers, servants, carriers, *et hoc genus omne* had to move and return to the maritime districts. We quote as follows:—

"It is clear that the damage suffered by the loss of coffee, *i. e.* the actual loss of income to villagers, was far larger than the Government has ever fully realized. This bears very strongly on the latest folly of 'the philanthropist,' that the reduction in numbers in the Central Province shown by the past census is due to sales for grain tax. It is of course due to the loss of coffee which has produced the removal from the Central Province and above all from the lines of the great highways, to other parts all that large alien population which lived by coffee, either by its growth or by its transport.

"And one proof is this. In Kandy District proper there are three Ratamahatmayas' divisions, the collection of the tax in which has been always made without restraint; in fact where the tax is borne with ease,—Harispattin, Pata Dumbara, and Pata Hewaheta. There are three where there has always been difficulty and some, but, except in the second, not many, sales,—Tumpana, Uda Dumbara, and Uda Palata. It should follow, if the philanthropist is correct, that the population of the first three should have increased or at the worst remained stationary—and that the population of the last three should have diminished. As a fact they have all (except I think Tumpana which has increased) diminished in much the same proportion.

"You have yourself hit the blot in pointing at Matale District, where the tax has always been collected without difficulty, but which has lost 13 per cent. Matale has lost more than Walapana!"

Yes, Matale lost the lowcountry boutiquekeepers, servants, artificers, &c., &c., who were supported by the coffee enterprise. But of course, the diminished population will continue to be traced in certain quarters to the "oppressive" rent of rice lands.

RAINFALL AT LABUGAMA.

For five years on Labugama estate:—

	Rainfall
From 1st January to 31st December 1886	148.57.
The highest fall during this year was on	
May 13th	5.53
From 1st January to 31st December 1887	161.22
The highest fall during this year was on	
April 27th	6.40
From 1st January to 31st December 1888	144.82
The highest fall during this year was on	
May 26th	6.04
From 1st January to 31st December 1889	171.30
The highest fall during this year was on	
April 29th	6.12
From 1st January to 31st December 1890	143.09
The highest fall during this year was on	
May 28th	6.00
From 1st January to 22nd May 1891	62.84
The highest fall during this period was on	
April 7th	7.30

[So that the highest daily fall is credited to 1891.—Ed. T. A.]

BARK AND DRUG REPORT.

(From the *Chemist and Druggist*.)

London, April 30th.

ANNATTO.—A parcel of 12 packages bright Ceylon seed is held for 2½d per lb., an offer at 2½d being declined; another lot of damp seed sold at 1½d per lb.

CINCHONA.—The large supply of 233 bales Goayaquil bark was nearly all disposed of with fair competition, 209 bales selling at somewhat irregular, but on the whole steady, prices: good silvery and mossy quill 8½d to 9½d; medium to bold brown ditto 8d to 7d; mossy chips 5d to 6½d; brown ditto 8d to 4½d; split in thin chips 3d down to 1d per lb. Of flat Cinchona 5 serona damaged sold at 9s to 1s 2d; 74 packages flat damaged Carthagena bought in at 8d per lb., only one lot, very badly damaged, selling at 4d to 5d per lb. The following figures refer to the exports of cinchona bark from Java during the eight months between July 1st and February 28th:—

	1890-91	1889-90	1888-89	1887-88	1886-87
	lb.	lb.	lb.	lb.	lb.
Private plantations	4,838,065	8,012,630	2,244,870	2,001,171	1,125,310
Govt. plantations, Amst.	404,645	804,780	529,110	490,653	480,777
Total	5,242,710	3,407,410	2,773,980	2,491,824	1,606,087

THE SALE OF FINE TEA.

We are pleased to find that our recent articles on this subject have been largely reproduced by the grocery press in America, and have elicited general expressions of approval. The same advice that we have given to English grocers—*v. z.* to sell as fine a quality of goods all round as they possibly can—is also given by our contemporaries to the grocers of America, and almost exactly the same line of argument is used. Thus the *Canadian Grocer*, after republishing an article from this journal, wherein our readers are advised to avoid low-priced rubbish and push higher class teas, says:—

The above will answer quite as well for American grocers. Last year the imports of tea were large, but the declared value of the 89,249,443 lb. imported was little over 15 cents per pound! This does not indicate a very high grade of tea, and reveals one reason why our people prefer coffee or beer, for the two latter have become national beverages, we using about sixteen gallons per capita of coffee, and twelve gallons per capita of beer per annum, to about six gallons of tea. There are both profit and satisfaction in handling fine tea. It makes trade. Customers as soon as their attention is directed to the matter, will discover that there are pronounced differences in flavor and come to appreciate the delicate fragrance of a fine leaf instead of as now, being satisfied with any sort of an infusion so long as it is warm. People will soon learn that a high-priced tea is very little more expensive than a cheap tea. The Ceylon factors impress upon their customers that their "money can go as far in \$ 1.25 tea as in a 50-cent tea, that is, good tea can be cheap." . . . This country should use 240,000,000 lb. annually instead of 80,000,000 lb. but that day will not come until the average value per pound of the imports of tea is raised from 15 to 30 to 40 cents per pound. Fine tea becomes a subject of tea-table gossip, and sets tongues wagging the same today as in Ben Jonson's time. Hence to build up a paying tea trade the dealer should abandon the sale of poor, inferior, or low-grade tea.

This is sound common-sense, and may be studied with advantage not only by the grocers of America but also by those in this country. The public, after all, do not like low-priced, inferior goods, and are generally induced to purchase them only by the absence of anything better. If they are offered the chance of buying really fine tea and other goods of a similar character, they do not, as a rule, stand out for the sake of a few pence per pound, but prefer the superior commodity. Grocers should most carefully study their taste in this respect, and strive to supply only one class of goods, *viz.* the best.—*Grocer.*

MICROPHONES.

EVERY ONE HIS OWN MICROPHONE MAKER.

Mr. J. J. Smith, discoursing to the members of the Chemists' Assistants' Association, pointed out that it is easy for those who are disposed to amuse themselves in this way to make an instrument which would render audible the footsteps of a fly. The little apparatus consists of a box with a sheet of straw paper stretched on its upper part. Two carbons, separated by a morsel of wood, and connected with the two circuit wires, are fastened to it, and a carbon pencil, placed crosswise between the two, is kept in this position by a groove made in the latter. A very weak battery is then, we are assured, sufficient to set the instrument at work, and when the fly walks over the sheet of paper it produces vibrations strong enough to react energetically on an ordinary telephone. No doubt the young generation will be disposed to try its hand.—*London Daily News*, April 24th. [There is nothing to hinder those who have electric lights, telephones, &c., to make one of these small microphones and turn them to practical account.—*Cor.*]

CEYLON, INDIA AND CHINA TEA.

(From the *Financial Times*.)

There is now so small a quantity of China tea left for displacement that a still larger home consumption of dry tea in the future is regarded as inevitable. At the same time, the rate of exchange tends to check supplies from China, as we have previously explained, and the Indian crop is about ten millions of pounds below the original estimate. These causes, combined, have produced the higher prices recently recorded. Other diagrams in Messrs. Gow, Wilson and Stanton's circular show the consumption of tea in various lands in the periods 1880-4 and 1885-9. From these it is seen that Great Britain is far ahead of all other countries as a tea drinker, the United States coming next, then Russia, then the Australasian Colonies, and then Canada. Of the countries of the European Continent, Holland is the largest tea consumer, the quantity it disposed of being about three hundred thousand more pounds in the latter five years than in the five preceding. In the other Continental countries the taste for this beverage makes little headway: The enterprising brokers, from whose circulars this information is derived, seem to glow with a patriotic zeal for the popularity of the India and Ceylon teas as British products, and what they show as to the superiority of the article, both in strength and in quantity of supply, would almost suggest "Briannia rules the tea market" as a future national anthem.

The circulars with coloured diagrams which Messrs. Gow, Wilson and Stanton issue every now and then may be said to form the pictorial literature of the tea-trade. The charts are ingeniously contrived, and show at a glance the nature of all important movements. In one just issued we are able to see, from the arrangement of blocks of varied hues, how the quantities of India, Ceylon, and China tea consumed respectively in Great Britain have varied, not only as regards the weight of dry tea from those countries, but also, roughly speaking, as to the numbers of gallons of liquid tea drunk. A report of the Board of Customs has shown that Indian tea goes half as far again as Chinese tea, so far as depth of colour and fulness (not delicacy) of flavour are concerned. Thus, while one pound of Chinese produces five gallons of tea, a pound of Indian will produce seven and a-half gallons. Basing their calculations on this estimate, Messrs. Gow, Wilson and Stanton show that in proportion as India has supplanted

Ceylon tea in the market the consumption of the beverage has increased, and the extent to which it is demonstrated to have done so is necessarily enormous, on the principle of reasoning adopted. While in 1890 we got less tea from China, and more from India than in 1889, the displacement was not nearly so great as in the preceding years. Thus the increasing demand of the population for the "cup that cheers without insinuating" could not be met, as it had been, by mere substitution of a strong tea for a weaker one, and the result was a larger aggregate use of the dry leaf.

INDIA AND CHINA TEA.

To the Editor of the *Financial Times*.

SIR,—In your interesting article which appeared today upon the growth of the trade in Indian and Ceylon teas a printer's error has crept in which might cause injury to one of those industries.

Our report from which your quote is said to show that "in proportion as India has supplanted Ceylon tea in the market the consumption of the beverage has increased," etc., the word Ceylon being inadvertently used instead of China. China tea has during many years past been largely displaced by the stronger teas from India and Ceylon.

We feel sure that, in justice to the Ceylon tea industry, you will kindly insert this letter in your valuable journal.—We are, &c.,

Gow, WILSON AND STANTON.

13, Rood-lane, London, E.C.,
10th April 1891.

CEYLON TEA IN AMERICA: MR. ELWOOD MAY AND THE LONDON CEYLON ASSOCIATION: FAVOURABLE RECEPTION—MR. RUTHERFORD'S SCHEME—CEYLON AND INDIAN TEA COMPANIES.

LONDON, May 8th.

Mr. Elwood May has had the opportunity during the present week of conferring with many members of the Ceylon Association in London on the subject of those proposals of his which have been so widely debated and so strongly criticized. On Monday last Mr. May met at the Association rooms the following gentlemen, and it is a matter of much regret to me that it is impossible for me to include my own name in the list. There were present on the occasion mentioned:—Messrs. J. Hamilton, W. J. Thompson junior, T. Stretch, J. L. Shand, W. Haslam, W. Bentham, W. W. Mitchell, A. G. Stanton, A. L. Hutcheson, T. Gray, W. C. Rodhe, H. K. Rutherford, J. F. Churchill, J. Capper, C. J. Scott, J. Anderson, S. J. Wilson (of Messrs. Wilson, Smith & Co.), and R. A. Cameron. It is not in my power to give you a detail of all that was said at the interview had by Mr. May with these gentlemen, whom you will acknowledge to have constituted a very efficient representative of the tea industry of Ceylon. The net result, however, of the discussions which took place I am fully competent to afford you knowledge of.

It may at the outset be stated that Mr. May came to this meeting with views very materially modified as compared with those he submitted in his letter to the Ceylon Association to which a previous letter of mine made reference. He acknowledged to the meeting that his experience gained since his arrival in London had made him recognise the fact that it must prove futile to endeavour to carry out that section of his propositions to which in my previous notices of this subject the term "cornering" has been applied. This had been foreseen by all of us as what must be the conviction to be ultimately forced upon Mr. May; though at the time of my last writing he

had refused to recognise the fact. But he seems to have made out a very good case for several of the other proposals which were embodied in his letter above referred to, and his request that he should be given by the London Association a sort of official *locus standi* appears to have met with considerable approval.

Mr. May urged that were that standing secured to him—in some way or other, were the company he represents in America able to point to recognition by your representative bodies in London and Ceylon, his hands would be very greatly strengthened. He did not ask for monetary support, only the adoption of such resolutions by the Association as by their quotation would induce reliance by the American public upon the good faith of his protestation that his Company would sell none but pure Ceylon tea, and that it was in a full position to obtain it. The general sense of the meeting was that this demand might justifiably be met, and that resolutions which should assure to Mr. May the recognition he asks for might well be passed. Several such resolutions drafted by Mr. May were submitted by him, but the time at the disposal of the meeting did not admit of these being fully discussed, and a second meeting is to be called in order that they may have due consideration. As regards the *principle* of affording the amount of support asked for there does not seem to have been any dissentience, it being the generally adopted opinion that something should be done to back up the enterprise in America, and that the adoption of Mr. May's present proposals, involving, as they do, no expenditure, might well be that something.

Mr. Rutherford has suggested a more extended support being given to Mr. May. He proposes that the Company of which that gentleman is the President should be constituted the recognised agency for the due representation of Ceylon tea at the forthcoming World's Fair at Chicago. With this interest Mr. Rutherford has suggested that the Ceylon Tea Fund should devote the whole of one year's income—estimated, we hear, at somewhere about 50,000 rupees—to the support of such representation, on the condition that each subscriber to the Fund of 50 rupees should become entitled to a fully paid up 2 dollar share in the American Tea Company now established. Mr. May, we understand, would have no objection to subscribe to such a condition, which would, however, necessarily have to be ratified by those associated with him in the Company. This suggestion by Mr. Rutherford will receive consideration when the Committee meets to deal with the resolutions proposed by Mr. May for adoption, and it will then have to be decided whether the Association shall recommend the management of your Tea Fund to agree to the arrangement suggested.

The two announcements given below appeared in the *Times* of Tuesday last. I have given them to you as they were printed in that paper, because it struck me that their following the one upon the other, must certainly direct public attention to the great contrast between the results achieved by Tea Companies working in Ceylon and that which has its enterprise in India. You recently wrote as to the relative dividends declared by the Indian tea companies and those of Ceylon, and we think you will acknowledge that few stronger cases of contrast could be adduced than these two announcements afford. You will receive a copy of the report of the Scottish Ceylon Tea Company of which the following is a brief abstract, and will be ready, we know, to congratulate the directors and shareholders upon the highly satisfactory results to the year's working that it discloses,

The report of the directors of the Scottish Ceylon Tea Company (Limited) for year ending December 31st 1890, shows a profit of £7,868, making, with the balance of £169 from 1889, a total of £7,537 available for distribution. Out of this sum a dividend at the rate of 4 per cent. (free of income-tax) has already been paid and the directors now propose a further dividend of 11 per cent. (free of income-tax), making 15 per cent in all for the year. Of the balance it is proposed to place £1,000 to a reserve fund, carrying forward £287 to next account.

The report of the directors of the Darjeeling Company (Limited) made up to December 31st, 1880, shows that the quantity of tea manufactured in the season of 1890 amounted to 606,950 lb., being a considerable increase of 57,172 lb. over the crop of 1889, but the tea brokers have informed the directors that the usual high standard of quality was not maintained, and, consequently, the average price realized for the crop is only 1s 0.66d per lb., against 1s 2.10d per lb. for the crop of 1889, showing a decrease of 1.44d per lb., which, on the whole quantity disposed of, represents a deficiency of £3,573. The proportion of teas of this quality was unusually small during the past season, and high prices were realized for them. Out of the profit on the season's operations the following claims have to be provided for:—To commissions to staff, £843; to income-tax, £222; leaving a net profit of £6,266, which is equivalent to £4 12s 6d per cent on the paid-up capital of the company; and it is therefore proposed to transfer from the undivided profits the sum of £1,859 in order to provide a sufficient amount to enable the members to declare a dividend at the rate of 6 per cent for the past year. So far the prospects for the season 1891 show an improvement over last up to the middle of April, but the quantity of tea manufactured up to that early period of the season has always fluctuated considerably.

We suppose the telegraph will have informed you of the fact that the record has again been beaten, and in a most crushing degree, as regards the sale of the Ceylon gold tip teas. When Gartmore astonished the world there were few who thought the price its production obtained could be beaten, but when writing you relative to that sale my opinion was expressed that as the higher the price paid the greater the advertisement, there would probably be a great increase in the amounts obtained for these artificial teas until some ridiculously high limit was attained. Therefore it is that although a parcel of Ceylon tea from the Oriental Bank Estates Company's Haywards Estate sold on Tuesday last at the auction in Mining Lane for £17 per lb or over one guinea an ounce, I feel no surprise, and shall go on quietly awaiting the time where some other and less costly form of advertising occupies the minds of speculative traders in the tea business. *The Globe* thinks that the tea men must have *delirium teanens*!

Sir Walter Selland took a prominent part in the discussion upon Mr. Morris's paper on the subject of the Leeward Islands at the Colonial Institute the other night. He declared that Mr. Morris's recommendations while in those islands as to the utilization of fibre plants had an immediate effect, and caused orders for machinery to be at once sent home. This may have been so; but it is within my own knowledge that some time prior to Mr. Morris's visiting the Leeward Islands, an article in the *Engineer* on the subject produced immediate inquiries by the authorities of one of the islands included in that group. Capital is what is wanted to stimulate these new enterprises, and it is certain a great number of suggestions which promise fairly fall through for want of such support.

Some remarks have been made above with reference to Ceylon tea having been sold during the present week at £17 the pound, and they included a conjecture that we had not even as yet

seen the limit at which advertisement of that kind may be profitably made. Having thus far written my letter, my eye caught a paragraph in the *Times* of this morning which informs us that at the sale room yesterday Messrs. Gow, Wilson & Stanton sold a small lot of golden tip Ceylon tea from the Gartmore estate to the Mazawattee Ceylon Tea Company at £25 10s the pound! Well may the *Times* remark as to this that it is "a price which has never yet been approached." It will be unsafe to hazard even a conjecture if at this rate we have reached the economic limit and whether the advertisement market will prove now to be glutted with these abnormal preparations of tea. It is certainly singular that no tea of this kind has been sent from India, Ceylon as yet stands alone in the supply of it, and the fact of course gives exceptional prominence to your produce in all conversations arising out of these extraordinary sales.—London Cor.

TEA AT £17 AND £25 10s. PER POUND.

The recent sales of Ceylon tea at £17 and £25 10s. per pound have attracted a good deal of attention from the English newspapers. The *London and China Express* says that there appears to be "no limit to the price which tea dealers are willing to pay for the fancy parcels of Ceylon tea which have of late been put upon the market. It will soon be equal in value gold dust itself." A description is given of the sale of the Haviland parcel on the 5th inst. at £17 per lb., the bidding beginning at ten guineas and rising by half crowns and crowns to the sum for which it was ultimately knocked down and which is equal to a guinea an ounce; and with regard to the sale two days later when £25 10s. per lb. was paid by the Mazawattee Ceylon Tea Company for "golden tips" from Gartmore it is stated that the price beginning at 10 guineas was run up within a minute to £20 when it proceeded by crowns and half sovereigns till the £25 10s. was reached. During the sale the room was packed to suffocation. The *Financial Times* has a prominent article on the sale headed "Worth Nearly Half of its Weight in Gold," and the *Daily News* and *Daily Chronicle* have also sketches of the exciting scene in the auction room. Announcements regarding the purchase by the Mazawattee Co. also appear in the advertisement columns, and altogether there is perhaps at the present moment no article of commerce which is kept more prominently before the mind of the British public, than Ceylon tea. From the *Globe* of May 8th we quote the following paragraph—"Apropos of the high price paid for tea yesterday—the record at present stands at £25 10s. a pound—a correspondent writes to suggest that Mr. Goschen should consider the advisability of employing tea leaves as one pound notes. We offer this Golden Tip to the Chancellor of the Exchequer for what it is worth."

WYNAAD PLANTING NOTES.

COFFEE CROP PROSPECTS—LIBERIAN COFFEE.

As the subject which is most prominently forcing itself upon our notice, I must commence this letter with the weather. This has been most unusual, and in some respects satisfactory, as our very early showers fell just sufficiently, and then had the grace to hold off long enough to allow the blossom to set. This arrangement occurred on four distinct occasions, so that most of us have had four separate blossoms on our trees. All last month thunderstorms and rain

were so continuous that the climate has become more like that of the mousson, than what we might expect in an ordinary "hot weather" season. The nights, early mornings and evenings are pleasantly cool, but there is a steamy heat in the middle of the day which brings our men folk in from the field panting for any sort of cooling beverage. The country is as green and lush in growth, as if it were September instead of May. The coffee looks splendid. I have never seen the berries such a size, so early in the season, but we are rather quaking at the thought that all this extra moisture is not unlikely to bring on again our dreaded foe, leaf disease. At present, it is simply marvellous how the estates have recovered themselves, which some months ago seemed almost positively doomed.

Crop prospects, therefore, may be generally regarded as very fairly favourable; and a corresponding cheerfulness would reign amongst us could we all feel that our future was as secure as our next crop. But there is no use in attempting concealment in a matter which is every day becoming more patent to the experienced coffee-planter. The death warrant of Arabica has gone forth, and it must be only a matter of a few years, when its place amongst us will know it no more. The old fields hold on where the borer does not finish them, but the present heavy crop will probably shake many of them beyond recovery. The disheartening fact is that it is the young plantings on which we should naturally rest our hopes, and these are proving a constitution so undermined by leaf disease that it is not probable that even the most promising of them can be lasting. I do not think from what I can gather that the idea of grafting coffee is regarded as feasible in the Wynaad. The general opinion is that it could not be successful, and would only be a throwing away of money, which alas! is none too plentiful amongst us now-a-days. Liberian coffee is now decidedly, first, favourite. There can be little or no doubt that in vigour and general hardiness it very far exceeds Arabica. The thickness of its leaves apparently defy the fungus; and it is as hearty as an evergreen all the year round. In fact, it is overgreen. The masses of crop do not seem in the very least to affect its lusty growth, and the fact that the blossom sets in one day, is greatly in its favour. No one but a planter knows the heart-sick feeling caused by the drooping downfall on open blossom, which is so often to be witnessed in the case of the Arabica flower.

A very great deal of Liberian is being planted in this district. It has the disadvantage of course of being longer in reaching maturity, but if we can hold on with our remnants of Arabica until the Liberian comes into bearing, we may hope for better times before us yet. There is much depression felt on account of the shockingly bad price given us for last season's cinchona bark. A great quantity was despatched from the districts in the hope of replacing some of the losses incurred by the failure in our coffee crops. But as ill-luck will have it the sales have proved generally so unremunerative that it is absolutely hardly worth while harvesting our bark. This of course is very rough on us. But we should be used to such disappointments. Unfortunately not being constituted like eels, we find each disappointment comes down upon us more like an unpleasant surprise than an habitual occurrence. A good deal of business is being done in timber, and our magnificent Blackwoods are paying the penalty of their lives for our necessities. This is likely to be an improving trade. Very large quantities of "fancy blocks" are in demand for the Continent, and one thinks with regret of the glorious timber which lay rotting in our fields, or became fuel for our coolies in the good old times, when we sacrificed the most valuable trees, simply because we wanted the land, and had no roads by which to transport the wood to the coast. Certainly we are better off in this respect, and our roads are, some of them, becoming a pleasure to travel upon. Well, we will not despair, as long as Liberian, pepper and tea are left us, though the latter does not as yet make much progress. Everyone seems afraid to begin. Or possibly the cost of the "plant," for such a now

enterprise, may daunt them. Pepper is growing well, and a good deal of it is also being planted and we hope to get a better crop on that as well as on our coffee.

I am afraid this is rather a Peter Grievous sort of letter, but I can cheerfully assure you that we shall all of us get some crop this season, and this, after last year's experience, is no small cause of gratitude for all of us. —*Madras Times*, May 15th.

SOME EVILS OF ACCLIMATISATION.

The evils that have resulted from the injudicious and thoughtless introduction of new animals into various parts of the world can hardly be over-stated. The million of acres desolated by the rabbit in Australia, the infinite amount of damage effected by the sparrow in America (where the bird was introduced as a means of checking the numbers of caterpillars which existed in the trees of the larger cities), and the extirpation of edible birds by letting pigs run wild in the islands of the South Seas, might be regarded as sufficient to prove the evils of ill-considered acclimatisation; but apparently these examples have no effect. An evil is seen in the existence of some noxious animal, and thoughtless persons, without considering the ultimate result of what they are doing, introduce some other animal to check its career—not reflecting for a moment that the remedy they propose may be a hundred times worse than the disease which they attempt to cure. The employment of stoats, weasels, ferrets, &c., for the purpose of checking the progress of the rabbit pest in Australia is evidently one of these short-sighted proceedings. What will be the ultimate result of that action, provided it is successful, may be inferred from the consequences which have followed the introduction of the mongoose into Jamaica, for the purpose of destroying the rats that fed on the sugar-cane and other agricultural produce. The tropical climate of this island, the nature of the country, the variety of food which it is able to obtain have been favourable to the reproduction of the mongoose, which now exists in Jamaica in large numbers. Much may even be said in favour of this animal. It has cleared the island of snakes (harmless as well as poisonous), and it has extirpated the rats from the sugar estates. Nevertheless, the mongoose has come to be regarded as an intolerable curse, not only to the settlers and planters, but to the people of Jamaica as a whole. Jamaica used to be celebrated for certain table delicacies that existed in a wild state. Guinea-fowl were introduced from Africa some two centuries ago, and for 150 years have been regarded as *ferre natura*. They laid their abundant eggs on the ground, and consequently have been exterminated by the mongoose. The large pigeons which held a foremost place amongst the native delicacies of the island are gone. The edible land crabs that were found in legions at a certain season of the year are now as rare in Jamaica as they were at one time plentiful. These are some of the results of the importation of the mongoose into Jamaica; but worse still remains to be recorded. The whole of the fauna of the country is being affected by this noxious animal, which was introduced with the idea that it would act beneficially.

The manner in which the existence of one animal acts on another was curiously evidenced when Darwin proved the connection between the existence of the humblebees and that of old maids. The nests of the humble bees are apt to be destroyed by field mice, which in their turn are preyed upon by cats, and cats are encouraged by ladies who are not occupied with the cares of maternity! in this way the chain of protection, which extends from old maids to bees, is traced—the latter being more frequent near human habitations than in districts where field mice are unchecked by the presence of cats. A similar untoward result has occurred in Jamaica, which at the present time is said to be suffering from an intense plague of ticks and grass lice, that abound in hundreds of thousands, and are found on every blade of grass, leaf, and twig in the rural districts of the

island, outailing an immense amount of suffering on man and beast throughout the colony. This plague is due to the introduction of the mongoose, which, having destroyed the ground lizards and well-nigh extirpated the insectivorous birds that used to prey upon the ticks, has given rise to the increase of this terrible annoyance. So great has been the damage done by the introduction of the mongoose that during the last session of the Legislative Council a commission was appointed to devise means for its extirpation. They examined witnesses from all parts of the island. They presented a report to the Governor, which was placed before the Legislative Council, and they suggested that a bill should be passed for the protection of the country from the ravages of the mongoose, which, as it was introduced by the Government with a view to the destruction of the rats in the sugar plantations, should, it is contended, be extirpated by the same authority now that it has become an intolerable nuisance and pest. The committee suggested that three half-pence should be offered for the skin of every male, and three-pence for every female mongoose—a reward regarded as sufficiently high to induce the negro peasantry to purchase traps, and to encourage their ardour in the work of exterminating this savage animal throughout the whole colony. A feeling of intense irritation and dissatisfaction is said to be imminent, unless the Government adopts some measures for destroying an animal, the introduction of which has produced such an infinite amount of harm to the colony. The enormous amount of evil that has been effected by the thoughtless introduction of animals, usually with the most beneficial intentions, into countries where they did not previously exist, should cause all would-be acclimatizers to consider well what may be the ultimate, as well as the immediate, effect of introducing new species into countries where they were previously unknown.—*Field*.

CINCHONA CULTIVATION.

TO THE EDITOR OF THE "MADRAS TIMES."

SIR,—Baron J. Von Rosenberg in his interesting letter appears, by his remarks, to miss the economy of the question. It is all very well to say that bad prices necessitate close planting and inattention to soil, but the question is which method is more lasting? There is no sound argument in saying (assuming Baron Rosenberg so intends) that his methods give quickest returns, unless he can prove they also insure reasonable permanency. From observation, elsewhere, I doubt it. From nature's laws it seems practically impossible. How can any soil, even with manure, maintain to best advantage 2,000 trees to the acre? A strong Cinchona tree is surely a more permanent investment than an attenuated strippling? Planted 4 by 4 when ten years old are little else than the latter, they do not thicken in stem satisfactorily after six years; thorough thinning might aid, but still the soil has had a great deal to sustain, and to honestly reduce the number by one half is a practice that the hard-up planter intensely dislikes. If liable to ailments, the strong grown tree is at least more likely to recover, if not to avoid them. It is no advice to a young planter to hear what the best soils for cinchona can achieve for 3 or 4 years. If North Travancore men can continue to strip 2,000 trees to the acre for 8 or 10 years, then they are in a happy position, for the value of bark is tolerably sure of advance, nor is there any doubt now as to the quality these forests produce. It is the best perhaps in the world. The forests run from 5,500 feet down to 2,000. Suited admirably for cinchona, tea and coffee, it is a mystery why that Goshen has been so little touched.

A beginner must judge for himself between the champions of various methods. May he however, avoid the fatal error of starting an estate too large for his capital, and always bear in mind that more than half the failures in India and Ceylon are due to the fanciful theory that soil can maintain products without the thorough attention required and admitted in every other country.

SOURCED.

THE CEYLON TEA ENTERPRISE IN
RUSSIA.

It is evident from the tenour of the letter addressed by Mr. Rogivue to the Secretary of our Planters' Association that the task to which he has addressed himself—that of introducing our teas into Russia—is to be no light one, nor can his object be obtained apparently without a further outlay of a considerable amount.

But both these facts were doubtless foreseen to a very great extent, when he was commissioned to undertake the work. We feel every confidence that, onerous as his appeals may be, our Tea Committee will not be discouraged by what he writes, or remove their hands from the plough in consequence. He had, however, hoped that the marked falling-off in the character of the China teas imported into Russia would have more readily disposed, than appears to be the case, the numerous tea-drinkers of the latter country to welcome the alternative now offered to them. But it could not but be an uphill task to change the tastes formed during the long period which must have passed since the caravans from the north of China first carried the teas of that Empire across the steppes of Siberia to the great Russian market of Nijni Novgorod. Since that trade commenced the Russians have ever been known as the tea-drinking people *par excellence* of Europe. Coffee has never had such a footing among its peasantry as it has acquired in France and other Continental countries. Tea is the national drink, and hitherto that of China has had undisputed sway over the popular taste. We can therefore feel no surprise that Mr. Rogivue has difficulties greater even than were anticipated to contend with, or that the progress that he is as yet able to report is but meagre. That gentleman appears to hope great things from the opening of the kiosk of which his letter makes mention at the forthcoming French Exhibition to be held in Moscow. Of the intention of holding this Exhibition we had not previously heard; but from what Mr. Rogivue has written it promises to prove a great success, not fewer than one million visitors to it being anticipated. In this respect, therefore, the antagonism between Germany and France promises to bear fruit for this Colony. It is to the *rapprochement* between Russia and France that the success expected for this new Show is due, the Tsar apparently being desirous that the large amount of support to be given to it should proclaim the existing *entente cordiale* between himself, as the representative of all the Russias, and the French Republic.

The amount asked for by the Ceylon Commissioner for his venture at Moscow and in connexion with this Exhibition is a large one, no less than £5001. But we should, perhaps, look upon the application made for this amount more in the light of the desire for a guarantee than as being the amount which it is foreseen will be really required. The rent to be paid for the kiosk for the sole exclusivity of Ceylon tea during the whole term that the Exhibition is to remain open is but £200. Doubtless, we should say, to that initial expense will have to be added the cost of erecting an ornate building, and probably an effort will be made to increase its attraction by the presence of a staff of Sinhalese attendants such as added so greatly to the appearance of the Ceylon

Courts at South Kensington, at the great Paris Exhibition, and at other places. We know the charge incurred for this particular feature on those occasions was necessarily large; but we believe it to have been wisely incurred; and to have yielded a compensatory return, if not in direct at least in indirect results, by making the produce of our tea estates more fully known and consequently more fully appreciated.

Mr. Rogivue complains of the apathy, if not of the direct antagonism, shown by the wholesale dealers in Russia. This may, we think, always be looked for on the occasion of any attempt to divert the channels of wholesale trade. If successful, such an attempt must always have the effect of disturbing existing arrangements, alterations to which cannot but involve a large amount both of trouble and cost. Should, however, popular taste in Russia declare for Ceylon tea, opposition in such quarters must soon be overcome, and we notice that our Commissioner writes of the useful aid afforded towards such an end by the late visit of M. Popoff to Ceylon and by the exertions he has subsequently made in London and St. Petersburg. We shall not presume to dictate to our local Tea Committees what answer should be given to Mr. Rogivue's present application; but it seems to us that, at any rate, a certain amount of further outlay may be made productive of good results.

Just as we are closing these remarks, we find in the *American Grocer* an account of "Tea and Tea Drinking in Russia" in connection with the "Fair at Nijni Novgorod" from which we quote as follows:—

The Chinese quarter has a queer look, its houses being all built with projecting roofs, with bells at the corners, and covered with yellow paint and gilded characters. Here are to be found the offices of the great tea merchants with their sampans, the warehouses filled with vast stores being on the Siberian quay. Tea is the great staple of the fair. Iron and silks and cotton and Caucasian goods have a large place in the Market, but in spite of the supply by water of Canton tea, the *Kiashta* which comes six thousand versts overland, and takes eighteen months in transit still rules at Nijni. We visited a tea merchant and sampled his tea. It is packed in a case of lead, which is protected by a papered wooden chest, which is again packed in a strong cowhide covering with the hair on. Our shopkeeper had the cowhide covering unfastened, and then with a long steel nager in which there were an oblong groove and a very sharp point, he bored into the centre of the chest. When pulled out the groove of the nager was full of tea. A professional buyer tests the tea by rolling the leaves in his fingers and then smelling them; sometimes also he chews a few leaves. We preferred to take our little package to the hotel, and we found it a deliciously flavored black tea. The cost was less than half a dollar a pound.

Tea drinking is the universal habit in Russia. My guide in the Adirondacks could never build his fire in the morning till he had taken a "chaw of terbacker;" and Suliman upon the desert was good for nothing before his coffee and pipe, so my Russian servant, like all his countrymen, swallowed hot tea as soon as he awoke, and repeated the act a dozen times a day. Tea houses are as common in St. Petersburg and Moscow as "saloons" are in New York and Chicago. The "samovar" is the household god, and no peasant is so poor as to be without one, though he may be destitute of shoes and have no clothes besides those which are upon his body. There are forty makes of samovars in Tom's shop, and six thousand are sold in Nijni every year. The samovar is a large urn made of brass or copper, with a tube running through the centre, in which charcoal is placed and lighted. This burning charcoal, like the sacred fire in the Jewish temple, is never allowed to go out, and hence the water around the tube is always hot. The teapot stands upon the top of the samo-

var. A scoop of tea is put in the teapot, the boiling water from the samovar is turned upon it; the infusion is instantly poured into a glass tumbler, and a slice of lemon or a lump of sugar is used as a flavoring by those who like it. The majority of Russians use neither. At all the railway stations, in all the streets of the towns, at every hour of the day and night, "chai" was to be had, even though brand or beer might be wanting. The man in our party who thought tea was only fit for old women and would not drink it, learned, after paying three rubles for a bottle of ginger ale and making himself ill with poor coffee and bad water and worse wine, to swallow the national beverage without a grinace, and almost to like "the cup which cheers but not inebriates," before he left the dominions of the Tsar. On the Siberian wharf, where the sturdy Tartars were unloading the myriads of barrels which brought goods to the fair, there were, by idea thousands and thousands of chests of tea, bales of cotton by the mile, heaps of hides and skins, carboys of acid, casks of dried fruit, and mountains of iron from the Ural. Wool is a great article of commerce at Nijni—we saw enormous heaps of the fleeces of sheep, and in the Bazaar some of the famous Ukraine wool. They have timber too, and stone, and bronze, and carts and all their separate parts, and in fine, all things which men can use, or wear, or eat, or drink. Among these last articles were literal hills of watermelons. Every man, woman and child in some parts of the town seemed to be eating watermelons. Could a Southern negro have dropped into Nijni during the fair, he would have thought himself in paradise, for the delicious fruit was everywhere, in heaps on the wharfs, at the markets, in wagons, and apparently in the hands and the mouths of most of the two hundred thousand strangers who are said to flock hither in August.—*Editorial Correspondence of the New York Observer.*

CEYLON PRODUCE ESTIMATES AND PROBABLE CROPS FOR 1891.

TEA.

Early in the year we endeavoured to collect such estimates from the several planting districts in reference to staple products as might enable us to judge more accurately of the total outturns. But from certain—especially the larger—districts, the returns were so imperfect as to make a compilation of them not worth the labour required. In other cases, we were greatly obliged to friends who put themselves to a good deal of trouble to afford the required information. Although therefore the figures are of no use for enabling us to indicate a more correct estimate of the total outturn for the island, yet the gentlemen concerned, and other district residents, may be interested in seeing the returns made up for certain districts some five to six months ago as a means of comparison with the position and prospects at the present time. For instance we had careful estimates compiled for the North-eastern group of districts and the total crop of tea for 1891 from Kelabokka, Knuckles, Rangala, Nitre Cave and Medamaharuwara was given at 3,325,000 lb. (Kelabokka 1,175,000; Knuckles 950,000; Rangala and the rest 1,200,000 lb.) We suspect if the estimates were to be made up at present that the total would be nearer 4 than 3 million lb. Matale East (with Laguala), North and West were put down for 2,100,000 lb.; but we were without full returns for Ekalawa, Hunasgiriya and the famous Valley included in Wattegama. It is the opinion of one who may almost be called an old "Ceylon tea planter" that the long "strath" or succession of "straths" (valleys) from Matale to Peradeniya and

thence up via Gampola to Nawa'apitiya will prove to be the richest yielding portion of the country in tea. The district of Dolobage which always stood well in the palmy days of coffee, has also been one of the earliest to take up with tea which luxuriates in its climate and soil, so that the estimate for this district alone at the beginning of the year (3,100,000 lb.) was nearly equal to the outturn from the whole of the North-eastern group of districts specified. We suppose 4 millions lb. would be about the estimate for Dolobage, Kaduganawa and Alagala, but this is doubtless below the mark now. Farther up, while we got 1,600,000 lb. for Kotmale and 2,200,000 lb. for Lower Dikoya, we were left to conjecture Ambagamuwa at about 1,200,000 and for Yakkessa some 600,000 more, making for this group, a total of about 5,600,000 lb. If we now go to the Far East, we get the crop for Hewaheta Upper estimated so closely as 814,000 lb. and Hewaheta Lower 613,000 lb., while for Hantane our return is imperfect but, we suppose the total will be about a million lb., while Nilambe is placed at 900,000. Gallaha Factory serving several estates in this quarter cannot be putting through this year less than half-a-million lb. We thus have 3,300,000 lb. for the Eastern group. For Pussellawa, Ramboda and Punalawa our returns in estimates were very imperfect, so that our reckoning of an outturn of about 2 million lb. of tea can only be considered approximate. We omitted while in the North, to credit 120,000 lb. to Kurunegala, and if we add 1½ million for Hunasgiriya and "straths" not otherwise counted, the grand total for country between Matale and Ramboda and Hewaheta, and Yakkessa, becomes very nearly 22,000,000 lb. or probably above one-third of the total export from the island for the year.

Above we give estimates for all the Northern and what may be called the Midland districts, and we made the total outturn this year as nearly as possible 22 million lb. for all the country extending from Matale to Ramboda and from Hewaheta to Yakkessa. Now if we turn to the three extensive higher districts—Dimbula, Dikoya, and Maskeliya—we find, curiously enough, that our reckoning of the aggregate crops of all three divisions, comes singularly near the above result for the older districts. In July 1888, these three districts were returned as having 57,000 acres of tea planted, and between that date and July 1890, the addition to the planted area was 18,000 acres. Altogether, then, we cannot put the tea crops of the three districts for 1891 at less than 19,500,000 lb, while they may amount to 22 million lb.—We have next the Nuwara Eliya division which may be said to include Maturata, Udupussellawa, Kandapola, New Galway and Nuwara Eliya itself. For Maturata our estimate is a crop of from 900,000 to the round million lb.; for Udupussellawa we get about 1,300,000; for New Galway about 100,000 lb.; Nuwara Eliya and Kandapola say 730,000 lb., making a total of very nearly 3 million lb. If we now go to Uva proper, but shorn of its outlying divisions of Udupussellawa and New Galway, our estimates—furnished very kindly by competent local residents who took a good deal of trouble to complete them, run:—

Haputale ..	1,385,000 lb. Tea.
Madulsima &	
Hewa Eliya ..	566,000
Monaragala ..	17,000

To these we have to add for Haputale West, say 250,000 lb., and for Badulla which we are inclined to put down, in correspondence with the above, at a little over one million lb., but suspect that all these estimates will prove well on the safe side and that the aggregate from Uva this year cannot be less than 3½ million lb.

We now turn to the Kelani Valley and the lowcountry generally. A return sent round the premier lowcountry district was only imperfectly filled up; but adding in for the estates left blank as well as our means of information will permit, we get a total outturn of 5,527,300 lb. and we fancy that the six million lb. will be sent away. Again for the Kalutara district, the estimate furnished to us is for 1,750,000 lb. which will also no doubt prove below the mark. For Balapitiya and Ambalagoda we got an estimate of 155,000 lb.; for Udugama and the rest of the lowcountry, we suppose we may add a million lb. giving a grand total for the lowcountry *par excellence* of about 9 million lb. We have still the Balangoda, Kuruwita, Rakwana, Kukuln and Morawak Korala tea estates to take into account. The estimates furnished to us, were as follows:—

Balangoda	...	345,000	lb.
Rakwana	...	900,000	„
Kuruwita	...	80,000	„
Kukuln Korala	...	300,000	„
Morawak	„	700,000	„
Total ... 2,325,000 lb.			

We find one omission in not allowing for some 700 acres of tea in Kegalla and Polgahawela which may bring the above up to 2½ million lb.

We may now attempt a summing-up of our divisional figures as follows:—

Northern and Midland districts	..	22	millions.
Dimbula, Dikoya and Masketiya (say)	21	„	„
Nuwara Eliya Division	..	3	„
Uva	..	3½	„
Kelani Valley, Kalutara and low-country generally	..	9	„
Rakwana Group	..	2½	„
Grand Total	..	61	„

It is interesting now to contrast these figures with the estimates offered at the beginning of the year for the whole island:—

Mr. H. K. Rutherford's	..	52,750,000
Mr. A. E. Scovell	..	54,000,000
Mr. R. Porter (max. 57, min. 53)	..	55,000,000
Mr. W. Mackenzie	..	54 to 56,000,000
Ceylon Observer	..	56,000,000
Mr. C. Armstrong—over.	..	56,000,000
Mr. W. F. Laurie (max. 60, min. 56)	..	58,000,000

To this we may add the fact of shipments up to 18th May reaching to nearly 26 millions, pointing to a total for the year of not less than 63 to 65 million lb. Of course long-continued unfavourable weather during the present and next monsoons may make a difference and cause a considerable falling-off in shipments; but judging by the experiences of the past four years, we most fully expect to see today's detailed estimate of 61 millions exceeded by the total shipments of tea for 1891.

As regards the future, we can only at present lay the following extract from the letter of an experienced planter before our readers, and we believe there is enough in it to cause serious thought to all interested in "Ceylon Tea":—

"Were I able to spot one block of land similar to Mariawatte's original 100 acres, I would have bought it any time within the last seven years, for I have been all that time looking out for it! Mariawatte had never grown coffee as all such land at average elevation had done, which was not often done. In Dimbula and Dikoya, I believe there are 20,000 to 30,000 acres, which, if planted originally in tea, would have given 800 to 1,000 lb. per acre. In the older districts, there is a similar area which under the same circumstances would have given 1,000 to 1,200 lb. per acre. Some virgin land

in the highest part of Kelabokka or East Matale is now giving over 900 lb. per acre. Ukuwala neighbourhood can be worked up to this yield. Tea is not yet in full bearing in these coffee districts; but already we hear of fields, nay whole estates, giving 480, 500 and 550 lb. per acre, and of one, from which 600 lb. are expected. With cultivation and manuring even to a small extent, I believe 40,000 to 50,000 acres in the coffee districts, would average 600 lb.—the best 10,000 acres giving 800 lb."

This means that 50,000 acres of our best tealand are to yield 32 million lb. ! What then are we to put down for the other 200,000 acres? Certainly not less than 75 millions, so here we are face to face in a very short time, with a possible export from the island exceeding 100 million lb. Who would plant more tea in Ceylon after this?

COFFEE—COCOA—CARDAMOMS—CINCHONA BARK.

In our notice of the Estimates and probable Crops of other Products—apart from Tea—our remarks may be very brief at this time. Tea has become of such overwhelming importance in the planting enterprise, and the acreage under other products is so comparatively limited, that there is not room for much discussion or speculation about district returns. First of all, we may give the estimates of two experienced Visiting Agents in respect of the Export of COFFEE during 1891:—

	Maximum.	Minimum.	Probable
	Cwt.	Cwt.	figures.
Estimated ...	60,000	50,000	55,000
Do. ...	100,000	80,000	90,000

Here there is a wide discrepancy; but judging by a certain number of carefully compiled district returns we think it will be safe to take 75,000 cwt. as the probable outturn. This would include some 22,000 cwt. from Haputale, and perhaps 20,000 cwt. from the rest of Uva. Of more immediate interest is the return of shipments to date as contrasted with the rest of the year, thus:—

COFFEE EXPORTS.

	Up to 25th May.	Rest of year.	Total.
1891	.. cwt. 35,471 (say)	40,000 (say)	75,471
1890 48,945	37,000	86,000
1889 32,276	56,000	88,082
1888 72,781	67,000	139,663

At present there are heavy pickings of crop in Haputale and it will be disappointing, if our moderate estimate is not realized.

As regards COCOA or CACAO, two estimates for the island before us come a good deal closer than in the case of the estimates for coffee, namely,—

EXPORTS OF COCOA IN 1891.

	Maximum.	Minimum.	Probable.
Cwt.	18,000	16,000	17,000
„	17,000	14,000	15,000

A detailed estimate for a large proportion of the districts adds up to 12,230 cwt. (including 7,000 cwt. for Dumbura, 2,500 for Kurugogala, 1,000 cwt. for Matale North and 780 cwt. for Mouragala) but about one-fourth of the acreage is unrepresented and that would lead us to place the estimate at about 16,000 cwt. Here again, however, is the comparison between shipments to date and the total for four years, pointing to a probable export for 1891 up to, if not in excess of, the highest estimate! How is this accounted for?

EXPORTS OF COCOA:

	Up to 25th May.	Rest of Year.	Total.
1891	.. lb. 11,388 (say)	6,000 (say)	17,388
1890 8,588	7,400	15,988
1889 7,535	11,500	19,051
1888 7,641	5,500	13,159

We now turn to CARDAMOMS and the Visiting Agents here again differ greatly:—

EXPORTS OF CARDAMOMS FOR 1891.

Maximum.	Minimum.	Probable
lb. 360,000	820,000	310,000
lb. 270,000	230,000	250,000

But here we find certain district returns aggregating no less than 451,950 lb.—the district of Kanganala (including Medamahauwara and Nitre Cave) alone being put down for 300,000 lb. (?) Matala East 75,000 lb., Hewa Ieta Lower 37,000 lb., Dolosbage 10,000, Haputale 6,000 lb., Kurunegala 9,500 lb., Kelebobokka 5,500 lb. An extent equal to one-fourth of the whole area planted, is not estimated for, so that would bring the estimate up to 560,000 lb. an outrageous figure. Looking at the shipments, we think far too much was put down for the Kanganala group of districts, and we do not think the total export for the year is likely to exceed 340,000 lb., thus:—

Up to 25th May.	Rest of Year.	Total.
1891 ... lb. 139,895 (say)	200,000 (say)	339,895
1890 ... lb. 163,719	224,000	387,719
1889 ... lb. 142,910	219,000	361,910
1888 ... lb. 116,904	141,000	257,904

Lastly, we have CINCHONA BARK estimated by two planters, with the same result, curiously enough, as follows:—

Maximum	Minimum	Probable.
lb. 8,000,000	5,000,000	6,500,000
lb. 7,000,000	6,000,000	6,500,000

One of the estimators appended the following note to his estimate:—

"Cinchona will, of course, be influenced by the market. A strong market would, naturally, throw a lot into the market; a weak price will keep it out." Our district returns, strangely enough, only make up 1,835,000 lb. of which 80,000 lb. (mostly fine Ledger bark) were to be from Nilambe, 450,000 lb. from Haputale, 250,000 lb. from Madulsima and Hewa Eliya, 22,000 lb. from Monaragala, 60,000 lb. Matala East, 80,000 lb. Kotmale, 65,000 lb. Kelebobokka, 34,000 lb. from the Hewaheta, 40,000 from Dolosbage, 32,000 lb. from Alagala, 10,000 lb. from Balangoda; but we had no estimates from Badulla, Udapussellawa, Dimbula, Dikoya or Maskeliya. It is specially interesting under these circumstances to see how shipments and totals compare:—

Up to 25th May.	Rest of year.	Total.
1891 ... lb. 2,051,542 ... (say)	3,400,000...	5,000,000
1890 ... lb. 3,490,574 ...	5,250,000...	8,740,574
1889 ... lb. 4,108,943 ...	5,180,000...	9,288,943
1888 ... lb. 4,647,379 ...	8,000,000...	12,647,379

Of course "if the market improves," our probable 5 millions may expand into 6 or 7 million lb. —It is of interest, to see in connection with the careful detailed estimates kindly sent us for the Madulsima and Hewa Eliya district, that "rubber" 7,000 lb.), "tobacco" (200 cwt.) and "pepper" (re among the minor products likely to be exported thence.

COFFEE IN JAVA, CEYLON AND MYSORE.

Mr. R. H. Elliot, the well-known Mysore estate proprietor, and author of the "Experiences of a Mysore planter," writes to us enquiring as follows:—

"Could you tell me if Dr. Trimen found that coffee in Java is suffering much from leaf disease? I infer that it is from the introduction there of Liberian. I ask because I am preparing for a new edition of my "Experiences of a Planter," which was published 20 years ago. I shall have much to add *in re* coffee, gold, &c. I hear bad accounts of leaf-disease from planters on and near the hills, and also from Coorg. I really believe that Mysore is the only coffee coun-

try that will hold out, and it will do so because coffee can be treated there as (or what it is in nature) a shade plant, and because the dryness of the climate in our long rainless season is unfavourable to the disease, which by the way we have always had, in all probability for nearly 100 years. Then Mysore is in the same latitude as Abyssinia, the original home of the plant, and I am told that it is generally found that plants do best if not taken out of their native latitude. Ceylon is out of the coffee latitude."

Dr. Trimen did not travel much in the coffee districts of Java; but undoubtedly *Hemiteia vastatrix* some years ago did nearly as much mischief to ordinary coffee in Java as it did to it in Ceylon and the greater part of Southern India, and that is one reason why Java and Straits planters have taken to Liberian coffee. As regards Mr. Elliot's remarks on Mysore and Ceylon and his reason for the continued successful cultivation of coffee in the former, we cannot help thinking his idea is rather fanciful. Mysore has good soil and a climate which permits culture under shade. That is the reason, we suspect, why coffee suffers less (for it certainly does suffer) from leaf-disease, than in other parts of Southern India and Ceylon. We notice, however, in the statistical returns just published by the Indian Government that Mysore has still 123,250 acres under coffee (Hassan division 49,000 acres and Kadur over 74,000) against 62,465 acres in Coorg; 55,618 in Madras Presidency; and less than 50,000 acres in Ceylon. In 1886, Mysore was officially reported to have 131,149 acres under coffee; Coorg 71,994; and Madras Presidency 93,873 acres. Java and Sumatra are still credited with a large area under coffee, perhaps 300,000 acres, but how much of this may be 'Liberian' it is hard to say. The export of coffee from Java alone after reaching its lowest point in 1887 (263,000 cwt.) has begun to increase again, the half-million cwt. being nearly reached in 1889.

LABOUR SUPPLY AND COAST AGENCIES FOR COOLIES.

We have not the slightest faith in the success of an agency on the Coast for the supply of coolies for Ceylon plantations. All experience in the past has shown the utter futility of any such attempt to meet the varied, the multiplied and conflicting requirements of planters. Even if all the proprietors of the island joined to support a special fund for the establishment of such an Agency, we should anticipate nothing but disruption, failure and a winding-up within a twelvemonth. It is when the details of working out such a scheme come to be considered that the difficulty begins; and in conjuring up a Coast agent with 50, or 100 or 500 orders for coolies from planters eager to get full value for their money, and jealous of priority, while in urgent need of reinforcement, we can readily realize how the trouble would arise. As well try to work all the plantations in Ceylon from one joint "Upkeep Fund," as get coolies supplied through a Labour Fund and Cooly Agency, in our opinion. On the other hand, we have no objection to giving some extracts from the letter of a planter who is a strong believer in a Cooly Agency as follows:—

The idea of a cooly agency is nothing new. I believe: one was tried before, and proved a failure, but that is no reason why it should be a failure if thoroughly considered and carried out. In a few days P. A. meetings will be held all over the planting districts, and the opportunity should not be lost to bring this important matter up for discussion. There is nothing of more importance to estate managers than

a good and sufficient labor supply. With an insufficient labor force on an estate, weeding contractors get careless and fall behind with their work; coolies refuse to, or declare their inability to, do a fair day's work, and the daily out-turn of a small labor force is less in proportion to the number of coolies on the estate than when the force is sufficient. A manager so feels his position at stake, and the serious consequences arising from an insufficient labor force, that it becomes very hard to do to others as you would others do to you in the matter of coolies. It requires no argument to prove that an insufficient labor supply is frequently the cause of loss of crop, coarse plucking and neglect of cultivation, and experience has taught many that unless estates are in the immediate neighbourhood of Sinhalese villages it is quite a delusion to hope for aid from the Sinhalese.

"I believe several thousand more coolies could be procured for service in Ceylon if all the advances sent to the Coast were used for that object. At present probably not one half our money so sent is given to the coolies. Under the Labour Fund Committee scheme, we would know exactly how many coolies to expect for the money issued, and only managers or agents of estates who contributed to the Labor Supply Fund would be entitled to indent through the Secretary for coolies for their estates." Of course, all are agreed as to the importance of a sufficient labour supply; the point is as to the best mode in which it can be procured.

TEA:—FOOCHOW NOTES.

(*Foochow Echo*, 9th May.)

The opening prices in Hankow are we understand from fifty to hundred per cent dearer than last season! Ningchow Tls. 85 and Oaufa Tls. 63.

It is reported that the price of tea in Pakling is double that of former years; and it is doubtful whether it will benefit the tea growers or the tea buyers, and Foreign buyers will do well to judge the quality which is reported to be of good flavor.

By the end of next week, we understand, a considerable amount of new tea will be down. A lot would have been placed on the market this week had it not been for the bad weather we have had for some time.

TEA FOR THE TEUTON.

The subjects of the Emperor William II. must stand ready. Germany is about to be invaded,—but by a friend. The Indian tea planter has fixed his speculative eye upon the Kaiser, and an organised advance into the country of the bear-king Cambrian is contemplated. So, at least, we gather from the following extract from an English contemporary:—

The tea, which consists of three specially-selected blends is put up in attractive little packets of ½ lb, ¾ lb, and 1 lb. (German weight), the labels of which set forth in two languages the virtues of the contents, and bear, moreover, clearly printed on each, careful instructions for tea-making, together with net weights and retailing prices. The latter we believe, have been fixed at 4, 5 and 6 marks per ½ kilo, which, in Germany, where 6 marks is quite a common price for quite a common tea, should prove an attraction in itself. The services of a Hamburg firm have been secured as a sort of general agency or distributing centre for the German Empire, and we understand that a contract has been entered into for a term of years, which includes several valuable provisions. Among these is one by which the agent agrees to purchase a fixed minimum—and yet not a very small—quantity of the tea in each year; and by another, to establish at least one depot for the sale of the new article in every town of over 20,000 inhabitants, and not less than twenty such depots within the first year.

To Englishmen, who, certainly since the days of Dr. Johnson, have been distinguished as a tea drinking nation, there is something rather funny in appealing to the aesthetic tastes of nearly fifty millions of people by coupling them with "attractive little packets," while the "clearly printed, careful instructions for

tea making" almost constitute a reflection on the laud of metaphysics and Universities. The Germans will be delighted to hear that they are "an eminently teachable people," for this, according to the article in question, is one of their attributes. There is, however, no doubt that the Indian planters are right. The quantity of tea consumed in Germany is annually about 0.09 lb per head of the population. When one thinks of this from a tea planter's point of view the enormity of the offence is at once apparent.—*Madras Mail*.

HIGH-PRICED CEYLON TEA.

WORTH NEARLY HALF ITS WEIGHT IN GOLD
—£25 10 PER LB.

The Indian tea sale-room in Mincing-lane was crowded yesterday afternoon by an eager company. Rarely is so much excitement exhibited there. Not only was every seat filled, but business men were jammed together like sardines, right down the gangways as far as the doors. It was like the pit entrance to a theatre on Boxing night. But the entertainment the crowd had come to witness was to be brief, and not particularly amusing. Nine boxes of "Golden Tip" tea, from the Gartmore Estate, Ceylon, were to be sold by auction, in one lot, at per lb., by Messrs. Gow, Wilson and Stanton. The interest in the proceeding was based on the expectation that the price given would be a high one. A few weeks ago tea sold in Mincing-lane at a little over £10 per lb.; last Tuesday a package fetched £17 per lb. There was an impression that even this high figure would be surpassed, and that anticipation was amply realised.

Mr. Wilson officiated, and immediately he mounted the rostrum someone facetiously cried out, "Sevenpence-halfpenny." There was at once a *bona fide* bid of "ten guineas," followed by a whistling expression of amazement at the magnitude of the start. It was arranged to raise the bidding at least 2s. 6d. at a time, and forthwith there was a cry of £10 12s. 6d. With great rapidity the price was raised £13, £13 10s., £14, £14 10s., £15, sixteen guineas, seventeen guineas, £18, £19, and twenty guineas, after which one gentleman, amid the loud laughter of the company, immediately cried, "Twenty-one pounds," and evidently did not perceive till some seconds afterwards, that he had made an offer equivalent to the proverbial Irishman's rise of wages. Up to this point, the chief bidders had been Messrs. Cranston, of Glasgow (who bought on Tuesday at £17 per lb.), Messrs. Bales, Lapworth and Tyers, Messrs. Jobbins and Co. (all brokers), and the auctioneer himself. The latter was asked the name of his client, but refused to disclose it till the transaction had been completed. The remainder of the bidding resolved itself into a duel between Mr. Wilson and the representative of Messrs. Cranston. Still without any hesitation on either side, bids were recorded at £21 5s., £21 10s., £22, £22 10s. and £23. Then amid cheers, the representative of the Glasgow firm cried "£25." Mr. Wilson at once said "£25 10s.," and the other side for the first time hanging fire, he demanded, "Any advance on £25 10s.?" There was no response, and the hammer fell. It was then announced that the purchaser was the Mazawattee Tea Company, and after raising another cheer nearly the whole of the company dispersed, the remainder of the business exciting comparatively little interest.

In the general sales, competition was even less here than it had been of late, and buyers were indisposed to bid quite up to recent rates, either for Indian or Ceylon growths. Teas over 1 lb were most depressed, and showed in some instances a decline of nearly a penny per lb. Many readers will marvel why, in face of this position of the market, a particular lot fetched the enormous and unprecedented price of £25 10s. per lb. A representative of *The Financial Times* made some inquiries on this point after the sale, and learned that the tea, while of a decidedly superior quality, was procured rather as a curiosity than as an article of consumption. It is valuable because rare. It consists entirely of the tips of the new shoots of the plant, procuring which involves an enormous amount of labour

and the collection of but a comparatively small quantity of which absorbs the shoots of plants throughout a very large area of ground. Our representative was shown a sample of the stuff sold, which looked rather like a tobacco mixture than tea, there being nothing in the nature of the ordinary leaf, but the whole having the appearance of a short-chopped fibre, some of the ingredients being golden, and others of a darker hue. The golden was explained to be the superior article, and a comparison with a sample of what was previously sold at the next highest price justified the advance in the figures, the gold being in far larger proportion in yesterday's supply. We learn that when tea of similar character fetched over £10 per lb. a few weeks ago, the Sultan of Turkey desired to purchase an ounce, which was sold to him for a sovereign, and that to sundry others who take an interest in curiosities of the kind, small quantities were sold at high rates. It is anticipated that in the present case there will be a similar demand in certain quarters, and it is thought probable that the greater part of the lot will find its way to the Chicago Exhibition. We fear that persons who may purchase the Mazawattee Company's tea will not be able to detect in it any infusion of the £25 10s per lb. supply. It will be found on calculation that that price represents nearly half the weight of the tea in gold.

The recent weakness of the tea market is attributed to the heavy supplies coming from Ceylon, the knowledge of which has depressed Indian teas generally, in addition to which the failure of Messrs. Adams and Bell, an old firm of China tea merchants in the City, with liabilities estimated at £200,000, has had a disturbing effect on the market.—*Financial Times*, May 8th.

THE CEYLON AND INDIAN TEA ENTERPRISE.

The Hon. W. W. Mitchell writing to us under date 7th May, says:—"The tea market has given way a little, buyers being frightened apparently at the large shipments of Ceylon tea, the result of the heavy flushes consequent upon the abnormal rains you have had. Estimates of the shipments during April have been anything from 5½ to 7 million lb. and it is a pity that accurate returns are not issued more promptly. I know the difficulty there is in getting steamers' manifests completed, but the Chamber of Commerce might devise means of procuring more expeditiously than at present, information that a good deal of importance is attached to on this side. Mr. S. Elwood May, the President of the Ceylon Planters' Tea Co. in America is here on a visit, and has met the Tea Committee of the Association and impressed them very favourably. The support given by the Planters as a body, has so far been very meagre, as witness the resolution passed by the Association in January last, and he would like more of an 'endorsement' by them. Ceylon should make a good demonstration at Chicago, and it goes without saying that no better channel could be found for doing it than through the Ceylon Planters' Tea Co. I hope the Tea Fund Committee will be liberal when the occasion comes, seeing that they have never given a cent towards the introduction of tea into America."

We give prominence to this information in addition to that in our London Letter, because undoubtedly the great practical question of the day before Ceylon is (1) how to facilitate the sale of her teas in Mingoo Lano, and (2) how to extend the demand in new countries and in America more especially. We may therefore feel certain that the Tea Fund Committee and our tea planters generally will view favourably any proposals coming to them with the approval of the businessmen on the Committee of the London Association, while the Committee of the Chamber of Commerce will no doubt see what can be done to meet

the requirements pointed out by Mr. Mitchell. As regards our Tea industry generally it is evident that many people in the old country are beginning to think that it is not only destined to shut up China, but to beat India handsomely in the race of competition. Our London correspondent brings forward two Companies which he finds reported together in the London *Times* and he makes out that they may be taken as typical and that they show Ceylon is by far the better adapted for a tea-growing country and that our credit ought to rise accordingly. There is something in this and more might be made if our largest Company—and the biggest Tea Company in the world, the Ceylon Plantations Tea Co. with its 15 per cent were quoted in comparison with the largest and best of Indian Companies. We do not say, of course, that so striking a contrast could be maintained in the case of all Companies working respectively in Ceylon and India. Still, we should have no difficulty in citing striking juxtapositions many times over were we called upon to do so. No doubt the coincidence of the quotation by the London *Times* will arrest the attention of many of the enormous number of the readers of the leading journal, and it may fairly be concluded that deductions highly favourable to Ceylon credit will be made upon the facts disclosed. At the same time that public attention has thus been drawn to the superior position occupied by Ceylon as a country wherein to invest in tea cultivation, the succeeding issue of the *Times* contained the announcement of the fact that our teas had been sold in Mingoo Lano for a price somewhat exceeding a guinea an ounce! We, out here in Colombo, can discount the weight of this last announcement. We know very well that it relates to a mere *tour de force*, that the circumstance is altogether outside of practical commercial results. The British public, however, will not be so readily able to recognise this, although the trade must be fully aware of it. Two succeeding issues of the world-read metropolitan journal—along with practically the whole English press—have therefore contained an advertisement of our planing enterprise which must be productive of satisfactory effect. For the generality of people will not stay to consider the conditions under which this and former abnormal prices have been obtained. We have seen how ignorant have been the conductors of home journals as to these conditions, and we may be quite sure that the conclusion of the great majority of those who have read the two announcements referred to will be that, not only does Ceylon grow tea of a value such as has never been heard of, but that the results of a financial kind are close upon three times as good in Ceylon as they are in India!

It is anticipated, at home, that benefit to Ceylon must follow upon this. Home capitalists, have of late been exceedingly cautious in their investments, and they have required strong inducement and very complete assurance to lend money on colonial enterprises. But the sufficient inducement and assurance, it is now thought many moneyed men at home will find in the case of the Ceylon tea enterprise. It remains to be seen whether the further transfer of estates from proprietors working—in some cases at least—with borrowed money, to individual or Company purchasers commanding capital, is likely to follow. There is no doubt still room for amalgamation and the thorough equipment of central factories serving a large acreage. But meantime, anything to strengthen the credit of the staple industry of Ceylon is an advantage and as such we welcome the wide and favourable advertising of our teas and tea culture, this mail presents,

CEYLON UP-COUNTRY PLANTING REPORT.

WEATHER AND LABOUR - TAMIL LETTERS AND POSTAL AUTHORITIES—SCOTTISH IMPERIAL INSURANCE COMPANY AND TEMPERANCE—A LITTLE GIRL'S SIMPLICITY. May 25th.

At present one has little else to think of than the weather. It is in evidence everywhere, outside and inside, and its effects are visible in leaf that won't wither, short musters in the morning, roofs that will let rain through, clothes that don't dry, boots that will grow fungus, and general discomfort and unpleasantness. Work falls back and back, for when an estate has barely enough of coolies to get on with in normal times, to have the added horror of the wind and the rain fighting against you is a serious handicap. Still, with it all, it is wonderful how things are kept straight.

We are all in hopes too of reinforcements to our labour force, for you hear of the coming of the new gang, long before they put in an appearance: and some of us would even willingly see a slaking off of flush—high treason though the thought may be—just to get our feet cleared and wipe off arrears of work, and then begin again.

How is it that Tamil letters get so often miscarried? So long, of course, as the letter reaches, Rama Sami carees not, as a rule, whether a week or a month has been lost in the transit, and if the letter disappears altogether and he hears that one has been written, he would be the last to blame the postal authorities. He would treat the story of the writing rather as a romance. It is a wonder to me however what little care these coast letters get. One comes up in your tappal box, every now and again, which should never have been sent, as it is intended for another estate altogether. It makes the round of the estates' kanganies, and goes back after some delay to the Post Office as a derelict, to wander away, after that goodoess knows where. Very likely shoved into the first handy tappal box to try its luck there, and as likely as not a blind shot again. Of course the Tamil address is often a thing of voluminous vagueness and it would need an inspired genius always to hit on the letter's destination. Still so many Tamil letters intended for some estates find their way into the wrong tappal box, that one is impressed with the idea that a little more care and attention would result in better delivery. The knowing ones who go to the coast carry away with them properly addressed envelopes, as I suppose they find that the English characters have more respect paid to them than is usually awarded to the Tamil ones, and are sure.

I have received a copy of the prospectus of the Scottish Imperial Insurance Company of which Mr. W. D. Gibbon is agent. This Insurance Company has a provision, which I am not aware that any of the other Companies represented in the island has; that is a separate section open for abstainers. The prospectus says that "The profits earned from the premiums of such assurers are ascertained separately, so that abstainers have the full benefit to be derived from such a classification." The prospectus gives no hint as to what this advantage amounts to; being a comparative young office, it may not yet feel justified in tabulating its already ascertained results; but other offices do. Perhaps the oldest company that has subdivided its lives in this way is the United Kingdom Temperance and General Provident Institution; and over a seventeen years period, the deaths in the general section were but eighty below the expectancy, whereas in the Temperance section a little over seventy per cent were all that died. This of course means a very considerable bonus to the abstainer and those who go in for insurance and who are ab-

stainers should see that the advantages of the longevity of the class to which they belong are wholly secured to themselves.

The "Scottish Imperial" still sticks however to an extra ten shillings per annum for every £100 assured as a Ceylon risk. No doubt Assurance companies are slow to move in matters of this kind, but that there should be an extra risk for Ceylon, shows either a grasping disposition, or an inacquaintance with the conditions of Ceylon life. When we have Companies at home open to proposals without a medical examination at all; and others which allow residence abroad at the home rates, the Companies that trade with Ceylon ought not to be behind the foremost. That life has more risks here than it has in the old country is very much open to doubt; indeed it is all the other way if anything like ordinary care is observed. In due time this will come to be recognised, and it is for local men like the agent of the "Scottish Imperial" to press this fact on his Company's directors, so that extra premiums which cover fanciful risks, may disappear, and the Ceylon insurer may have his business done on the best terms.

A little five year old girl was having a story read to her the other day, when the sentence occurred, "And his eye fell upon the page." "Did it really tumble out?" was the question she immediately asked.

I began my letter with the weather, and am constrained to end it with the same theme. There is a good deal of monotony in it, and the constant rain gets very tiring. We will all be pleased to see a change which would suit planter and cooly alike, and give something brighter to write about.

PEPPERCOON.

THE SCOTTISH CEYLON TEA COMPANY.

Mr. H. L. Forbes report on his recent trip to Ceylon to his Company's Board is mainly as follows:—

The Board called upon me to make no special report on any particular estate or possession of our Company. If, however, I had considered such necessary, I should have done so, but I have pleasure in stating that I could furnish no more elaborate or truthful reports on the Company's interests in Ceylon, than those supplied us by our Ceylon Manager, so, therefore, merely take the Estates generally. In company with Mr. Kerr, and the respective Superintendents, I have inspected each and all of the Company's properties in the island, and can corroborate Mr. Kerr's reports furnished to us from time to time thereon, in every detail. From my intimate knowledge of all the estates I was in a position to notice progression or otherwise. In everything I saw I could mark much improvement in growth, and nature has been assisted by the most careful husbandry. The Company's properties, during the two years which the Company has held them, have immensely improved in value, not only from their natural increase in age (being young when purchased), but from the judicious care bestowed upon them, the capital put into them, and the generally improved prospects of Ceylon as a Tea producing country, and I think it is universally acknowledged, by those who ought to know, that the yield of up-country estates, such as ours, will be considerably greater than was ever anticipated.

As this date, I have every reason for stating that I consider the Company's properties have increased in value to the extent of 30 per cent on the price at which they were acquired by the Company two years ago. Ten per cent was put into them in hard cash by the shareholders themselves at our general meeting of 1890, and quite 20 per cent has been added to them during the two years of possession, by circumstances over which we had and had not control.

Estimates of 1891.—I have gone into these with Mr. Kerr, and on the aggregate see no reason to alter total estimated profits, but much depends on the prices respectively of tea and silver. I think we may be a little too sanguine on the prospects of the little coffee we have remaining on Livery Estate, but this I consider will be made up, by what to me appears to be moderate estimates of our aggregate returns from Tea.

The Quality of our Teas for some months to come, excepting perhaps Livery, I do not anticipate to be so rich as I hope it will prove towards the end of our present year, and this must be attributed to the large amount of leaf, which for a time will come in from what may be called "First Flushes." We have a large area pruned down on all our Estates at present, which has decreased our yield, and will tell on the quality for a few months to come, but will be all in our favour a little later on.

Manuring.—So far as can be judged, our experiments in this line have been a success, and in some instances a great success, for one, a manured field on Strathdon estate has averaged for the last three months considerably over 100 lb of made tea per acre per month. So long as tea keeps at its present prices, exchange about 1861 to 1862, and labour as plentiful as at this date, I should recommend the judicious application of manure to most of the Company's estates, especially Abergeldie and portions of Strathdon.

Forough Circulars, is issued by several Companies in the Island, I do not propose to issue, but would wish that all servants of our Company be always liberally treated with, and on their merits.

Cart Roads to those Estates which do not adjoin each.—I have admitted my strong desire to Mr. Kerr's approval, that every effort should be made to thus increase the value of our properties. I trust before long we may be able to say all our estates are "on" Cart Roads, all are perfectly feasible, and the outlay, in comparison with the advantages, is as nothing.

Government Reserve Forest adjoining Mincing Lane Estate.—This, though only a very small acreage, will, I hope, through the relaxation of Government rules, shortly be added, under certain conditions, to the Estate, and will be of much value.

The Books and Accounts of the Company in Ceylon appear to be kept in a proper and business-like form.

The Relationship between Mr. Kerr and his various Superintendents.—This, a most important feature in the successful working of any group of Estates, seems to be on a very satisfactory footing. All pull well together.

Labour Force appears sufficient for present requirements on all the Estates.

Adelaide Estate.—This property, consisting of some 230 acres, of which 103 are Tea in full bearing, 50 partial, a good 47 forest, and about 25 chena, adjoins the Company's property of Benachie, and is about to be added to the capital of the Company, under the name of "Louch," and at the price of only Rs30,000. The property was inspected and valued by Mr. Kerr, Mr. Blacklaw, and myself, and we were all of one opinion, that the price was extremely low, that there was much development, that it was of great value, as adjoining one of not the least of our holdings, probably supplied a want to Watawala Station, and so on. I determined to possess it for the Company, and I have every reason to believe the investment will prove a very remunerative one to the Company. The Estate gave about 27,000 lb. of made Tea last year, and is estimated at 30,000 this. The 50-acre field has not yet been plucked, which is greatly in its favour.

Timber Trees.—Mr. Kerr and I are both quite agreed that such should be extensively planted—chiefly along road sides—not only on our Company's lands, but generally, throughout the length and breadth of Ceylon's Tea districts, not only for the purpose of supplying a want, already too keenly felt (though happily not by us), viz., fuel, but for the breaking up of extensive areas of one product, and so in a great measure scattering disease, the usual result of over-production of one product.

The Scottish Ceylon Tea Company, Limited, are to be congratulated on holding about 10 per cent. of standing forest to their acreage in tea, and over and above, possess large supplies of sound fuel, and a fair quantity of "sawable" timber on the ground. This, with water power on all our Estates, cannot be too highly appreciated.

I consider a cordial vote of thanks to Mr. Kerr and his Superintendents will again be due by the General Meeting in May.

CINCHONA PROSPECTS.—A planter of "Ledger" weary of waiting for a market for his bark, writes from upcountry as follows:—

"It's a weary business this Ledger, if we had put it all in tea at first we would have been caring 21 per cent before this. When will the Ledger do that? Not, I fancy, until half the world's inhabitants is down with influenza, and it would be a dear dividend at that price. Still we will see. The ups and downs in Ceylon are such that no forest industry should ever say die. We are still in the horrors of the wet season."

AGRICULTURAL PRODUCE.—Under the auspices of the Board of Agriculture, has been issued a statistical report showing the estimated total produce and average yield per acre of the principal crops of Great Britain for the year 1890. A general increase as compared with the preceding year is noted for all grain crops, but a deficiency is recorded in all root crops, Potatoes being as much as 14 per cent below those of 1889. The average yield of Wheat seems to be between 27 and 28 bushels per acre. Hay was also deficient, and Hops likewise. As there was not already sufficient confusion in our system of weights and measures, it now appears that there are "acres" and "flop acres"—a circumstance which has led to some slight error, now corrected.—*Gardeners' Chronicle.*

A NARCOTIC GRASS.—*Stipa viridula* of Triebus, var. *robusta*, is a variety common in New Mexico, and which has a most injurious effect upon horses and sheep who are so unfortunate as to feed upon it. Cattle who have once tasted it, never again do so; but upon strange animals who do not avoid it, it acts as a strong narcotic or sedative. It is as poison to them, especially in the spring, when the blades first appear, causing a "profound sleep or stupor, lasting twenty-four to forty-eight hours, when the animals rally and give no evidence of bad effect." It is widely known, and avoided, by the natives as "Sleepy Grass." We read (also in *Garden and Forest*) that the species *Stipa viridula* is much esteemed as a pasture or hay-grass, and that it possesses none of the injurious qualities of the variety *robusta*.—*Ibid.*

THE PERRIER PROJECT.—Sir Mount Stuart Grant Duff presided yesterday at a meeting of the Indian section of the Society of Arts, when Colonel Hasted, R. E., of the Local Government Board, and formerly Public Works Secretary to the Government of Madras, read an interesting paper on what is known in India as the Perrier project. By the construction of a dam 155 feet high across the valley of the Perrier a lake will be formed, from which water will be taken by means of a tunnel 6,650 feet long through the mountain top and dropped down the eastern face of the Ghauts into the Vravanasur. The latter falls into a tributary of the Vigny, and these rivers will carry the water about sixty miles to a point west of Madura, when it will be distributed by artificial channels over the country. Colonel Hasted claimed that the situation and circumstances of the locality make the operations more serious than would be the construction of a large reservoir in the Welsh mountains. The work was commenced in 1887, and it is expected that it will be completed within eight years. The total estimated cost, taking the rupee as equivalent to a florin, is 618,500. A discussion followed the reading of the paper, and the value of the scheme was fully recognised.—*O. Mail*, May 1st.

JAMAICA: THE EXHIBITION, &c.

(Extract from a letter of Mr. W. Sabonadière's dated 21st April 1891.)

The Exhibition has in itself been a great success, but the attendance only about pays the current expenses, and the guarantors will have to pay up every penny for which they are liable. I wrote a letter in the *Gleaner* suggesting the loss on the Exhibition should be made good out of the surplus revenue, brought about by the Exhibition, but the Governor will not hear of it, and wants Jamaicans to be patriotic for the good of their country; declares himself ready with his £200, and believes he has had full value for it, and so he thinks should every other guarantor. When the time comes I guess he will find he has reckoned beyond his post, and that this guarantee business will turn out a sad fiasco. The Legislature is still "en séance," and immigration has been renewed, 500 coolies arrived lately, and as many more shortly expected. The Public Works Department has received some very hard and very justifiable knocks from our member Mr. Espout, who introduced the now hated mongooses, and whose wife is a daughter of Major Armit, R. E., formerly stationed at Kandy. Our crops are very backward this year, our heaviest picking will not be on till May and June. We have had a dry spring which should be favorable for good crops in 1891-92. I see Ceylon peaberry has sold in London for 141/6. This beats Blue Mountain hollow even at Liverpool. Our sizers unfortunately do not throw out peaberry and they don't seem to care for it at Liverpool.

Dr. Calder is interested in rice growing at the western end of the island where there is plenty of marshy and swampy land; and he wants to get as much information as possible on the subject; hence partly his present order for your *Tropical Agriculturist*.

NEWS FROM "THE CITY."

(From a correspondent.)

The following news by mail of 8th May may interest you:—

"Adamson, Bell & Co., a firm largely interested in China tea, shipping &c., have come to grief. The unsecured creditors will have rather a bad time of it, the heaviest being the Yokohama Specie Bank (Japanese). Other Eastern banks supposed to be well secured.

"The Ceylon tea export frightens importers as well as buyers; for if India and China send to England more than last season the market will be glutted in August and September. Very high prices have been paid for the new Hankow teas by Russian buyers, and it is feared that the Chinese may be encouraged to prepare a large third crop, most of which would come to England.

"Ceylon Plantation Coffee steady for fair colored parcels. Ceylon Cocoa 113.-123 for brighter pale lots. "Cinchona has advanced to 1½-1½ per unit Quinine has also recovered to 10½ to 11d for German.

A CINNAMON ESTATE LIKASE CASE was tried before the District Court, Kalutara, on the 28th May in which Mr. Jardine of Goluapokuna had to give evidence. The plaintiff was Mr. S. R. Fonseka, his case being against the lessee of one of his properties who had out his cinnamon about after a very unplannerlike and injurious fashion. Mr. Jardine had no hesitation in testifying against the lessee. Judgment was reserved.

TOBACCO CULTIVATION IN SUMATRA AND IN CEYLON.

From the Singapore papers we learn that the tobacco industry in Deli is in a very critical condition. For some time past matters have been going from bad to worse, until now the planters have to face a serious problem. The causes of this state of things are three,—competition by Borneo, low prices, and exhaustion of the soil. As is well known, the tobacco plant is one that draws from the soil in a very short space of time all its nutritive constituents, and leaves it impoverished and unfitted for the cultivation of any product. Even guano, it is said, is unable to restore to the soil the phosphates needed to produce the plant at the desired level of quality; and the only thing to be done is to let the land lie fallow until nature has restored it to its pristine condition of fertility. But what are the unfortunate planters to do meanwhile? The remedy is said to be in the planting of tobacco in other parts of Sumatra, such as Indragiri and Palembang, where suitable land can be had on easy terms. It is possible therefore that there may ere long be a wholesale exodus of planters from Deli to the abovementioned districts. But then the question arises, will it pay? As we have said, prices in Europe are very low except for the finest qualities, and stocks are ample; so that, altogether, the lot of the tobacco planter is not a happy one. The recent experiments with tobacco by Europeans in Ceylon have also—with few exceptions—not been encouraging; and we think that there can be no doubt that, in this island at least, tobacco is more suited for native garden cultivation than to be grown on a large scale by Europeans. At any rate, the experiences of the Deli planters is not one to inspire confidence in the enterprise.

WANTED, A "WITHERING MACHINE"—MR. JACKSON?

A "proprietor" who has no connection with any Engineering business, writes from the Central Province:—"I have a letter from the manager of an estate who sends his leaf to a neighbouring factory to be manufactured: 'I have had to stop plucking; not from the lack of leaf but because the factory is chokeful of wet leaf which will not wither or cannot be withered fast enough in this weather.

"I wish Mr. Jackson would bring out his new withering machine which will pay him better than spending money on those land sharks of lawyers in Colombo. I hear his new drying machine, the 'Britannia' is a great success."

CULTIVATION OF CHINA GRASS.—An attempt to cultivate China grass is to be made on a large island, "La Isla Menor," on the shores of the River Guadalquivir. It is intended to plant 5,000 acres with the grass, and to erect a mill for the production of goods from the fibre. The scheme is to be carried out with English capital, and 100 acres are to be planted at first. A capital of £6,000 has been subscribed in order to make experiments, one-half of which has been furnished by the proprietor of the land, and the other half, by an English capitalist, who represents a syndicate. The scheme excites much interest in Seville, as that city would be greatly benefited by the accomplishment of the projects.—*Public Opinion*.

ELEPHANT LEATHER.

"The tanning of elephant hides," says the Boston *Journal of Commerce*, "is comparatively a new industry. The method employed is practically the same as in the tanning of cow hide, except that a stronger combination of the tannic ingredients is required, and greater length of time, about six months, is necessary to perform the work. When the hide is taken out of the vat it is $1\frac{1}{2}$ inches thick. Articles made of elephant hides are expensive luxuries. A small pocket-book of elephant's leather, without any silver or gold ornamentation, costs about \$40. A small satchel made of the same leather costs from \$800 to \$400. Clear cases, card cases and similar articles vary from \$25 to \$100. Floor rugs are also made out of the leather. In finishing the hide no attempt is made to glaze or polish it. Everything is done to preserve its natural color and appearance. It is a very enduring leather, several years' wear having but little effect on it."—*Bradstreet's* April 25th.

THE BATTALGALLA ESTATE COMPANY.

CAPITAL £15,000, IN 1,500 SHARES OF £10 EACH.

REPORT TO THE SHAREHOLDERS OF THE BATTALGALLA ESTATE COMPANY LTD.

LADIES AND GENTLEMEN,—I. In presenting this our first report to the shareholders, the Directors have much pleasure in expressing their belief that the expectations entertained at the formation of the Company are likely to be fully realized. The Company took possession of the Battalgalla estate on the 1st of January, 1890, and during June acquired the adjoining estate of Hadley (228 acres) at a cost of £4,552 10s 0d, the purchase money being provided by a further issue of shares to the extent of £1,000.

2. The produce sold in London during the working year amounted to 120,851 lb. of tea, realizing net £4,749 1s 7d, or an average of 10·70d (say 10½d) per lb. on London weights, and 11,251 lb. cinchona bark, realizing net £106. 3s. 5d. A certain quantity of green leaf from Hadley has also been sold in Ceylon and the proceeds have gone towards the upkeep of the estate.

3. Some quantity of coffee, say about 90 to 80 cwts, now afloat, from both estates will go into the new year's working accounts.

4. The factory, now completed and fitted with the latest improved machinery, is fully capable of dealing with the produce of both estates, and the Company will also manufacture a certain quantity of tea for neighbouring estates on terms leaving a fair profit; some contracts have already been entered into.

5. The total cost of the factory, which is one of the finest in Ceylon, will be about R28,000, exclusive of about £525 for machinery. Of these amounts only £1,752 8s 0d appear as yet in the accounts. The balance still due to the contractors is now being gradually liquidated. This delay in payment is a considerable saving to the Company on account of the lower exchange now ruling.

6. With this factory the heavy outlay for having the Company's tea manufactured outside, which amounted during 1890 to no less than R13,349·76, is avoided for the future.

7. A considerable increase in the outturn of tea may be expected in the current year, as both estates have now been put into excellent order by supplying vacancies where necessary, draining and manuring. The expense of this, it may be noted, has been borne by revenue, and less will be required for this purpose during the current year.

8. The Directors are pleased to express their full appreciation of the valuable services rendered them by the Manager in Ceylon, Mr. E. G. Harding, to whose zeal and ability as an experienced planter the success of the Company is mainly due.

9. After transferring to the credit of profit and loss accounts the profit shown in the estate working account of £1,205, providing for interest on debentures, and for the entire preliminary expenses connected with the formation of the Company, there remains at credit a sum

of £916. The Directors propose to pay a dividend at the rate of 5 per cent per annum, free of income tax, amounting to £45, and to carry forward £341.

E. H. Hancock, O. A. Reiss, A. Zimmern, *Directors*,
A. B. Tomkins, *Secretary*.

51, Lime Street, London, E. O., 13th April, 1891.

THE CEYLON TEA PLANTATION COMPANY.

ANNUAL GENERAL MEETING.

(Concluded from page 34.)

Mr. SHAND said he should like a little more information about the affairs of the company than that contained in the report. The report of the Ceylon Plantations Company was looked for, not only by the shareholders but by all interested in tea-planting in Ceylon, with almost the same amount of interest as the Budget was by the British taxpayer. (Laughter.) It was, therefore, of very great importance that it should contain as much information as possible. The report of two years ago contained abstracts of what each estate was doing, and when he saw that statement he felt a very keen longing to be a shareholder of the company. Now they were in ignorance of what the expenditure in Ceylon amounted to. The company had spent a great deal of money in purchasing estates recently, but he thought the main point of the board should be, not only to extend the company's property, but to improve the position of the original shareholders. He took it that the directors were very satisfied with the purchases they had made, and he thought it would be an advantage if the particulars of those purchases were conveyed to the shareholders.

Mr. SEATON thought it would give greater confidence to the shareholders to be supplied with fuller details of their estates as asked for by Mr. Shand. He certainly considered that the directors should give them a list of their estates and the cost at which tea could be made on those estates per pound down to a decimal fraction, which was done by other tea companies.

The CHAIRMAN, in reply, said that the position of the company, now and when they first started, was very different. When the company started it was perfectly true that, in order to enlighten the public and advance the credit of Ceylon they had given fuller details in their report, but a great deal had been done in four years. The Ceylon tea industry was now in a different position, and was an established undertaking. He believed a profit of something like £500,000 was made out of tea by the growers. Even assuming that the influence of the company was so great as represented by Mr. Shand, he did not think they were called upon to give all the details now that they did in the early history of the company. They, however, had nothing to conceal, and he believed an examination of their accounts would confirm even more strongly than the report showed on the face of it their sound financial position. He did not think it was desirable to weary them with a mass of details, but to give them the basis on which their profit rested. That he thought, was better than giving them elaborate details of the cultivation and cost of the estates.

Mr. D. REID (a director) pointed out that it seemed to him very unusual to give a full detailed account of their business to the shareholders at a public meeting, but if any shareholder called at the office he would be able to obtain all the information he required.

Mr. PAINE doubted whether he would be in the interest of the company to publish the details asked for. The CHAIRMAN promised to consider the question when drawing up the next report.

The motion was then put and carried unanimously. The CHAIRMAN proposed the re-election of Mr. David Reid as a director of the company, which was seconded by Mr. Rutherford and carried.

On the motion of Mr. Paine it was resolved that the remuneration of the directors for the current year should be at the rate of £600 per annum.

After the re-election of Mr. R. H. Miller, of Messrs. Harper Brothers, as Auditor of the company, an extraordinary general meeting was held for the purpose of considering and if deemed expedient, passing the following resolution:—"That the directors be authorised to purchase, or acquire from the owners thereof, the following estates in Ceylon, viz.:—"Wess Holyrood", containing 537 acres or thereabouts, "Ardalio", containing 211 acres or thereabouts, "Rathinillokilly", containing 239 acres, or thereabouts, or any of them, or any part thereof respectively, with the buildings, machinery, implements, live and dead stock, crops, produce, stores, effects, and other property belonging to said estate or any of them, or any part thereof respectively, and the business, assets, and liabilities, of the respective owners or vendors of the said estates in respect thereof, or any of them, or any part of such business, assets, and liabilities at price or prices not exceeding in the whole £27,000, payable in cash or in fully or partly paid up shares of the company, or partly in cash and partly in such shares, and upon such terms and conditions in all respects as the directors shall think fit."

The CHAIRMAN formally moved the resolution, which was seconded by Mr. PAINE, and carried.

On the motion of Mr. Seaton, a vote of thanks was then given to the CHAIRMAN and directors, which concluded the proceedings.—Cor., local "Times."

CEYLON TEA IN AMERICA.

MR. RUTHERFORD'S SCHEME.

The following is the purport of the proposal formulated by Mr. Rutherford and read by him at the meeting in reference to the representation of Ceylon at the Chicago Exhibition:—"Mr. Elwood May, President of the Ceylon Planters' American Tea Company, has represented to me that in order to give thorough confidence to his American friends, and to prove to them that his company has the full support of the tea planters of Ceylon, it is of the most vital importance to its success, that if possible, all Ceylon tea estate proprietors should be shareholders in however small a degree. I have pointed out to Mr. May that it must be hopeless at this stage of the company's career to enlist more shareholders amongst the planting community. It is, I believe, admitted on all hands that the American continent is the country above all others in which Ceylon tea ought to be pushed. Mr. May has shown me many proofs that his company is pushing our teas in the large American cities, that the teas are becoming widely known, and that the sales are increasing. An enterprise like this cannot be worked on niggard lines, and to succeed must have unlimited capital to work with. Mr. May states that the capital will be forthcoming if he is placed in a position where he can show his friends that it really is what it professes to be a Ceylon Planters' Company. He says he feels as if he were sailing under false colors in calling it a Planters' Company under the auspices of the Planters' Association when it has received such poor support from those whose interests it was created to benefit. It has suggested itself to me that the object Mr. May has in view might be attained through the means of the 'Tea Fund.' I think it is beyond question that our representatives at Exhibitions in various countries have stimulated the demand for Ceylon tea. At the 'World's Fair' at Chicago the Ceylon planters should be prepared to make such a show as to command success. My proposal is that the whole amount collected for the 'Tea Fund' for the current year should be handed over to the Ceylon Planters' American Tea Company on the following terms:—That the Ceylon Planters' American Tea Company shall represent the tea industry of Ceylon, on behalf of the Ceylon Planters' Association, on conditions to be hereafter arranged and submitted for the approval of the Ceylon Association. That the Estate proprietors whose names are on the 'Tea Fund' list and have subscribed not less than R50 during the current year to the fund shall receive one fully paid 20-dollars share in the Ceylon

Planters' American Company. Those who have subscribed less than fifty rupees on paying the difference will be also entitled to receive one fully-paid share. By this scheme it appears to me that the Ceylon planters would be employing the proper agency to represent them at the Chicago Exhibition, as the American Tea Company would have the strongest possible motive—that of self-interest—to make the representation a success. As to the issue of scrip to all subscribers to the Tea Fund alike, with the proviso as regards those who have subscribed less than R50, I do not think subscribers to the Tea Fund would expect to get an allotment in proportion to their subscription. The sole object of this part of the scheme is to ensure what Mr. May so much desires, the bringing in as shareholders, as far as it is possible, of every tea proprietor in Ceylon. With practically the whole tea proprietorship of Ceylon as shareholders in this company, there can be no doubt it will show those friends of Mr. May who are prepared to take up the balance of capital that the planters are in earnest in their endeavours to push their tea in America.

Mr. Rutherford's proposal was well received by those present at the meeting, who were of opinion that, if proper arrangements were made for ensuring an adequate representation of Ceylon industries generally, as well as Tea, as was done at South Kensington in 1886, by a well-equipped Ceylon Court under an official commission, the affair should be a success in every way.

A meeting of the Tea Committee to consider the above proposal is convened for the 11th instaut.—*Ibid.*

TEA FROM THE STRAITS SETTLEMENTS.—An invoice of forty-seven packages in seventeen breaks from Perak realised an average of 87d per lb. The tea was in very small lots, and found less favour with buyers in consequence.—*H. and C. Mail*, May 15.

A "TEA CROPS" CYCLE.—A planter writing from an old coffee district propounds the cycle theory for tea crops, thus:—

Tea, I fancy, will follow the fashion of coffee in having a cycle of three years; good, bad and indifferent. Last year most planters complained of being short of their estimate (bad); this year most estimates will be exceeded (good); so we must look for an indifferent year next year (from 1st July).

CEYLON TEA AT CHICAGO.—Mr. Elwood May has requested the attendance of all interested in the Ceylon Tea Industry at the rooms of the Association on Monday at 3 p. m. to hear his views as to the sale of Ceylon Tea in the United States and elsewhere. Mr. H. K. Rutherford has had another interview with him, and the result is that the former has designed a scheme which will accomplish all that Mr. May proposes, now that he has dropped his dream of a tea "corner", and this he will submit to the meeting on Monday. Briefly it amounts to this. Mr. May says that in order to make their Tea Company the success it will certainly be it is necessary to assure the American public that the Company really represents the entire planting interest in Ceylon, which at present it is not in a position to do. Now Mr. Rutherford says that, inasmuch as the subscribers to the Ceylon Tea Fund are about to invest a considerable sum in running Ceylon tea at the Chicago Exhibition, he will propose that every subscriber of R50 to the fund shall have a share presented to him, the amount of the money so voted for the Exhibition to be handed over to the Company for the purpose of pushing your teas within the building. That being so, the planting body and the London Tea Committee will be directly represented by the Company, which Mr. May says will ensure its success, as any amount of capital would be found under those circumstances, whilst Ceylon planters will be doing no more than they have already resolved on doing, that is, work the Exhibition for their tea, whilst they will have all the advantage of the local experience of the Company's working staff.—*London Cor.* Local "Times."

CEYLON TEA IN AMERICA:

SPEECH BY MR. ELWOOD MAY.

We have received the following from Mr. A. Philip, Secretary to the Planters' Association of Ceylon:—

4. Mining Lane, London, May 8th.

A. Philip Esq., Kandy, Ceylon.

DEAR SIR,—Mr. S. Elwood May addressed a meeting of gentlemen interested in Ceylon Tea here on Monday last, and I enclose for the information of your Association a report of his remarks on the occasion.

At the close of Mr. May's address Mr. Rutherford suggested a scheme by which the estate owners of Ceylon would become, all, to a small extent shareholders in the Ceylon Planters' Tea Company of America. He suggested that, that Company should represent the Planters' Association at Chicago and that the receipts of the Tea Fund for a year should be voted to defray expenses at the "World's Fair" on condition that the American Company should allot to each subscriber of Rs. 50 to the Tea Fund a fully paid 2 Rs. dollar share in the Company.

Our Tea Committee meets here on Monday next to discuss the resolutions of which I enclose a copy, and by next mail I will write you further on the subject.

By S. S. "Rowa" I am sending you the Tea service for Mr. Taylor and also some 30 packets of Tea about which I will also write to you fully by next mail. The Committee is rather at a loss how to act as to further prosecutions and wishes the position to be made quite clear to the Standing Committee of the Tea Fund before incurring further expense.—I am, yours faithfully, (Signed) Wm. MARTIN LEAKE.

RESOLUTIONS SUGGESTED BY MR. S. ELWOOD MAY.

No. 1.—*Resolved*:—"That owing to the adulteration of Ceylon tea after it leaves the hands of the Planters, the Ceylon Association in London, in view of the fact that such adulteration has rendered it necessary for the Association to prosecute many vendors of packet tea, deems it desirable after hearing the explanations set forth by Mr. S. Elwood May, President of the Ceylon Planters' Tea Company in America, that the Planters' Association of Ceylon do give an assurance that this Company was formed under their auspices for the sale of Ceylon tea absolutely pure and unadulterated in America, and that they have received and accepted a satisfactory written guarantee from the Company to this effect."

No. 2.—*Resolved*:—"That the Association, impressed with the great benefit the extended market in America for Ceylon teas must be to the Island of Ceylon and to all those interested in it, and considering that the efforts of the American Company should be heartily encouraged, do strongly recommend that Mr. H. K. Rutherford's proposal be approved by the Planters' Association of Ceylon."

Mr. S. Elwood May said that they would have to hear with him as he had not addressed a meeting before. His idea in coming over from America in connexion with the Ceylon Planters' Tea Company was to see gentlemen interested in the Ceylon tea industry and ask them to join him in forming a sort of trust in the American sense of the term. Such a scheme would take him hours and perhaps weeks to explain. Briefly the idea was to form such a combination as would keep out, not all competition, but competition when it was of the kind that had been experienced in England to such an enormous extent—he referred to the form of competition that consisted in advertising and selling tea under the name of Ceylon with very little Ceylon tea in it and much of everything else. While in England there were laws dealing with this matter, there was at the present time nothing in America to prevent anybody from selling any mixture with a pinch of Ceylon in it and calling it Ceylon tea. Now, it was his firm belief that fifty or sixty million pounds of Ceylon tea could be sold to the world pure. The Company had sold in America 100,000 pounds in pound packets in three months, absolutely pure as it left the planters. The identity of

Ceylon tea was unimpeachable; nothing could be got like it. Some of the leaders in London to whom he had explained his scheme said that it could not be done. They in America believed that anything could be done that was right. Some people did things there that were wrong; there was no doubt about that. He believed he had been looked upon a little with the eyes of suspicion—and he could well understand it—as having some idea of making a great combination by which the London market should be shut out. But that was absurd, for if that had been his intention he should have gone to Ceylon direct. The price obtained for tea in America was so good that profits would be from 50 to 300 per cent. Of the 100,000 pounds sold by the Company no part realized less than 50 per cent profit, and some yielded as much as 200 per cent. To show what large profits were made by combinations like the one of which he had been speaking, he might mention the Standard Oil Company of America, which in eight years had paid 100,000,000 dollars in dividends. He and other members of the Ceylon Planters' Tea Company had been spending their time in educating the consumers of America. The Company did not believe that the dealer, or the broker, or anybody else in America was of the same vital importance as the consumer. The idea was to get the consumers to demand the Company's brands, and that would force everything. The Company sold a tea called "Bud"—really the tips of the Ceylon leaf, as he understood it. They charged five shillings per pound for it retail. It cost the Company only 40 cents, it was sold to the grocer at 80 cents, and he made a profit of 45 cents out of his customers. Referring again to the combination which he (Mr. May) had hoped to form he might say at once that at the request of several gentlemen whom he had met in England he had dropped that part of his scheme, although he had heard no argument that had changed his mind at all as to the advisability of taking such a step. He had studied the question for four years and had not sprung the proposal upon them. It had received his most careful thought and consideration, and had been passed by many of the best heads in America. If such a combination should ever be floated in the future, the London contingent, even to the smallest broker, would be represented. The old Company had made a failure. Americans called a concern a failure when it showed no result. The hooks were not of such a character as to bring in new investors. Well, he was brought in and made President of the Company, and he had devoted all his time and energies to finding out what could be done with Ceylon Tea in America. He found that America did not like the teas from Japan and China. The Consul of Amoy had said to the American Secretary of State that the tea sent to the United States was the worst stuff that it was possible to get in the world. He and his friends also discovered that the Ceylon tea they had sold was used to carry off the rubbish from other countries. He was now in this position. The Company could get investors, but could they get people who had faith in the movement, and, perhaps, in himself? Everybody who came into the office said, it was a good thing, but they asked if there were really any Ceylon planters in it. They wanted to know if it was expected that the American people would put money into a concern to be worked for the sake of the Ceylon planters, who would yet take none of the risk. He did not see his way, either, to bring in only American people to make a market that anybody outside might come into and spoil. He wanted to educate the people of America to appreciate Ceylon tea, pure. But in cases such as Kenley & Tooge with their "Ceyliu's" and other brands; mixtures with very little Ceylon tea in them. This was teaching the people to detest Ceylon tea. The American never went half way in anything, and if he got the notion that the tea he took was Ceylon and was not good, he would have no more of it. He (Mr. May) wanted the planters to aid him in letting the American Tea Company show what a splendidly large market there was in America for pure Ceylon tea. In order to give some idea of the kind of assistance he wished for

he would read the resolutions he had drafted. (Attached Resolutions read.) Mr. May added that the Company had given a guarantee to the Association in Ceylon that they would not blend—that they would sell only *pure* Ceylon. (Correspondence read between the Planters' Association and the Ceylon Planters' Tea Company.) In the course of conversation Mr. May remarked that he had been paying all his own expenses in connexion with the Company. He knew that Ceylon tea could be made a tremendous success in America—not on the English plan, nor on the French plan, but on a plan that would meet the peculiar characteristics of the American people. A great deal was done in America because it was fashionable. The Company could sell a large quantity of tea at a sovereign a pound, and still more at 12s and 8s. These prices were for teas that would in England fetch only 5s, 3s 6d and 2s 6d respectively. Asked why the original Company had not been successful, he said that they took a shop at R4,500, having really no plan or system at all. He did not wish to make any reflections upon them, but to his mind they went to work in the wrong way. They tried to get the tea into the hands of the merchants, and this was a mistake. They should have gone to the consumers direct.

WATERSPOUTS OFF THE COAST OF CEYLON.

Anent your recent remarks about waterspouts in connection with the remarkable escape of the S. S. "America," a well-informed friend reminds me that in November 1863 or 1864, the schooner "Adee Letchimy" was caught in a waterspout between Paumben and Mannar with a party of immigrants on board. Her sister ships on the same voyage were the "Sarah Armitage" and the "Geraldina Alexandrina Roche," both well-known crafts in Colombia, the latter owned by Roche Victoria—but they happily escaped the fate of the "Adee Letchimy." It appears that the tidal, though warned by some of the passengers, was apparently ignorant of the danger impending and neglected to take the necessary precautions for the safety of the vessel in his charge. The result was most calamitous. The schooner according to the testimony of the survivors was actually lifted out of the water, coming down again with such fearful violence, that she became a total wreck. Upwards of 20 of the crew and immigrants perished. Portions of the wreck were picked up near Kalpitiya.—*Cor.*

BARK AND DRUG REPORT.

(From the *Chemist and Druggist*.)

LONDON, May 7th.

CINCHONA.—The supply of bark offered at Tuesday's auctions was a moderate one, consisting of:—

	Packages	Packages	
Ceylon cinchona ...	478 of which	452 were sold	
East Indian cinchona	1,188 do	1,188 do	
Java cinchona	203 do	203 do	
South American cinchona	196 do	29 do	
Total ...	2,065 do	1,872 do	

It will be seen from these figures that nearly 91 per cent of the bark offered was disposed of, a proportion much in excess of the usual percentage. The assortment of bark was not a very superior one, the bulk of the parcels consisting of *Succinbras*, and there were scarcely any good ledger barks. Competition throughout the sales was well maintained, and prices advanced from 10 to 15 per cent on the previous auction rates, the unit ranging from 1½ to 1¼ per lb., the latter price being paid for some of the richer lots of bark.

The following are the approximate quantities purchased by the principal buyers:—

	Lbs.
Agents for the Mannheim and Amsterdam works	94,739
Brunswick works	92,202
Frankfort o/M. and Stuttgart works	70,312
Auerbach works	52,167
Messrs. Howard & Sons	40,570
Agents for the American and Italian works	39,525
French works	33,065
Sundry druggists	16,847
Total quantity sold	439,427
Bought in or withdrawn	34,050
Total quantity offered	473,477

It should be well understood that the mere weight of bark purchased affords no guide whatever to the quinine yield represented by it, firms who buy a small quantity of bark by weight frequently take the richest lots and vice versa.

QUININE.—The market is again decidedly stronger, and shows an advance of about 3d per oz. since our last report. On Tuesday there were buyers of German in bulk at 10½d per oz. This morning a sale of 5,000 oz. B & S quinine (second-hand), May delivery, was reported at 10½d per oz.; and later on in the day one of 5,000 oz. at 11d per oz.

SPICES.—Cinnamon: A parcel of 51 bales Ceylon, imported in 1889, was offered without reserve this week, and sold at 7½d to 8d for first, and 7½d for second quality.

CLEARING THE UNIVERSE: RARE PLANTS.

In one issue of a newspaper the other day we remarked three paragraphs. The first announced that "the most prized of our orchids are reported to be rapidly disappearing from their native places"; the second, that "the only hope of preserving the fur-seal from extermination is said to be to stay their slaughter for six or seven years"; the third, that "nearly all the principal animals indigenous to the United States are either substantially extinct, or in immediate danger of becoming so." These are the words of Professor Lingley, head of the National Zoological Park at Washington. Three such statements, published side by side, as it were, upon authority, give food for thought. Incontrovertible in themselves, their significance might be strengthened by endless illustrations. As regards orchids, Messrs. Steves announced last month, at a public sale, that the Government of Ceylon has forbidden the gathering of a certain species—*Dendrobium McCarthya*—for an indefinite time, to preserve it from extinction. Another, the loveliest of all, as some think, *Laelia elegans*, would have vanished from this lower sphere had not some few specimens found a lodgment on cliffs absolutely inaccessible, where the Indians eye them with vain longing. Of the grand variety of *Laelia purpurata*, which enthusiasts call the "true," not a plant remains in its native seat. The commonest of fine orchids half a century ago were *Cattleya's Mossia* and *Trianae*, as we perceive by the great quantity still surviving in our greenhouses. At this time, they are classed among the rarest in Caracacas. The best variety *Odontoglossum crispum* was found along the Pacho River in such profusion that early collectors pronounced the supply inexhaustible; the *Journal des Orchidées* states that "only a few plants are now left." Not to prolong the list, it may be declared that every species, in every part of the world, for which there is a great demand, begins to fail. They cannot be replaced unless Government interfere—and vigorously too, for the profits of smuggling, while they last, would be enormous. Orchids will become a royal fashion, indeed, when they cease to be weeds in their native home. Among the hundreds of skilful horticulturists who have tried again and again in the last half century, but one has been successful in raising any member of the great *Odontoglossum* family from seed; this happy individual is M. Leroy, gardener to M. Edmund de Rothschild, and his plants have not yet flowered. Other genera less intractable demand five to sixteen years of most careful cultivation before they produce a bloom. Which means, in brief, that the grower would ask their weight in gold for his nurselings.

But orchids are commonly regarded, even now, as luxuries in which the general public has no interest. That is a grievous mistake, but we may

let it pass. The public feels an interest, however, in fish, and that product also is threatened. Year by year the trawlers seek new ground, and still the price rises. They have cleared our coasts so far that fishermen themselves, the least nervous of mortals, and not the most intelligent, demand protection, to save their industry from collapse. It is not worth while to speak of oysters. All the world knows that our famous "natives" have vanished, and miscellaneous foreign species occupy their beds. For the daily supply of lobsters we depend on Scandinavia eked out by America; how long these will last is a matter for calculation. Such inland waters as are open to the public have been cleared of big fish long ago, and the continual replenishments scarcely keep pace with the multiplication of anglers. So desperate we grow that perilous designs of acclimatization are welcomed. The black bass of America, the silurus of Southern Europe, will be turned down shortly in our narrow streams and tiny lakes, where assuredly, if they themselves give sport they will kill off all the natives. A pastime which some of us remember with especial delight "tickling," or "grappling," is forbidden by law with reason enough under the circumstances. Like its rival in the memory of veterans, birds'-nesting, it had to be suppressed for the "preservation of the species." Country lads find more blameless sports now, perhaps. So we must hope. But the pursuit of Lepidoptera is not for all, and there are still myriads of boys who can rarely enjoy a game at cricket in the holidays. They suffer by the clearing out of wild creatures which have amused every generation of English youth. And the farmers suffer also. Eagles, kites, buzzards, and bustards have gone. Owls and hawks are following. While we write, Parliament is debating whether or no it is worth while to arrest the extermination of hares.

The romance of the universe will be eclipsed when wild beasts disappear; and the time draws on. Professor Langley, whom we have quoted, makes a strong appeal for the preservation of such as still survive in North America. May it be successful; but we fear. Close seasons may be appointed, and hunting parties may be forbidden. But the area of cultivation will spread, and settlers will still be armed with weapons more and more and more deadly. The same process is going on everywhere. Startling it is to learn, for those who knew South Africa but twenty years ago, how far a man must travel beyond the Orange River to find even springbok—an antelope which he remembers covering the veldt in thousand as he drove northwards from the Karoo. The zebra alone appears to be actually lost; but all other species which were prized in Cape Colony are represented by a few specimens here and there. Government is roused, and some landowners preserve strictly. But as men multiply they will have land, and they cannot be prevented from shooting game to eat. Already there is an agitation to do away with the Reserve at Uitenage, where the last survivors of the elephant is South Africa find a narrow home. It may succeed presently; but before those pachyderm vanish they may also have outlived their kindred beyond the frontier. As peace is established in Central Africa population will grow, and in defence of their crops the natives must wage war upon the most destructive of all animals—putting ivory and "sport" aside. The hippopotamus, the rhinoceros, which do not seek the shelter of dense forests, will even predecease the elephant. Buffalo will last longer, no doubt; but the antelopes, all of which haunt pasture-land, and are all food, will not hold their own so long. And the great felines must go with them.

It is the same in Asia. Elephants have been preserved for a good many years now in the Indian and Cingalese jungles, where they still exist. But these jungles narrow continually. The Census returns published a few days ago show an increase of twenty-two million souls, the vast majority of whom belong to the agricultural class. They euroach on the forests and the waste lands year by year. It is cultivation, not slaughter, which thins wild beasts. There is a pathetic passage in Sir Samuel Barker's recent work. He tells of a visit paid—in 1878, if we remember rightly—to the hunting grounds of his youth in Ceylon. Not a head of game could he find in districts which teemed with deer and buffalo thirty years before. Thirty years hence, so far as we can see, big game will be extinct in Ceylon.

It is all for the best, no doubt. Wild beasts have become a sort of anachronism all over a world full of beasts that are not ostensibly wild. But something of interest will vanish from human life when they are lost. Increase and multiply and replenish the earth is a divine command, but in fulfilling our destiny faster and faster, we seem to be exterminating the beautiful. Nor is it by any means assured that Nature will not exact compensation. But a month ago one would have declared with absolute confidence that the extinction of alligators would be a blessing unmixed. Not a redeeming virtue of any kind do those brutes possess, we thought, and all who know them had been rejoicing to hear that the demand for alligator leather threatened their existence. But now we learn that the waning of their numbers is spreading panic in Florida. The musk rat increases so fast that riverside plantations have been ruined. And the danger grows more serious month by month. An act has been hurried through the Legislature, imposing a fine of one hundred dollars on the man who wilfully kills an alligator, under any circumstances, during the next three years. No stronger instance could be found of the peril that attends human interference with the system of Nature.—*Saturday Review.*

ELEPHANT-CATCHING OPERATIONS IN MADRAS.

The success that has attended its elephant-catching operations has induced the Madras Forest Department to extend them. The operations were inaugurated in North Malabar in 1884, since when the capture of elephants has been confined to North and South Malabar and South Coimbatore. Thirty-one elephants have been captured, of which 17 are now working; one escaped; one was sold, and the remainder died. Of the last the death of four are attributed to the gross ill-treatment and neglect of the Forest subordinates, who have been brought to task and dismissed the service, 16 of the elephants were caught in North Malabar, 12 in South Malabar, and 3 in South Coimbatore. More elephants would have been taken in South Coimbatore, where operations only began last year, but for the exceptional dryness of the season, owing to the failure of the South-West and North-East monsoons. The operations have been carried out under the supervision of the Forest Officers, Messrs. Morgan, Hadfield and Porter, and great credit is due to them. The pit system is the one employed for the capture of elephants, for it is considered by these officers superior to the khedda system, there being little or no risk of injury if sufficient precautions are taken and reliable men are told off for the work. The estimated cost of the capture of an elephant is

about R250, viz., actual cost of capturing R50; mahout for 5 months, while under training, R60; cavalry R35; fodder and rations, R75; super-visions and sundries R30. The value of the elephants at present possessed by the Department is estimated at R10,500. After capture and removal from the pit unnecessary severity is avoided, and the animals are trained, being kindly treated and receiving as rewards jaggery, sugar-cane or other delicacies. In about five months the training is complete and the elephants put to work with others in dragging timber etc. As there is a certain amount of personal risk incurred in the work of capture, rewards not exceeding R100 are proposed to be granted to the subordinates employed for each elephant captured and properly trained and which is in good condition at the end of six months.

In this connection it will not be uninteresting to summarise what a correspondent, who signs himself "Kurumber," writes to the *Asian*. He prefaces his remarks by referring to the report that Admiral Fremantle, while at Trincomalee, went on a shooting expedition to Vellar plain, 15 miles from Mutur and there bagged two elephants, "a dame and her baby." Can, he asks, this horrible tale be true? If it be so, all he can say is that "some people have curious ideas of what constitutes sport. The wanton butchery of harmless animals that are perfectly useless to the man who shoots them, and very often to every one else, is simple cruelty, and all true sportsmen, who are humane and do not needlessly inflict pain on dumb beasts, can only shudder at such doings." "Kurumber" should not have commented on the Admiral's sport without having made himself acquainted with all the facts of the case. Admiral Fremantle, we may mention, had shot the female when its baby, which had at first bolted, turned round and charged the Admiral and his party, and in self-defence the former shot the innocent suckling. That is all. "Kurumber" then refers to the reprehensible conduct of the Ceylon Government in allowing every big-wig and globe trotter who visits Ceylon to murder the elephants without restriction. This is not, we believe, a fact, for the Government is just as anxious to preserve those mammoths of the forest as "Kurumber." The Madras Government then comes in for a share of this angry correspondent's attack. We will quote what he says, merely remarking that if the Mysore Government wishes to exterminate the elephants in the wholesale manner attributed to it by "Kurumber" it has every right to do so, as far as we can see:—

"Here, in Southern India, the Madras Government looks placidly on whilst a fondatory State (Mysore) carries on the extermination in a more wholesale manner. For years the wild elephants have been most carefully protected by Government, apparently in order that the Mysore Government should reap the entire profit by catching and selling the animals which the Madras Government has bred for them, and this with the assistance of a trained officer lent by the Supreme Government! It is just the same thing as if you possessed a large and well stocked game preserve, and then assisted your neighbour, with the loan of your game-keeper to shoot down in his small holding the game that you bred and preserved for his benefit! The folly of the Madras Government in looking on whilst lakhs of rupees worth of its elephants are being captured wholesale by the Mysore people with the help of the Government of India, is beyond ordinary comprehension. When the Mysore Government has caught all the elephants belonging to Madras perhaps the Supreme Government will wake up to the fact that they have no more

elephants to preserve! Then I presume they will purchase elephants and turn them loose to restock the forest! Our present Governor, Lord Wenlock, is however a very different man to his predecessors, and he has only to discover the terrible damage that is being done to counteract it as soon as possible."—*M. Mail*.

"HISTORY OF COFFEE;" MR. PETER BROHIER'S TRANSLATION.

Kandy, 18th May 1891.

To the Editor of the "*Tropical Agriculturist*."

DEAR SIR.—I was glad to see in the *Tropical Agriculturist* (see pages 874, Vol. X. and 5 and 12) the translation of the "History of Coffee" from the Dutch of Valentyn. This translation was made, about 35 years ago, by Mr. Peter Brohier (the father of the present assistant Auditor-General), who was then a retired public servant and had been chief clerk of the revenue branch of the Audit Office. Mr. Brohier, (who was the son of the late Captain John Brohier Provincial Judge of Puttalam)* was a good Dutch scholar and an accomplished musician. After his retirement from the Government service, he spent much of his time in translating Dutch works. The translation in question was originally a contribution to one of your contemporaries. The planters of the day and others were much pleased with the work, and a leading European gentleman wrote to the translator, that apart from the merits of the translation, he was quite delighted with the humorous summaries which headed each chapter; and that above all, he was charmed with the little Turkish poem which was rendered so felicitously into English. This contribution afterwards appeared in a Pamphlet form, and at the suggestion of Mr. Hew Stewart, the facetious editor of the "*Times*" a copy of it was forwarded to Mr. Alexander Brown, the Secretary of the Planters' Association, whose attention was called to the fact that a preparation very much like "Pale Ale" might be prepared from the coffeehusk or shell. And the worthy Scotch Secretary, whilst thanking the learned translator for the copy sent to the Association, informed him, that he did not believe the planters were just then prepared to try the experiment suggested, as the coffee berry "pure and simple" was paying them hand over fist.

—Yours faithfully,

SIGMA.

INDIAN ART APPLIED TO THE ILLUSTRATION OF INDIAN EPICS.

As attention has recently been drawn to the industries of Jeypore in connection with the magnificent gift of £20,000 to the Imperial Institute by His Highness the Maharaja, it may not be inappropriate to notice the really artistic work done by native artificers in that city. The Ramayana shield alone would be sufficient to prove the marvellous skill of the workman who holds the premier place in Jeypore. The general idea was taken from the Milton and Bunyan shields of Morel-Ladouit, and the story of the Ramayana is told in a series of plaques, nearly all of which are faithful reproductions in relief, in silver-plated brass, of paintings by the most celebrated artists who flourished in Akbar's time. Ganga Baksh Khafi, is the workman who carried out the idea which Dr. Hendley conceived, and visitors to Jeypore, when they see this shield, can realise that the art of working in metals still survives in India. The figures of men and animals are perfectly reproduced from the old paintings, and nothing is wanting in those details which the native artist only too often neglects. Dr. Hendley has now arranged for the production of two more large shields. One of these will be a companion to the Ramayana shield, the story of the Mahabharata being

* Captain Brohier, the Provincial Judge of Puttalam, wrote the "Historical Account of Ceylon" which appeared in the *Ceylon Literary Register* of last year.

taken as the second great epic poem of the Hindus. Here again the paintings of Akbar's time will be copied. The other shield will be known as the Ashwamedha, and will contain seven plaques. In olden days, says Dr. Hendley, a curious custom obtained of the expiatory sacrifice of a horse. The animal, selected by a ruling Chief, was allowed to wander at large for a year. Those who disputed the supremacy of its owner, took possession of it and fought to retain it against all comers. "If the horse came safely through his trials he was sacrificed with elaborate ceremonies, and the victorious monarch was then acknowledged as paramount sovereign." The sacrifice which Yu ishtira performed, has been chosen as a fitting subject for illustration on the shield. The drawings have been taken from Akbar's own copy of the Razmnamah or Persian version of the Mahabharata. The adventures depicted are extremely curious. The horse goes through several transformations, and visits very strange countries. In one of these the trees produced as fruit men, women and animals, who lived but a day. The inhabitants were monsters with blanket ears, in which they wrapped themselves at night. In Maninra the people were all virtuous; there were no wars, the men were all brave and the women submissive to their husbands. The exact position of this wonderful land is unfortunately not made known. The wonderful horse worked miracles when he appeared, and eventually he was sacrificed with due pomp, ascending to the heaven of Brahma and becoming a constellation. The subject should test to the full the skill of Ganga Baksh Khatri, to whose hands the shield will be entrusted. Many months of patient labour will be required before the Malabarata and Ashwamedha shields can be placed alongside the Ramayana; but Jeypore will in the end possess three specimens of metal work in relief unrivalled throughout India. Dr. Hendley may well be congratulated on his successful efforts to foster indigenous talent, which in these days, if left to itself, would probably never have risen to any very high level.—*Pioneer*.

MARBLEYIA (Theberton) 28th May.—Fearful rainfall so far since burst of monsoon which was on the night of 20th, as no wind on the 19th till a. m. 20th.

Rainfall.		Rainfall	
19th ...	3.19 in.	26th ...	2.58 in.
20th ...	5.00 "	27th ...	2.74 "
21st ...	5.42 "		
22nd ...	5.11 "	9 days	40.19 "
23rd ...	4.84 "		
24th ...	4.77 "	Average for 9 days	4.465 "
25th ...	5.54 "		

Still raining heavily, not quite so bad as before. We have had violent squalls of wind with this rain since 1 a. m. of 20th. Total so far for May, viz., to 27th 57.42 in.—Not bad!

THE REPORT OF THE DIRECTORS OF THE DARJEELING COMPANY made up to Dec. 31st, 1890, shows that the quantity of tea manufactured in the season of 1890 amounted to 606,950 lb., being a considerable increase of 57,172 lb. over the crop of 1889, but the tea brokers have informed the directors that the usual high standard of quality was not maintained, and, consequently, the average price realised for the crop is only 1s 0.66d per lb., against 1s 2.10d per lb. for the crop of 1889, showing a decrease of 1.44d per lb., which, on the whole quantity disposed of, represents a deficiency of 3,573l. The proportion of teas of fine quality was unusually small during the past season, and high prices were realised for them. Out of the profit on the season's operations the following claims have to be provided for:—To commissions to staff, 843l; to income-tax, 222l, leaving a net profit of 6,266l, which is equivalent to 4l 12s 6d per cent. on the paid-up capital of the company; and it is therefore proposed to transfer from the undivided profits the sum of 1,859l in order to provide a sufficient amount to enable the members to declare a dividend at the rate of 6 per cent. for the past year. So far the prospects for the season 1891 show an improvement over last up to the middle of April, but the quantity of tea manufactured up to that early period of the season has always fluctuated considerably.—*O. Mail*.

RESERVE FORESTS.—The grand reserves of forest still held by the Government between the upper reaches of the Bentota river and Sabaragamuwa or extending into that province, are not generally realised. In one block, about 8 to 10 miles from the river, there are 8,000 acres very fine reserve forest, with big timber trees. A great part of the Sinha Raja forest has suffered from chenaing in the days of old; but there are still 10,000 acres perhaps of fine heavy jungle, while the chenaed portions are many of them of a considerable age now.

BAMBOO CHARCOAL.—It is generally thought that bamboo being so light and small makes a bad fuel wood, and no one would think it of any value as fuel for forges; yet it is considered the best material for making charcoal for blacksmith work, and is in large demand all over Mysore. It is said to give off more heat than the best coke and to require less blast. A maund of bamboo charcoal fetches twice as much in the village-markets as the best charcoal. The method of charring bamboo is different to that used for harder woods—the stacks or kilns being carefully covered with green leaves and then plastered with wet clay. While the burning is going on care is taken to exclude air as much as possible without extinguishing the fire.—*Bangalore Spectator*.

WEST INDIAN CONCENTRATED LIME-JUICE.—Among the industries which might probably be established, or, rather, developed, within the limits of the empire, with a prospect of yielding a probable return, the preparation of concentrated lime juice for the manufacture of citric acid deserves to be mentioned. England is still the country where citric acid making is carried on most largely, and at present almost the whole of our supply of the raw material for its manufacture is obtained from Sicily. The concentrated juice market in Messina is usually dominated by a gang of speculators, and it is to be feared that the actual producers of the article receive but scanty return for their labour. Indeed, it is asserted that when the price of juice falls below a figure not much lower than that at which it stands at present, the juice-makers cannot get a living at their occupation. But these conditions, even if correctly stated, by no means preclude the possibility of successful cultivation elsewhere. The lime is as plentiful in the West India island as the lemon is in Sicily, and in the conditions of land tenure, taxation, and labour, our colonies may possibly compare favourably with the Italian island. As a matter of fact, concentrated juice from the West Indian limes—the province of Dominica—has for a good many years been placed on our markets in small lots and at irregular periods, but it is questionable whether the possibility of providing a regular supply at a remunerative price has ever been figured out with any approach to precision, though it might very possibly be quite as deserving of consideration as many other suggested means of industrial advancement to the West Indies. It is doubtful whether the total amount of concentrated West Indian lime-juice received here amounts to as much as 100 pipes a year—not much more than the average Italian supply of one week. Moreover, the West Indian pomaceons only contain about 50 gallons whereas the Messina pipes are of 108 gallons capacity. The West Indian juice is very much stronger than the Italian; in fact, its high test is not altogether an advantage, as the evaporation is carried so far that the juice not infrequently becomes burnt. The usual strength of Italian juice is 64 oz. of citric acid per gallon, and the contracts under which it is sold provide for an allowance if the strength falls below 60 or exceeds 66 oz. The West Indian juice usually contains 90 and occasionally over 100 oz. of acid per gallon. Hitherto the West Indian juice has been sold at a relative price generally running about 10 per cent below that paid for the Italian article; but it seems not at all improbable that with a more careful method of manufacture, it might not realise as much as or more than the latter.—*Chemist and Druggist*, May 16th.

Correspondence.

To the Editor.

FOR CEYLON TEA PLANTERS.

London, E.C., May 1st.

DEAR SIR.—The enclosed figures have only just been issued—too late for our circular. We therefore send them to you that you may publish them if you think fit.

MARKET drooped on Thursday. What a pity it is that planters cannot be induced to make larger breaks? This is a most important matter, and affects the market far more than can be understood. Many a buyer will purchase 500 chests of tea if in seven or eight lots and think nothing of it. Put the same quantity into twenty lots and he fancies he has bought an awful lot of tea; he has a long list instead of a short one and a crowd of samples instead of only a few—in addition to which the work entailed in selling the twenty lots is three or four times as great as in selling only six or seven. Cannot you use your powerful influence to help the Ceylon tea trade in this important matter?

QUALITY.—We are very sorry to note, in valuing teas for next Thursday's sale, a further falling-off.—We are, dear sir, yours faithfully,

GOW, WILSON & STANTON.

KOLA AND ITS PREPARATIONS.

London F. C. May 1st.

SIR.—If the reports of the experiments made at Aldershot by Horace Manders, F. R. C. S., have not already been published I think many of your readers would find them interesting.

This gentleman initiated the experiments for the Indian Government and after carefully examining all the different forms of kola in my warehouse selected a certain quantity of each form for trial, amongst others a certain quantity of the pure kola powder. As we cannot at present give you a full report of the experiments, suffice it to say that the kola powder surpassed all other forms in sustaining properties.

On Wednesday morning the experiment commenced and continued till the following Saturday night.

Each morning a teaspoonful of kola powder was taken in hot water and 1½ ounces dry rusk during the day. Mr. Manders found that he suffered no inconvenience whatever from hunger or thirst and he strongly recommends the use of kola on all expeditions, etc.

Owing to this series of experiments we have been enabled to decide that a teaspoonful of dry kola equal to ½ oz. is quite sufficient to take during

12 or even 24 hours. At the advice of Mr. Manders we prepared a kola wine and bitters; these he pronounced entirely satisfactory. We were fortunate enough to obtain the hearty co-operation of one of the largest wine merchants in London for the wine, and one of the largest distillers for the bitters; and further it was decided that it was best to supply the bitters so that they are ready for consumption without any mixing whatever. Having in this country every appliance for obtaining the fluid and solid extracts of kola we were enabled to make the very best preparation of biscuits in different form, but none of these gave very good results.

What is considered of very great importance is that if anyone is on an expedition they could put a pinch of this kola powder into the rice from a tin box, and as it has no appreciable flavor it would not be noticed, but would nevertheless impart its enormous sustaining power even perhaps to a greater extent than if partaken of as a watery infusion. I think this will show you that I have been on the right track in recommending the planting and introduction of kola wherever it is possible in our colonies.

Already we have had reports from Burma from some of the merchants and others who have been using it and who are more than satisfied with the results. Especially has this been the case in the hot weather as they have been enabled with kola to support the great heat in a way which has perfectly astonished them. No foreign Government or representative has ever had in Europe the success which has attended the experiments made by Mr. Manders. As we know that there have been experiments carried on in India we hope that you will be enabled to obtain possession of the particulars so as to put them side by side with the abbreviated report sent you.—Yours truly,

THOS. CHRISTY, F.L.S.

[We have to call attention to Mr. Christy's advertisement of kola preparations in another column.—Ed. T. A.]

“SOAPSTONE” OR RATHER “RENSE-LAERITE” IN CEYLON.

May 9th.

DEAR SIR.—I send you a small piece of “soapstone” found by a native correspondent in the lowcountry. It is the first time I have found any. Kindly let me have your opinion of its value (if any) and relative merits.—Yours truly,

EXPLORER.

Dear Sir,—Herewith I send you a piece of metal which is named by the natives of this place “nil garunda” and used for medicinal purposes as belly-ache, snake bites, &c.; but I considered it to be a metal which belongs to the marble kind found in Ceylon. If you think that you could possibly make any benefit out of it I shall thank you to let me know. It is found only in one place of this district in one of the Crown lands.—I am, sir, your obedient servant,
E. H.

[We referred the lump of yellow-looking stone to Mr. Geo. Armitage, who has just completed his examination and pronounces it to be a variety of talc called “Ronschlaerite,” much harder than the soapstone of commerce. The latter is used for a variety of purposes including gas burners, the lining of stoves, &c. The specimen sent to us has a specific gravity of 2.63 and Mr. Armitage does not think it will be of commercial value.—Ed. T. A.]

MALE AND FEMALE COCONUT TREES.

SIR,—I have never seen any mention of the fact that some coconut trees appear to be capable only of producing male flowers and are consequently barren. These trees bear the ordinary small male flowers in quantities but the bracts are void of female florets. Another variety of coconut tree produces both male and what appear to be female flower, but these latter are defective and incapable of fertilization, and though they produce fruit, yet these last when opened are found to consist of only the outer husk or coir.

The above are facts which have come under my own observation, and I would be glad if I could get any explanation of them, or be informed by any of your numerous readers if there are any means whereby such a disastrous state of things could be obviated or avoided, and whether trees which have already been established could be grafted or otherwise made to produce fruit.—I am, &c.,

P. FOSTER HUGGINS,

Golden Vale, S. Vincent, West Indies.

[On this very interesting subject, Dr. Trimen, as well as such coconut planters as Messrs. Jardine, Lamont, Bevan and others may have something interesting to say.—Ed. T. A.]

CEYLON TEA IN SWITZERLAND AND AUSTRIA.

Winterthur, May 13th.

DEAR SIR,—I am much obliged to you for the insertion of my name in the list of the supporters of the Ceylon Tea Industry. The sale of Ceylon tea in this country is increasing slowly, but steadily. There are now also other sellers of this tea, who probably buy it in London; but who very likely would never have touched it, if I had not made the beginning. In this way the Ceylon tea industry is benefitted also indirectly. I beg leave to ask you to add to the list of supporters of the Ceylon Tea Industry the name of my friend, Mr. W. Weiner, 7 Bezirk, 5, Montergasse, Vienna, the capital of the Austro-Hungarian Monarchy, whose efforts made on behalf of Ceylon tea were acknowledged by the meeting of the Tea Fund Committee on April 10th last, to the minutes of which (under the heading Ceylon Tea in Switzerland) please refer.—I, am dear sir, yours truly,

CHARLES OSSWALD.

MALE AND FEMALE COCONUT TREES.

Veyangoda, May 15th.

DEAR SIR,—I am afraid I have nothing interesting to say in reply to Mr. Foster Huggins's enquiries. I have never come across a coconut tree producing male flowers exclusively. In very rare instances a tree is met with unable to mature its fruit. I believe the fact of the flowers producing fruit, even although they may never reach maturity, proves that the flowers cannot be male. Such trees I have always regarded as the result of defective seed. I am confirmed in this belief by Simmonds, who in his "Tropical Agriculturist" says, "those nuts which may be taken from trees of immature age will, if any plants are successfully reared from them, grow very rapidly, but the fruit will drop before the kernel acquires consistency."

I do not think it quite accurate to regard as a "variety" those trees that produce nuts consisting only of the outer husk. I have heard these nuts described by a govt. who was translating into English a notarial agreement from the vernacular, as still-born nuts! These trees too, I consider as a result of defective seed. If the tree that produces these undesirable nuts—if what is without nuts can be rightly called *coconuts*—have a strong, vigorous trunk and a good head of leaf, and in other words are worth preserving; a heavy dose of manure consisting mainly of bone dust will cure them of their bad habit. I

have a very vigorous looking tree which produced nothing but husks. The appearance of the fruit betokened their emptiness. The same bunch had on it nuts of various sizes and apparently of various ages, and would, if seen by him, have confirmed the contention of a member of the Metropolitan Bar that nuts of various ages are invariably to be found on the same stalk! I came to the conclusion that the tree was wanting in stamina and gave it a very heavy dose of cattle manure, with bones and ashes: that was about a couple of years ago. I now find that the nuts of the tree is producing seem to be filling out, and I have hopes that they will prove to be good ones. If it will interest you, I shall send you a stalk with nuts of seemingly various ages.

There are some trees that bear very heavily and the nuts are large and well filled out apparently, but which are minus the kernel, or in some instances have it of a dirty brown colour and covering only a portion of the shell. Water is absent from such nuts. Whether it was present during the earlier stages of growth, I had never an opportunity of finding out; but I suppose it was present in small quantity. These trees, too, can, I believe, be brought round by manuring with phosphatic manure. I have made a trial.

The cure I would recommend for a barren tree is to improve it off the face of the earth. Surely Mr. Huggins cannot be serious when he enquires "whether trees (coconut) that have already been established could be grafted?" Science will have to advance a good deal I think before such an operation becomes possible; the idea is quite Yankee.

During the seasons of the year that coconut trees bear heavy crops, empty or "still-born" nuts increase in number proportionately. This proves I think that they are the result of impaired vigor in the tree, for at such seasons the resources of the tree are taxed to the utmost to mature the large number of nuts they are carrying. Liberal cultivation lessens the number of empty nuts materially.

Perhaps the Superintendent of the School of Agriculture and his Assistants, some of whom claim to have been bred under the shade of the coconut tree, can contribute something interesting on the subject.

When a coconut tree commences bearing, the first few flower spathe thrown out contain abortive blossoms, these are called in Sinhalese *Boru mal* or false flowers. The length of time a tree continues to throw out these *Boru mal* is dependent on its vigor and affords a sure index of its bearing capabilities through life. Weakly trees continue to bear abortive blossoms for years running, and when they do bear it is only a few nuts per annum. It is best both for the appearance and value of a young property to courageously root these lumberers out and to replace them with 3 or 4 year plants; a supply of these is a necessity, they are better able to maintain the struggle for existence in a property where the roots of the trees cover the ground than a nursery plant. To attempt to get the hard trees to bear is an expensive and disheartening job; at the best they only repay what is spent on them.

B.

KUSH-KUSH YAMS:

DEAR SIR,—I am in a position to say kush-kush is an imported plant and I believe comes from the West Indies. Messrs. Whyte & Co. of Kandy deserve the thanks of the public for its introduction into this island. A friend of mine bought about 20 tubers originally from the above firm and first cultivated it on a leased land at Veyangoda, gradually extending its cultivation till he sold the yams delivered in Colombo to a good many of his acquaintances and public at R10 per cwt., at which rate it paid him. I was the means of getting this introduced into the Bentota district through the late Mr. Lewis Mendis, who got his tubers from Veyangoda. The proprietor of "Comilla" also obtained tubers from the same source and cultivated it a few years back extensively, and I am under the impression had Messrs. Auwardt & Co. as his agents selling it in Colombo.

Your correspondent "W. B. L." secured his tubers from "Comilla" a few years back, since which he has kept up its cultivation which as he says is rather expensive wanting a good prepared soil with plenty of manure. I also got another gentleman, an official, to cultivate it on his property at Hewagama Korale, but I am afraid this gentleman has given it up and has confined his attention only to coconuts and pepper, the latter of which he firmly believes in as paying handsomely. I remember sending a few specimens of the yam to your office and the then editor was pleased to say after trial that it was equal to or even superior to the best Jaffna. I say so as well unhesitatingly, and would strongly advise you to procure some specimens from your worthy correspondent "W. B. L." when you will endorse my opinion.

HORTICULTURIST.

OVER-PRODUCTION OF TEA.

Sir,—Referring to what H. E. the Governor said at the Dimbula breakfast, respecting over production being the chief danger tea planters need fear, would it not be well, before the danger comes too near, for all tea planters to combine and push their teas in countries where they are now little known, notably on the continent of Europe and in Australia?

It would greatly strengthen the hands of the "Ceylon Tea Fund" if all planters would join and give 37 cents per 1,000 lb. of green leaf, which I am willing to do for as long as may be necessary if my brother planters will do the same.

Please give my name and address to any enquiring persons.—Yours truly,

PROPRIETOR.

OUR COCONUT SOILS.

DEAR SIR,—Not being a learned scientist myself, I am obliged to take such scraps of science as I need at second hand, but I am somewhat nice about the authorities I consult—applying only to such as have made a name and position in their own branch of investigation. When B. assumed that silica was deficient in certain coconut fields I applied to Professor Geikie, who gave me the following information:—More than one half of the earth's crust consists of silicate; it is an essential element in all igneous rocks, from which all sedimentary rocks and soils are ultimately derived; it is therefore not only abundant but everywhere present. In regard to the agricultural value of silica, the following sentence from a recently published article by Professor Johnstone disposes of that question:—

"Now silica and silicates are decidedly injurious to all vegetables doubtless, but in particular to agricultural plants, I say injurious; the time has gone past for considering silica an essential, a useful or even an innocuous accessory."

OLD PLANTER.

[We suppose it is our correspondent who quotes Professor Johnstone's dictum which certainly surprises us. One-half the crust of the earth composed of a substance which is noxious and only noxious to agricultural plants! "Cinnamon sand" is about 98 per cent silica, and yet the finest cinnamon in the world grows in such sand.—Ed. T. A.]

CKACKLING OF JUNGLE HENS.

Adampan, May 19th.

Sir,—Re cackling of jungle hens, I am afraid I am rather late, but yet, should you deem the following of any interest, they are at your disposal.

I have had the opportunity of observing or rather I made it a point of studying the manners and ways of wild animals in general, and the question now at issue has been one of them. I could say from my own knowledge that the jungle hens do not cackle after lying. They have four peculiar notes:—one when they fly alarmed, one when they feed with the cock in reply to call, one when calling the chickens, one warning the chicks: the latter three similar to the domestic hen but in a softer key. The jungle hens lay more than four eggs; I have taken as many as nine and I have seen a brood of eight chicks. I have never heard a jungle hen cackle and the cock replying in a similar key, as among the domestic fowls. The cock when singing out his "George Joyce" flaps his wings nearly like to his domestic cousin.—Yours truly,

K. DE HOEDT.

THE CHEMISTRY OF SOILS.

Voyangoda, May 19th.

DEAR SIR,—I cannot say with "Old Planter" that I am a "learned scientist," for I say to pretensions to being a scientist at all, whether learned or unlearned. Like him the information I got on scientific subjects is from books; but I do not enjoy the same privileges as he in the choice of my authorities. My authorities are the ordinary text books that can be increased at the discretion of the Observer Office. A very respectable book by Alfred Russel Wallace gives precisely the same information as Professor Geikie does. Silica is the predominate constituent of most rocks, rocks and minerals; it is the most abundant solid material of the earth. My old friend has put it down to the unnecessary trouble of consulting such authorities "as have made a name and position in their own branch of investigation," to refute a statement of allegation I did not make. It is the old game of being a man of back and one's own creation. The statement which A. B. has made occurs in the first of my articles on this, where I say that I have done my best but the extent they cackled trees grow on the bamboo support their "old hunches" may be owing to a "deficiency" of silica. A little further on would have satisfied "Old Planter" that I could not possibly be in a deficiency of silica in the soil, but I had the impression of the fact, for I stated over and over again that one of the properties of salts is to be soluble in water, and silica in the soil, and to be soluble in the soil. I hold to the belief that this silica is dissolved and diffused vegetable matter. Owing to the straw of wheat containing considerably over 50 per cent of silica, it was for long considered that soil mineral was absolutely necessary to the soil for growth and that it gave stiffness to the straw. Recent experiments at growing wheat on soil devoid of silica have disproved this belief. Dr. Emil Wolf has conducted some experiments in the same direction, and his verdict was that the silica was not indispensable for plant growth, yet the absorption of silica greatly assisted the assimilation of other plant food, and that plants to which silica was supplied showed better development than those without it. Now I contend that I have high authority of the belief I hold. All engaged in agricultural pursuits have had experience of the difference between the possibility of making a produce grow and growing it into a healthy and well developed specimen. The difference is that between the growth of a produce, a loss and a profit. Besides this to my mind the experiments only went to prove that silica was not essential to the growth of wheat; they went no further.

And now I come to the second part of the letter of "Old Planter" where he quotes with approval the dictum of Professor Johnstone. I may remark en passant that I take it for granted that "Alexander Johnstone" is a Professor solely on "Old Planter's" authority, for though it may display my ignorance of the names of the shining lights of the scientific world, yet

I honestly say that of my own personal knowledge I do not know that he is a Professor. Not only must he be a Professor, but one who "has made a name and position in his own branch of investigation," or according to his own showing "Old Planter" would not have thought fit to parade his opinion. In the March number of the *Tropical Agriculturist* there appeared an article on "The Action of Lime on Clay Soils" signed "Alexander Johnstone," Edinburgh University, and extracted from *Nature*. In it I read with a great degree of astonishment the statement quoted by "Old Planter," and I mentally classed it with the startling and revolutionary theory of Mr. J. A. Reeves, that as it was against the laws of gravitation for water to ascend and it could rise only some thirty feet by capillary attraction, therefore it was impossible for sap to rise. He attributed to the roots the functions usually ascribed to leaves and *vice versa*. I regarded it as a bold bid for fame, more especially as he states in the opening sentences of his article that to the best of his belief "the scientific reason for the beneficial action arising from the application of quinine has not been at any time satisfactorily explained"! This in the face of all the "scientific reasons" given by learned chemists down to very recent times. To supply this omission, he offers "an explanation, or rather theory, which, to my, doubtless, somewhat partial mind, seems to go a considerable way towards the elucidation of the problem." It will be observed that what he advances is only a "theory," which seems to go a considerable way to his partial mind towards &c. And yet this is what "Old Planter" triumphantly puts forward. Professor Johnstone goes very much further than those whose experiments only went to prove that silica was not essential to plant growth. He avers that it is "decidedly injurious," particularly to agricultural plants. And yet it abounds in the earth, from which I suppose people yet believe, in spite of Mr. Reeves, that plants mainly draw their sustenance, to the extent of more than a half of its composition. I suppose it will be conceded without demur that the earth was mainly created for the growth and support of vegetation. Can we reconcile with our belief of an all-wise Creator the composition of the earth with a substance which is its predominating constituent and which is yet "decidedly injurious" to all vegetation? If it were an injurious plant food, plants would avoid it, but what do we actually find? "The wheat plant is always found to contain a large proportion of silica, although it may have been raised on a lime soil." Is it not against the laws of nature to find a plant deliberately choosing what is "decidedly injurious" to it?

What to my lay mind is a weak argument that Professor Johnstone adduces in support of his theory, is the fact that silica is to be found generally in the external tissues of plants: this he regards as the attempts of vegetation "to get rid of it as speedily as possible—that is to get it out of the way of its general circulation." To my mind these external incrustations of silica both on grain and in the outside tissues of plants and trees prove that they are intended by nature to serve a very useful purpose. They act as a shield to them against injury and insect attacks. In the case of paddy we know that till the outside covering of the grain is hardened they are liable to be punctured or sucked dry by bugs. In the case of coconut trees, the hard outer-covering of the stem is that which protects them from the attacks of red beetle. So with other trees.

Believing as I do, what Dr. Wolff's experiments prove that silica helps in the assimilation of other plant food, and that its presence in a soil helps to the better development of vegetation, I must be pardoned for holding tenaciously to the belief that salt by helping towards the solution of plant food in the soil, including silica, will help coconut trees in time to overcome the bad habit of not being able to support unsided their fruit bunches.

It may be superfluous to add that I have discussed this question entirely from the point of view of a layman.

[Iron has long been undervalued as a mineral possessed of fertilizing properties. It is so under-

valued no longer, at any rate by tea planters in Ceylon. Soils largely ferruginous suit this plant admirably, while the virtues of iron slag as a manure are now loudly proclaimed. Silica, too may have virtues not dreamed of in our philosophy. In any case we cannot bring ourselves to believe that the most prevalent of all minerals is injurious to agricultural plants.—Ed. T. A.]

TEA STATISTICS AND PROSPECTS.

Colombo, May 20th.

Sir,—In 1868 the export of tea from China by sea was	164,000,000 lb.
do by land	14,000,000 "
The export from Japan, India &c, say	12,000,000 "
	<hr/> 190,000,000 lb.

Gow, Wilson & Stanton's "Tea Consumption" make the World's annual average consumption of tea for the 5 years 1885 to 1889	393,000,000 "
	<hr/> Increase 203,000,000 lb.

Taking the average of 1885 to 1889 to be equal to the consumption of 1887, the increase in 19 years, as we may suppose the export for 1888 to equal the consumption of that year, is at the rate of 10 684,210 lb.

The export from Ceylon for the present year to 18th May (5½ months) is 9,694,025 lb. in excess of the export to same date last year, so we seem to be going ahead too fast. The falling-off in exports from China may be balanced by increase from India and Java.—Yours truly, NEMO.

PLANTING STATISTICS.

C. P., May 21st.

Sir,—Up to what date were the figures for cultivation on estates given in your last Directory? Am I not right in saying they are now about a year old and that the area under tea must be a good deal larger now?—Yours truly,

TEA PLANTER.

[Our Planting Statistics in last "Handbook and Directory" were made up as to 30th June 1890. No doubt there has been a considerable increase in planted area since and, notwithstanding the risk of over-production, we suppose a good many clearings are to be planted during the present monsoon season. We are arranging for a fresh compilation in a smaller volume, of which more anon.—Ed. T. A.]

AN ENEMY OF THE COCONUT.

May 26th.

Sir,—Under separate cover I try to send you two beetles, the larva of which are called by the Sinhalese *kanda panuwa* and which are responsible for an immense amount of damage in young coconut plantations. Will you kindly give their scientific name, for which I have searched through your publication "All About Coconuts," but without success. COCONUT PLANTER.

[We cannot find the scientific name of this very common weevil: perhaps some reader can supply it.—Ed. T. A.]

LABOUR SUPPLY FUND.

Gannadua, May 28th.

DEAR SIR,—The present time is not precisely similar to the past, inasmuch as in the past (the old coffee days) the labour supply was required

at a certain period of the year, for crop chiefly, and when pruning was finished, only a few coolies were required to keep the estates in order during the rest of the year.

Now it is necessary to have a good force of labour all the year, as the system of tea cultivation, now generally adopted, is to divide the work as much as possible over the whole year. Instead of pruning the whole of the tea on an estate in one or two months, a pruning force is kept employed quarterly, thus the larger portion of the estate is always in bearing, and the coolies fully employed at all seasons.

With a Labour Fund Committee and its Secretary in Kandy, an estate manager in want of labour would forward his cheque to the Secretary to cover the advances required to procure and forward to him a certain number of coolies by a given date, say within a month. The Secretary acknowledges the cheque and wires to the Agent of the Committee in India by code the requirement, and follows up the message by letter. The agent draws on the Secretary for the amount required to procure the coolies and through his sub-agencies arrange to despatch the coolies on a certain date, which he communicates by wire to the Secretary, who advises the applicant for the labor, to send a trustworthy person to meet the coolies. Now, in 1891, we have far more facilities for successfully carrying on such an agency than had our predecessors. The difficulties of the past need not deter the planters of the present from making an Agency a great success. I crave permission to further remark, that experience has told most of us, that advances actually sent to the coast are frequently misapplied, the labor we expected and should have got could not be brought for want of the further sum the kanganyes wrote for and master did not send.

Coolies may be plentiful and willing to come, but for some reason or other they don't come, and year after year the cry is for labor, and whole fields of fine tea have frequently been allowed to run to wood for want of the necessary labor to pluck them. It is our duty to seriously consider, whether an active Agency or an Intelligence Committee is most required to meet the urgency of the increasing labor requirements.

I believe that under a Labor Supply Fund Committee it will be possible to keep an adequate force for all requirements at less expense to proprietors, and without friction which so frequently arises amongst managers about their labor supply.—Yours faithfully,
JAMES WESTLAND.

[Mr. Westland will be disappointed with our remarks of yesterday; but they contain our honest opinion. Mr. Westland seems to think that coolies would flock to a Coast Agency and its sub-branches in such numbers that there would never be any difficulty in meeting any planter's order. But suppose there were six (indeed, according to the picture of planters' needs, there might be sixty) telegrams in, ordering 300 coolies and only 100 available, or willing to move, how is the agent to act? Mr. Westland is nearer the mark in our opinion when he speaks of an "Intelligence Sub-Committee" to open up correspondence with Indian officials, or to send one of their number over to interview Collectors and Sub-Collectors of the coolie districts and to see how the labour needs of Ceylon can best be made known and supplied.—But if it be true that from want of labour, many fields of tea in Ceylon are not now plucked properly or fully, where is overproduction and export of tea to end? In place of 60 million lb. this year, perhaps Mr. Westland would say we might ship 65 or even 70 million lb. with more labour?—Ed. T. A.]

THE SILICA DISCUSSION.

SIR,—When I penned a note (which by the way, has not yet appeared in print) for an agricultural publication a day or two ago, on the reply which Professor Geikie sent to a scientific enquirer after truth in Ceylon, I was not aware, as is evidenced by the letter of a correspondent to last Saturday's (May 23rd) issue of your paper, that the Professor Johnstone referred to by Professor Geikie was Alexander Johnstone, late of the Edinburgh University. I presume that the Professor Geikie to whom reference was made on the Silica question is James Geikie, Professor of Geology and Mineralogy at the Edinburgh University, and not Archibald Geikie, the predecessor of his brother, and for that reason still sometimes spoken of as Professor, though he vacated the University chair for a high appointment in connection with Her Majesty's Geological Survey. If this be so, then both Professor Geikie and Professor Johnstone are both "old friends" of mine. I sat at the feet of the former only some three years ago, and in the course of many a pleasant geological excursion found in him a kind teacher as well as a most entertaining companion. At this time Alexander Johnstone was class assistant to Professor Geikie, a "night coach" in botany, and a fellow-student of mine in agriculture. I knew him well both in and out of the University; and as I had the highest regard for him then, I have the kindest recollections of him now. I am under an impression, which I sincerely hope is incorrect, that it was in the columns of your own paper—or one of your supplements—that I read of his death a short while ago. Alexander Johnstone was well up in his geology and a splendid coach in botany; but while I would accept any opinion of his on these subjects, I am hardly prepared to stand by his original ideas on agriculture. Johnstone's intention was to go up for the agricultural degree at the University. Whether he did so, and whether he has started as a teacher or professor of agriculture and the allied sciences in Edinburgh or elsewhere; or whether he has got a chair of botany or geology in some University or College, I never heard. My observations on the statement attributed to him have, as I have before mentioned, been noted elsewhere, and I will not therefore repeat myself in your columns.

It seems quite natural that Professor Geikie, who does not venture on an opinion as to the agricultural value of silica, should think of quoting his quondam class assistant's opinion before that of any other.

Without intending the slightest disrespect for my "old friends" (including "Old Planter"), I cannot help thinking that neither the choice of a professor of geology as a referee on the question at issue, nor that of the opinion of his late class-assistant—in preference to those of the shining lights in the agricultural world—by the Professor himself, has been a happy one.

It is very important that those who take sides in a scientific discussion, though they be only "laymen," should confine themselves strictly to scientific reasoning. Now when a correspondent, writing on the subject of the value of silica in agriculture, attempts to adduce arguments as to the importance of this common constituent of soils by making such statements as the following, he (however conscientious he may be) becomes both unscientific and illogical. Your correspondent "B." in Saturday's (May 23rd) issue says:—"I suppose it will be conceded without demur that the earth was mainly created for the growth and support of vegetation. Can we reconcile with our belief of an all-wise Creator the composition of the earth

with a substance which is its predominating constituent and which is yet 'decidedly injurious' to all vegetation?" I am afraid there will be a good many ready to demur that the earth was *mainly created* for the growth and support of vegetation. This is indeed as revolutionary a theory as that of Mr. Reeves! The appeal in the second sentence is modelled after the hackneyed atheistic argument, against the existence of a God, who, if He be the possessor of every attribute of goodness, cannot, it is said, consistently allow evil (and other things "decidedly injurious") to exist in the world. The use of the argument (absurd in itself) to prove the value of silica is as novel as it is ridiculous!

We are asked, "Is it not against the laws of nature to find a plant *deliberately* choosing what is 'decidedly injurious' to it?" Very possibly against the "laws of nature," still those that can *deliberate* a good deal more than plants do choose what is "decidedly injurious" to them. The fact is that plants may and often do take in substances present in the soil, but utterly useless in the plant economy, but the demand for these useless substances is limited as the result of the action of the law of diffusion of liquids—the so-called "selective power" of plants. The excretion of silica (or other substance) on the outer tissues of the plants is generally considered to be a means of "getting rid," as Professor Johnstone puts it, of it from the growing parts of the plant, where, though it may have at one time performed useful functions, it is no longer required, since it does not enter into the constitution of plant tissue. I admit that Professor Johnstone's statement of this fact is rather crudely put.

I may say in passing that the value of "iron" as a commercial ingredient of agricultural soils depends altogether on the particular compound of iron that is present,* while the virtues of iron slag are mainly if not solely referable to the compounds of phosphorus present in it.—I am, &c.,
D.

SALT FOR COCONUTS.

DEAR SIR,—In his enthusiastic advocacy of salt "B." has credited it with so many virtues, that if we accept his authority (and he names no other) mankind have been, through all the ages, neglecting the most valuable and important of all agricultural agents; that which dissolves minerals, and sets free plant food which dissolves minerals, and sets free plant food which previously shut up in insoluble compounds; that mechanically ameliorates the soil to the extent of rendering tillage superfluous; that absorbs water and holds it available for the use of plants when all around is dry; and that destroys coarse and useless vegetation while highly beneficial to delicate and useful plants.

It has been proved beyond question, that, with whatever substance salt may be mixed, it can be combined without loss, and without chemical change on the other ingredients of the blend: it may therefore be fairly inferred, that salt has no chemical effect on soils whatever. Rain water effects a temporary mechanical change in soil, and there is no reason to believe, that salt water will have a different or more permanent effect. Salt absorbs moisture from either earth or air, but it again surrenders its moisture to dry air or hot sun in common with the other ingredients of the soil and to the depth to which sun and air penetrate. For complete liquefaction, salt absorbs three times its own weight of water, when it follows the law, by which liquids sink by their own gravity through a porous medium. If an inch deep of salt be laid on a given surface, and let the soil under it be kept saturated with water for a month, the probability is, that not a trace of salt will remain within some feet of the sur-

face. It has been known from time immemorial, that salt is destructive to most kinds of terrestrial vegetation, but it has probably never before been credited with the quality of discrimination between the noxious and the useful.

That an excess of salt beyond its organic requirements is essential to the vigor and fruitfulness of the coconut has been so often asserted, and "B." has laboured so hard to prove it, that it is generally accepted as an established fact, but that is still open to question. The coconut trees on sea sand do little honour to their unfailing supply of salt, by the crops they yield; indeed, in this respect, they do not excel those that grow on hard gravel, and steep inclines far inland. The strength and fruitfulness of the trees growing in the Cinuamou Garden compounds may be readily accounted for, on other grounds than their exposure to salt bearing breezes. Besides, these are not the champion trees of the Island, which must be sought on alluvial flats on the banks of occasionally overflowing rivers, where some of the trees yield up to 400 nuts per annum, and there are other inland spots, where the trees will hold their own, in comparison with the Cinnamon Gardens.

It is true that much of the inland undulating uplands are not all that could be desired for coconut cultivation, but there are ways of improving them without having recourse to salt; salt cannot give moisture to the soil in a three months' drought; salt cannot pulverize a compact soil; and salt is no substitute for nitrates, phosphates and organic matter.—
Yours truly,
COCONUT PLANTER.

FLOUR FROM JAK SEEDS?

Colombo, May 30th.

SIR,—Has it struck anyone to utilize the seed of the jak fruit for the preparation of flour? The only question to decide is whether it would be a wholesome diet. There is no reason why it should not form a nutritious food: it will certainly be a cheap one, considering the large quantity of seed that is allowed to run to waste. The seeds are of course eaten roasted to some extent by the natives, and even ground to a flour for immediate use in the preparation of a sort of cake, after mixing with jaggery. If it prove to be a wholesome food and capable of being made into a flour that will keep, why shouldn't a new industry be started? The seeds might at least be exported.

I should like to know whether the idea has struck anyone before, and whether anyone has tried the experiment of flour-making?—I am, yours, &c.,
A.

[The first question to settle is,—"Are the seeds ever separated in any appreciable quantity from the other portions of the fruits?" What we see in the markets are sections of the complete fruits, with the farinaceous seeds embedded in the mucilaginous and saccharine substance in which they are formed, and we are not aware that in cooking the fruits in curries, or otherwise, the seeds are ever rejected? We should, indeed, be greatly surprised to hear that they are. But if our observation has been at fault and a supply of seeds for grinding into flour is really available, the experiment suggested ought certainly to be tried.—Ed. T. A.]

HOW TO RECRUIT COOLIES.

Kalutara, May 30th.

DEAR SIR,—Why not go in for the Assam system? A kangani is sent to his country with only enough money to take him there. On his getting coolies together, he is empowered to apply to an agent (a worthy native merchant) and they give him *not money* but rail or boat tickets to their destination for the coolies produced.

Therefore there is no opportunity for the kangani to use the money for any other purpose than bringing coolies.—Yours truly,
A. A.

* This, of course, is for iron in a certain condition is undoubtedly a cause of sterility in the Ceylon patanas.—Ed. T. A.

SIROCCOS AS WITHERING MACHINES IMPORTANT.

June 1st.

DEAR SIR,—If "Proprietor (who has no connexion with any engineering business)" will read the following directions and adhere to them he need never have more than two days' leaf in store in any weather:—

A Sirocco is almost a perfect withering machine. Pass any leaf that has no water actually on it through the trays in the usual manner at a temperature of 170° to 180°—not more—loading the trays as full as they will go in, and as rapidly as a man can fill them. Throw the contents of each tray as it comes out into an ordinary carrying basket, pressing the leaf down well with the hand. After the basket is full, which will take about 7 minutes, let it stand about 10 minutes to 15 minutes according to the condition of the leaf. Then take the leaf to the roller, beginning of course with the first basket—and roll without any pressure for half-an-hour. At the end of that time take the leaf out of the roller and return it to the baskets, pressing it down as before with the hand. Let it stand half-an-hour, (whilst a second roll of leaf similarly prepared is being rolled after which place it again in the roller and give it another 40 minutes, using pressure towards the end. Then lift and fire immediately, the fine leaf of course first. The "roll" will be found quite sufficiently fermented and as soft as silk, and will give a bright infusion and a slightly pale but pungent and flavoury liquor.

The sirocco I use for withering is one of the old 8. trays. In two rows in siroccos with four rows of trays. Only the two lower rows should be used and the leaf passed through and back again so as not to be too long exposed to the heat. I put 315 lb. of leaf, weighed before heating, into a 32" "Rapid" and 105 lb into a "Kimmond."

I may add that I have been withering from 4,000 to 5,000 lb. of leaf a day for the last ten days in the above manner, and the annexed copy of the London brokers' report on a shipment of Tea similarly treated last year will show that the quality of the tea so made is satisfactory.—Yours faithfully,

M. H. T.

Sold 23rd September 1890:—

Good infused leaf ra: strong liquor with fair flavour		

THE "BRITANNIA" DRIER.

Laookellie, June 3rd.

DEAR SIR,—It will doubtless be of interest to many of your readers who may be unable to make a personal inspection of this machine which has been at work here since 21st ultimo, if I supply a few details as to its capabilities. With this object in view I do not think I can do better than quote the results of a trial I made of the machine yesterday, when, at a temperature of 205 to 210 degrees, and passing the leaf through twice, the drier gave 302 lb. dry tea in the hour. The day was a fairly fine one, and such satisfactory returns could not be obtained in very wet weather, but there is no doubt that the drying capacity of the "Britannia" at low temperature, is far in advance of any machine we have yet had to deal with. The quantity of leaf dried by the "Britannia" is due mainly to the fact that the fan is a very powerful one, drawing a large quantity of air from an improved form of stove through the leaf, and that the trays are carried on one endless chain, as against the several separate endless chains in the "Victoria" thus presenting a greatly increased surface

of leaf to the action of the air. In the "Victoria," half the chains are always carrying empty trays; in the "Britannia" the trays containing the leaf go right through the machine without tipping until they come to the discharge hopper. As regards fuel the "Britannia" is more economical than the "Victoria" and is more easily worked by the coolies, while less liable to get out of order.—Your faithfully,

A. F. CORRIE.

DIGGING AND MANURING COCONUTS.

June 6th.

DEAR SIR,—The communication on the wonderful effect on coconut plants of digging the soil is very interesting. May I ask your correspondent to give us some information as to the situation of the land that was dug, the composition of the soil, whether the land was dug in connection with garden cultivation or independent of it, and whether a satisfactory results follow digging the soil higher up a slope as at its bottom where all the wash and ashes have been deposited by rains?

A strange fatality seems to follow my agricultural operations. My ill-success with paddy I recorded lately. In 1889-90 I forked the soil round the plants of 120 acres of young plantations, with 12 pruning forks, and gave each plant a bushel of ashes besides, but the results were nothing like what your correspondent records.—Truly yours,

B.

JAK SEED FLOUR.

SIR,—Whilst I was amusing myself in reading your valuable journal of the 3rd instant, my attention was very much drawn towards an article heading "Flour from Jak Seed." Having read throughout, I am glad to take this opportunity of giving the little experience I have had of the above question, for the information of your earnest and prospective correspondent. It I remember rightly my first trial of making jak seed flour was about five years ago, since then I took no interest whatever. The method is simple enough, similar to that of arrowroot flour making. The only additional work is to put the seed (not dried) after peeling into well boiled water, and leave it for a short time, and proceed according to the manner in which arrowroot is prepared, which I needn't repeat to your worthy correspondent. When the seed is being pounded, it gives a jarring smell enough to make one feel quite disgusted to get on with the work. I managed to make about a half-a pound of flour, out of which some biscuits were prepared, with an admixture of sugar, eggs, and milk and a little table-salt to avoid any indigestion taking place, the biscuits were palatable and nice, they were very soft, and broken easily, perhaps owing to some defects in the preparation. With regards its nutritious qualities I am not in a position to state for, but so far I had nothing to complain of after my eating it. Anyhow it will not be advisable for any one, who has any sort of windy complaints, to eat this stuff, which is so wellknown to be windy.—I am, yours,

JAKSEED.

MATTERS AGRICULTURAL.

Veyangoda, June 6th.

DEAR SIR,—Little surprise will be felt when I say that I was hors de combat ever since I saw your impression of the 29th nit. in which two adverse letters and an over-run footnote were levelled at me. I shall, with your permission, notice both the letters in one communication, as they are both the outcome of my letter on Salt. But for a blunder of "Old Planter" or your own proof-reader in omitting two inverted commas, the reading public would have been deprived of a very interesting bit of autobiography from the pen of "D." I should have thought that so subtle an intellect as "D.'s" would have detected the omission, and that he would have seen that it was "Old Planter" and not Professor Geikie who was quoting Professor Johnstone. I made this very evident in my communication and indicated where Pro-

feason Johnstone's paper was to be found. "D." demurs to what I anticipated few will demur, that the earth was mainly created for the support of vegetation. He does not tell us what his belief is. I thought it a superfluity to "add, for the use of man and beast," as that is within our daily experience; will that also be demurred to? People are so hypercritical! My idea was not original but borrowed from Holy Writ. In the account of the creation we read that immediately after the earth was created it was ordered that it be clothed with vegetation (Gen. I chap. 11 verse.) and in the 29th and 30th verses that after the creation of man and beast, that God gave them the produce of the earth for their sustenance. But "D." may be one of those learned scientists who cannot reconcile the account of the creation with the "Ologies" in which they are so deeply versed. If "D." had shown less alacrity to jump at unwarrantable conclusions and had been less lavish in the use of epithets, it would not have detracted from his reputation nor have drawn on his own head the epithets levelled at mine. It is both "absurd" and "ridiculous," but not "novel" for "D." to say that to prove the value of silica, I said I could not reconcile with my belief in an all-wise Creator the composition of the earth with a mineral "decidedly injurious" to vegetation. I said so to refute the theory of his own Professor. I think that even "D." and "Old Planter" will admit that Mr. John Hughes, the chemist, though not a shining light perhaps, is not unknown to the scientific world. He is likely to be abreast of scientific experiments and would not have been ignorant of those conducted to test whether silica were indispensable for the growth of grass; yet this is what he wrote in November 1887, on rice soils:—"The most essential thing in the soil itself is that it should be in a state of minute subdivision so as to supply an abundant source of soluble silica which is so necessary in the formation and successful growth of the straw, and without which it would be quite useless to expect to obtain a good crop. *** The best crops of wheat are produced on soils which contain plenty of available silica." The foregoing to show that I have authority for my belief that silica is useful and not "decidedly injurious" to vegetation.

"Coconut Planter's" letter is noteworthy for containing misrepresentations from beginning to end, and for an amusing display of ignorance of the subject of his criticism. He is too honorable a man for me to believe that his misrepresentations are wilful. The alternative is that they are due to a lamentable carelessness to inform himself correctly of the views of him whom he criticizes.

Not being a chemist and not being able to conduct experiments personally, in enumerating the virtues of salt I gave not my own opinion but those of persons competent to express an opinion. If "Coconut Planter" had but taken the trouble to wade through his volumes of the *Tropical Agriculturist* and consult any other book on agriculture in his possession, he would not have said that I sing the virtues of salt on my sole authority. If he carefully reads his copy of the *Agriculturist*, he would have found in the February No. that mankind have not "through all the ages been neglecting the most valuable and important of all agricultural agents."

In enumerating the virtues of salt,—the first para of his letter, he professes to quote me, but in reality misquotes me. Salt does not render tillage superfluous, it does not destroy coarse vegetation while at the same time being beneficial to delicate and useful plants. If applied in large quantities it destroys vegetation whether coarse or delicate. Coarse vegetation generally indicates a sour soil; salt is said to sweeten it and help towards the growth of good, sweet herbage.

To say that because salt can be purified though mixed with any substance, therefore it can exert no chemical influence on the soil, is to go counter to the opinion of those who are higher authorities on questions of agricultural Chemistry than "Coconut Planter." There is nothing singular in the fact that the moisture salt absorbs is surrendered to hot sun or dry air. No one to my knowledge credited salt with the quality of discrimination between noxious and useful vegeta-

tion. Coconut trees on the sea-shore were not instance as being very fruitful owing to receiving an unending supply of salt. The fruitfulness of the coconut trees in the cinnamon gardens was not attributed solely to salt breezes. They were not instance as champion trees. I too am acquainted with spots inland where for fruitfulness coconut trees will compare favorably with those in the Cinnamon Gardens; but I will hardly call the spot "Coconut Planter" resides on "inland." It was not asserted that the only way to improve coconut properties inland was by the application of salt, nor that it can supply moisture to them during a 'three months' drought, nor finally that it is a substitute for nitrate, phosphates and organic matter. My friend—I call him also friend in spite of "D."—could not have been in his usual mood when he penned the letter, which does so little credit to his character for preciseness. Can it be that he was temporarily under the influence of the "divine afflatus" and became consequently highly imaginative? B.

DRIERS AS WITHERERS.

Central Province, June 8th.

DEAR SIR,—As regards the use of a sirocco as a witherer, I see not the slightest objection to using any of the drying or firing machines as witherers, if it can be satisfactorily proved that the made tea loses nothing in value. I long ago suggested in the *Observer* the use of the desiccator or any other drying machine as witherers. At that time, I had not an opportunity of carrying out my own suggestion. Since then, and more than two years ago, I proved to my own satisfaction that the leaf passed quickly through the desiccator came out to all appearance well withered, but I was unwilling to risk any quantity as I am not much of an expert in tea tasting and I was afraid I might spoil a break. Were I pressed for space I would have no hesitation now in passing half withered leaf through the desiccator.—Yours truly, P. P.

A TEA ROLLER CASE.—Yesterday (1st) Messrs. Julins and Greasy on behalf of Mr. Wm. Jackson of Aberdeen, who is at present in Ceylon, tendered a libel in the District Court of Colombo against Mr. Alfred Brown and the Colombo Commercial Company, praying for an injunction to restrain the defendants from importing manufacturing or selling Tea Rollers which the plaintiff claims infringe his patent.—Local "Independent."

GOLDEN TIPS.—We stated recently that the prices obtained for special parcels of Ceylon tea in London had led to a sort of "golden tips" competition upon country, and we are assured that some parcels of tea are going home now that will make the Gartmore prices sink into insignificance. The new Ceylon product threatens to be turned out in such quantities that every grocer in the United Kingdom will be able to have a sample of Ceylon golden tips in his window, purchased for a fabulous price, for advertising purposes. Our Indian friends meanwhile are getting rather restive at this method of booming Ceylon tea. We quoted recently the ill-conditioned snarl of a correspondent to the *Madras Times*, and now we see that the *Calcutta Englishman* pooh-poohs the whole thing in the following disparaging terms:—"The nominal or friendly sale of a single pound of tea at £17 or £25, or even £200, is not a matter of any practical importance. We doubt very much whether it will do any good even as an advertisement. But Indian growers may content themselves with the reflection that they also will share whatever advantage may come of these so-called sales, for Ceylon is thus advertising her own and Indian tea at the same time. India has decidedly the best of it, being under no necessity of sacrificing a crop for the sake of a fancy quotation." This is certainly consoling for Indian planters.—Local "Times."

HINTS FOR A YOUNG NEWLY ARRIVED PLANTING ASSISTANT.

(By an old planter.)

IN COLOMBO.

My dear Blank,—Welcome to Ceylon. May your career here be most successful and all you hope for realized!

As much depends on the start you make in life, we may adjourn to the verandah and have a chat in a long arm chair.

What will you have to drink? You will find Colombo a very thirsty place.

I'll have a lemonade, thank you?

What, nothing stronger?

No thanks, I have thoroughly enjoyed the voyage and have tasted nothing stronger and mean to try and see how I can get on without stimulants.

Boy, bring two lemonades, don't spoil them by putting ice in the tumblers.—Have you been calling on anyone yet? No, but I have several letters of introduction, one to Mr. John Ferguson: he is the Editor of the *Observer*.

I am glad to hear you have a letter to him, he is just the person to give you hints as to how to get upcountry and all about everything that concerns Ceylon. You can call on him after you finish your drink. His office is only a short distance from the G. O. H.

TRAVELLING.

I hear you are bound for the hill country. Lucky fellow! but take care that the cooly sent to meet you to show you the way and carry your box containing a change of clothing keeps within sight; not that he will steal your box, but by your keeping together until your destination is reached, you have a change of clothing at hand which you may stand greatly in need of, as the weather is, at certain seasons, very treacherous. It may look clear and charming for a 10 or 15 miles' ride or walk when you leave the station; but before you have gone far it may pour as you have never seen it do in the old country. Even if it does not rain a change of clothing after your bath and you feel like a new man.

ON THE PLANTATION.

You will find everything very strange at first: the estate won't be like what you have pictured to yourself, unless you have seen a photograph of it; for all estates are not alike and even a photo does not give one an idea of the grandeur of the rocks and mountains, and the charming effect of the pretty little bungalows and the large factories on the tea estates. Everything will be new, the very air you breathe is different, new faces, language, work, whole surroundings all different from what you expected. If you mean to work, and get on here, you will have to get up early, say about 5-30, have tea or coffee, and make as good a meal as you can, as you have the heaviest part of the day's work to do before you get breakfast. The first duty after early tea is to take "muster," which may be either near or a little way off from the bungalow; but is generally taken in the most convenient situation for the coolies being sent to work.

The usual way of taking what is called muster, is to have all the coolies standing in a sort of semi-circle, double file, according to their gangs. The assistant with pocket checkroll or muster book in hand proceeds to the first gang on his left hand, and glancing along the line of coolies of that gang puts down the number in the gang to that kangani in his muster roll. On to the next lot, and enters them, and soon, till the total number of the gangs have been entered. This done the coolies are again arranged in double file, the able-bodied men taking one place, the best plucking women in another, the best half-grown boys by themselves, children and old women with infants fill up the balance. From

these you select the material to carry on the various field works of the day. A little experience will teach you whom to select for the particular works. When muster is finished, and all gone off to work give the coolies five (5) minutes start of you before you follow.

The first morning after your arrival be ready to accompany your P. D. (as the manager is called) should he be able to escort you to the different works going on, and listen carefully to what he tells you. If you cannot trust your memory, make notes after breakfast in your own room of the conversation so far as you can remember. You will find them useful to you in after life.

When left to yourself amongst the coolies, go quietly from one to the other, watching each one how the work is done. In a very short time you will be able to distinguish the good working coolies and learn by watching them, how the work should be done. Certain works such as plucking and pruning you will, with a little practice and under the guidance of your P. D., soon acquire a practical knowledge of, and be able to teach the careless and ignorant amongst them. To do so, you will feel your own ignorance of the language and be anxious to speak it forthwith. It is wonderful how one can get along with a little Tamil, but to be able to get on well with coolies you must get over the shameful feeling of making mistakes in using Tamil when looking after work. Watch when the kangani or overseer gives an order to a cooly, and note down the words in a small note-book and ask your P. D. or the conductor (if there is one on the estate who knows English) the equivalent in English. Every day note down a few Tamil words and their meaning alongside. Commit to memory the Tamil numbers and the days of the week, and invest in a small book called "Inge Va" to be had at the *Observer* Office. A very useful little work for assisting beginners. If you find a cooly very obstinate or stupid at doing as you want him, don't strike him, but show him as you would a child how to do what you want. Remember that you really don't know his language and you may fail in teaching, being unable to express yourself properly. If he is beyond your power of teaching hand him over to a kangani: he may be more successful, but your own efforts at teaching are frequently attended with more success than the kangani's. Try your best to get the work out of your coolies without having to punish them by giving half name or marking them "sick," as "no name" is called.

An assistant who looks after his coolies well, very rarely has to mark them sick or even half name, unless under very exceptional circumstances.

ERTATE BOOKS.

Work quietly, allow no loud talking amongst your field workers, the only loud tone of voice heard is that of the kangani or conductor, reminding the coolies to do something they are apt to forget, or not to do something he may have just discovered has been done amiss. Your duty will be to keep what is called a Pocket Check-roll for enrolling the names of those at work and from it daily enter all the names into what is called the large or office check-roll. It is an easy task balancing the labor journal and check-roll immediately after work, but becomes a very difficult one if left for a day or two, and there are other objections to postponing making up the check-roll till "the morrow."

In addition to your labour journal which shows the labour distribution of the day, you ought to keep for your own edification, if not asked for by your P. D., a Field Journal. The book should be ruled, but you make cross columns for the various fields as they are known by their averages, and a column for the day's total. Opposite each day and under the respect

* In the British Parliament the Speaker's mysterious threat of "naming names" strikes terror to the soul of members. On estates the great punishment is just the reverse: to deprive a cooly of his name in the day's check-roll. No name means no pay.—ED. T. A.

ive headings, enter the number of pounds of tea leaf plucked (or boxes of coffee cherry gathered) off that field. You will find this very useful information as you go along; and it will fully compensate you for the very little trouble it has caused you. Have also a column for number of coolies employed plucking and see that it agrees with your journal, and one to record the total average number of lbs. gathered per cooly per diem.

In the same field book a few pages further on have a page ruled almost similarly, for the purpose of recording the month and number of coolies employed pruning each field during that time. You will find this useful for reference as well as to afford you at a glance information as to what your pruning has cost, and be of some assistance to you in estimating the cost of pruning tea in the future.

WEEDING.

It will also be your duty to see that the weeding contractors do their work properly, and let me tell you there is no work on an estate more liable to be scamped than weeding, and generally it is the most expensive. The estate you are going to, we will suppose is weeded once a month, still it is not clean and the contractors are making very little if any profit off their contracts, so that much of the assistant's time is spent having frequently to visit the different weeding contract gangs. I am quite aware this is often the case, but think the contractors should pay for their own overseer.

Thus if your estate is 800 acres, and weeded by contract at so much per acre per mensem, it is an easy matter getting the contractors to agree to a reduction of three or four cents per acre, and you appoint one of yourselves on the sum obtained by the reduction, to be overseer of all the contracts. His duty will be to visit every contract, daily examine the previous day's work, and make them do it over again if badly done. See that the coolies have the regulation weeding tool, whatever that may be, that each of them have a cooty sack to put the weeds into, and that one or more large sacks are being used for receiving and carrying the weeds from the cooty sacks to the weed depot, that none are missed, or allowed to lie amongst the tea or in heaps on the roads. The weeds ought to be transferred from the cooty sacks to the large sack and not thrown on the road in a heap, to be gathered afterwards. At 4 p.m. the weeding overseer reports to you in the presence of the kanganyas, and on the work generally the number employed on the various contracts, which statement you enter in your check-roll.

If you find that with monthly weeding with the close supervision of an overseer, and your own periodical visits that the estate is still far from clean, then insist on the contractors weeding the same ground three times in two months for the same money as allowed for weeding twice in two months. It is only a matter of a few extra coolies the first month or two; afterwards the work becomes lighter and contractors will reap a profit where formerly they had a loss.

Factory work. I'll leave your P. D. to give you the necessary hints: it is so much easier doing so on the spot.

But if I haven't tired you out, I would strongly advise you to carry an umbrella and use it as a protection from the rain; it is more wanted than a waterproof coat is for protecting you from rain. Never go out without a sun hat, while the sun is up, no matter whether it is shining or not, even during a cloudy or wet day you are liable to get headache, fever or sunstroke.

Confine your drinking to the bungalow, and unless you are on one of the most highly favoured estates as regards climate, have the water you drink boiled as well as filtered before using. Don't mix anything strong with your water. It will be quite time enough to do so when the doctor orders you; meantime the squeeze of a lime in water with a little sugar is quite enough when you get in tired and must have something before breakfast. Now, as a rule, is the time for your bath, and a very great luxury the bath in Ceylon is to a new arrival. The big plunge or the spout of cold water, the very thought of it makes

me wish I were young again. But be careful not to stay in too long; one can have too much of a good thing even. Enjoy your bath and get into dry clothes as quickly as you can, for by this time I am sure you will be ready for breakfast. Two hours are usually allowed for breakfast, but if you have been unable to spare the time for a bath before breakfast, don't neglect to change your flannels: they are bound to be damp, and to sit damp in Ceylon in most bungalows, means catching a chill, and a chill is frequently the first stage of nearly all the ailments planters are heir to.

After 4 p.m. you should have a cup of tea or coffee (if you can get it) and if very peckish a little bread and butter but nothing stronger.

Water is also the safest and best beverage to dinner in youth, and should be persisted in unless otherwise ordered by a doctor whose medical advice on all other points you would equally value and act up to.

If cards happen to be introduced after dinner and you are invited to join in the same to make up the set, if money are the stakes, don't be afraid to decline to play for money. Stand firmly by your home training and you will never regret it.

Make your little bungalow as neat and comfortable as your means will permit, having a few pictures to enliven the walls, but only of such a nature as your sister or mother might look on and admire.

Do not forget the friends at home, they are always anxious to hear from you. To write a letter home does not take many minutes after it is commenced and the postage is now within the means of all, so there ought to be no excuse for omitting to write at least twice a month to those who have cared for you, probably from infancy. If you have not brought a few books with you, consult some of the Colombo price lists, you have Cave & Co., the Colombo Apothecaries' Co., or for practical instruction, the *Observer* Office list containing all sorts of books useful to planters or your P. D. will be glad to lend you if you are careful of, and return them. Make it a rule not to keep a book long and return it when read.

However small your income may be, live within it. Pay as you go, or at latest during the following month.

Do not order anything unless you are certain you will be able to pay for it the following month. Credit has been the curse of many a young man in Ceylon. My parting advice to you is "don't get into debt."—Well, good-bye, I must be off—shall be glad to hear from you, how you get on. You know my address.

[We shall be glad to receive suggestions, or additions to above, and to put all in our "Planting Directory" so as to be easy of reference in a permanent form.—ED. T. A.]

COCONUT CULTIVATION.

(By an Old Planter.)

DIGGITIVENESS: A REVOLUTION IN CULTIVATION.

The coconut planter, who turns over the whole surface of his field, to a depth of, from six to eight inches, or one mamottio, may fairly expect the following effects:—

1st. That the withering and aeration of the newly exposed surface will aid in rendering soluble any inert organic matter it contains.

2nd. That breaking up and loosening the soil enables the roots of the cultivated plant to extend more freely, and consequently more quickly.

3rd. That one digging is more efficient, in cleaning foul land, than ten surface weedings.

4th. That the natural herbaceous cover of the soil, when turned in, acts as manure, in the course of its decomposition.

5th. That in the course of the season, a richer, cleaner and closer pasture is produced, than that destroyed by the digging.

6th. That the cultivated plants will develop more in the subsequent twelve months, than in any previous twenty-four.

Number one has been accepted as theoretically probable; all the others have been established experimentally, with results, far beyond original expectation. Plants with a head of from ten to twelve leaves, and that had not begun to show stem, began to flower in from twelve to fifteen months, and at the end of two years carried crops of from forty to over one hundred nuts. Plants whose longest leaves did not exceed six feet, and that had made no visible progress for two previous years, two years after the digging had heads up to sixteen leaves, the last fully developed eighteen feet, and beginning to show stem. Cases where simple digging has been complicated with the application of manure will not count in this argument though they prove that manuring and digging combined yield results almost marvellous. On young trees that were just getting their stems clear of the ground, an expenditure of 27 cents was incurred, many of them flowered within a year, most of them within a year and half of the application; they are carrying crops seldom seen except on old trees standing on the choicest spots of soil.

It is a fair inference from such results, that if, instead of beginning in the seventh year as in this case, digging were inaugurated in the first year, and the circles widened as the roots extended, several years would be gained in the time of bearing especially if the diggings were supplemented with two cents worth of nitrogenous manure. About thirty-six cubic inches of cattle-shed manure has been found very useful in bringing forward supplies. There are five conditions that either singly or in various combinations prevent coconuts from bearing before the end of the seventh year:—

The 1st of these retarding conditions is a feeble slow-growing plant. The remedy is to take it out, and replace it with a healthy one.

2nd. A stiff compact soil, through which the main roots make only slow way, and branchlets carrying the feeding points still slower. The remedy is to break up such soil, by digging, as often as may be required.

3rd. A very poor soil, that is deficient in the necessary elements for the development of the plant. This may be remedied by the application of suitable manure, but a better plan is to avoid planting such land.

4th. A periodical deficiency of moisture. For this there is no generally applicable remedy, but a pulverized soil resists drought better than an unbroken one, and so far the evil may be modified.*

5th. The neglect that permits other plants, as jungle and lantana, to interfere with the development of the plant, both above and below ground. The remedy for this is the complete extermination of every plant that has no right in the ground allotted to the coconut by bearing no economic value to balance the ill it does.

If the land be opened on the goyia system it will be a direct saving of expense to the land owner, of nearly R30 per acre, and his share of the crops may be worth from R10 to R20. The goyia system being a merely depleting one it is very doubtful whether its adoption is any gain in the end. The goyia's labour is paid for out of the fertility of the land,

and it seems probable, that the retention of the elements so removed would benefit the permanent crop more, than the immediate gain would compensate, especially as the goyia leaves much work to be done, that could be more beneficially performed at an earlier period, and at less cost, than it requires ultimately.

Coconut cultivation would be a much more desirable investment could it be combined with some other cultivation, that would pay independently, for the early breaking up of the soil and for such manure as it needed on its own account. It seems, however, hopeless, to discover even one product that will meet those conditions. Everything produced by native labour, for native consumption, is out of court, to one who pays for labour at the current rate of wages. There then remain only the markets of the world for such products as they absorb. The prospect here is not encouraging; the essential oils are clearly overdone; tobacco is objectionable for its exhausting powers, and few coconut lands will grow it at all. Cassava and arrowroot are in the same case as essential oils, and could only pay on a large scale, with a costly manufacturing plant, which with the prices now ruling it would be madness to set up. Curiously enough, in Ceylon, where the arrowroot plant grows freely and yields largely, the lowest price is four times as much as the wholesale price in London, and in the druggists' shops twelve times as much. The local demand, however, is too small to encourage anything being done with it on coconut estates, as 20 acres of cultivation would probably bring down the prices to a non-paying point in the local market, even were well-to-do colonists not so preposterous as to prefer paying five or six hundred per cent more for stuff that has been through the polluting hands of an English tradesman, than for a pure locally produced article. Ginger selling from 6d to 8d per pound is encouraging, but it requires a special soil, and costly culture, and is a precarious crop; it will not, therefore, meet the conditions of the coconut planter. It is just possible that chillies might be grown, and placed in the London market, for the price they command there, 20s to 25s per cwt., but on their own merit the cultivation is not promising. The coconut planter will naturally decline a secondary culture, risking direct loss on the labour and manure used, and promising only remote and indirect gain in benefit to the permanent plants. There is one other minor product which could be cultivated on young coconut estates, with great advantage to the cocoons; but its merits are little known to the local public, and it is the local public on which the grower must chiefly depend. The cush-cush yam requires a tolerably good soil, pulverized to the depth of a foot, heavy manuring, and a forest of long poles to run on. The cultivation is therefore a most costly one, and has hitherto only been tried on experimental patches; but if it were found to sell readily at a paying price it would no doubt be gone into largely. Those who are acquainted with it admit it to be not inferior to the best potatoes, and some people even prefer it to that universally approved tuber. This plant was only introduced to the Western Province a few years ago, and the only fact fully ascertained is its refusal to respond to anything short of a high and costly cultivation.*

* For two reasons; a free open soil is not only saturated by rain, when it falls, and permeable by dew, but is fitted by capillary attraction to draw on the reserve stores of moisture in the subsoil, when the surface fails to be visited by rain or dew.—Ed. T. A.

* Where did it come from and what is the origin of the queer name "cush-cush"? Is it just the West Indian yam? or a local variety? The Jaffna purple yam is a magnificent root, very tasty, especially when butter is added, and we should say it must be very nutritious.—Ed. T. A.

TEA SUBSTITUTES AT THE CAPE.

In reference to the articles on Tea and Coffee substitutes, now appearing in the *Gardeners' Chronicle*, the following notes concerning this colony may be of interest.—

Cyclophorus genistoides, Vent., is the commonest Bergthee of the western province. It is used partly as a mere substitute for ordinary Tea, and partly with an idea that it is good for coughs and difficulty of breathing. Its infusion is sickly, sweetish, and has a somewhat astringent after-taste; it is not unlike a sweet solution of liquorice. The liquorice flavour is, however, much more evident in the several *Helichrysa* used under the names of Hottentot, Bosjesnaag and Kafir Tea. *H. undifolium*, Less., *H. capuliferum*, Less., *H. Leipoldum*, DC., are all employed without much discrimination, and the vernacular names change about among these species. I have seen *Geranium lacarnatum*, L., gathered as a Bergthee on Boschberg, behind Somerset-East. *Mouronia ovata*, Cav., biflora, DC., and *Burkiana*, Pl., are only used medicinally in cases of diarrhoea, but are less prized than the allied *Pelargonium reniforme*, *Bot. Mag.* The report of *Cassia mimosoides*, L., being used at the Cape as a substitute for China Tea is surely a mistake. The only *Cassia* I know of as in use here is *C. tomentosa*, Lam., a naturalised plant, common in farm gardens and about villages; it is a capital substitute for Senna, with or without the accompaniment of Engelsehe Zout, or Epsom salts, among the coloured servants. I should doubt if any *Cassia* is a Tea in any other sense than "Senna Tea."

The Malays of Cape Town are great on native Teas; they drink lots of infusion of "Als," *Artemisia afra*, Jacq., under the idea it is good for the "peus,"—Anglice, paunch—but, I believe, partly for the peculiar huzziness of brains which it causes, something like the effect of strong tobacco on a smoker accustomed only to golden leaf. I have often been told that it makes you feel "moodi,"—that is, nice—a sufficiently suggestive term for those who are forbidden to indulge in the moodi-ness that comes of Cape brandy. *Leyceera gaspalioides*, Less., is brought down from the Lion's Mount every day in the season to make "G elshonneljus-thee." It is credited with diuretic properties in cough and catarrh, but is used often merely as a herb drink.

My warby friend, the Rev. A. G. Hottasch, of the Mission in Mexico at Goodwood, sent a collection of thirty-three plants used medicinally or as herbal drinks by the Hottentots and off-colour people on his estate, to the Colonial Exhibition in 1886. Whether they ever got there, or, like so many other contributions, were dropped somewhere, I cannot say. But they were submitted to me for identification, and I published them with Mr. Hottasch's notes on their use, in the *Volksblad*, December 29 1885. A translation could no doubt be made for anyone interested in Cape herbalism.—P. MACDONALD.—*Gardeners' Chronicle*.

PEARL FISHERY AND WATER TELESCOPES.

SIR, I know the instrument "Water telescopes" of old. A long tin funnel 2ft.—3ft. long; with a piece of plate glass at the lower end about 8 inches wide, the upper end being about $\frac{1}{2}$ the size. We used to use it to look for fresh water mussel in the Ty; one would row the boat over where the mussel beds were supposed to be; and another would lean over the stern with the telescope the glass end was put into the water about 10 in. just clear of the ripple and you could see the bottom of the river plainly, in spite of the dark peaty colour of the water. When we saw the mussels we used to fish them up with a long stick with a couple of pieces of iron fixed at the end. The mussels contained small pearls, so you see the water telescope has been used at a pearl fishery before now.—I am, yours faithfully,
J. MAUDSLAY.

June 9th, 1891.

—Local "Independent"

COCOA IN THE LONDON MARKET.

A late Ceylon Planter writing from Home says: The very high quotations for cocoa which you had at the beginning of April, were not really obtainable. They were merely based on a single sale, at which two buyers were bidding recklessly against each other. No further sale took place at the same rate.

The brokers, however, think that the present rates, about 122/ for every good sample, are likely to be maintained for a time. They informed me, that the bright red outside colouring is the most important thing. The Spanish buyers, for instance, value cocoa solely by its outside colour. I was not aware that cocoa beans were eaten as dessert. It appears that they are so used in Russia, and they are exported from London, to be eaten in Mexico.—Local "Independent."

THE DISEASES OF THE COCONUT TREE.—The paper by Mr. M. C. Potter on this subject, which was announced for reading at the meeting of the Linnæan Society on May 7th, was not reached in consequence of the length of the communications which preceded it. It stands over therefore until June 4th.

THE PROPOSAL FOR FORMING A CEYLON SYNDICATE FOR WORKING TIN IN PERAK is taking definite shape, and that the arrangements are now only awaiting the arrival in this country of Mr. Campbell, who will finally have the determining of one or two points. The result will certainly be the appointment of Mr. F. D. Mitchell as manager of the concern, the leading men in it being Messrs D. Reid, H. K. Rutherford, and Sir G. H. D. Elphinstone. I understand that Cecil Smith takes a deep interest in the enterprise, which will have all the aid and encouragement in his power to give.—*London Cor. Local "Times."*

COFFEE AND TEA LANDS IN TRAVANCORE.—A Royal Proclamation has been issued giving notice that in consequence of large areas of land taken up for coffee cultivation having been abandoned by the proprietors, a tax of two annas per acre will be levied on all lands acquired for coffee or tea cultivation whether such lands be under cultivation or not and that it is open to proprietors to renounce and resign to Government the whole or any portion of such lands in which case the tax upon the relinquished portions will be remitted.—*Cochin Western Star*, June 6.

AN ARTIFICIAL SUBSTITUTE FOR QUININE.—As if to add the very last straw to the cinchona planter's back, the chemists have at length successfully accomplished the work so long set before them of manufacturing artificial quinine, or a sufficient substitute for the same. For the details we refer to an article in our *Tropical Agriculturist*; but the *Chemist and Druggist* may well add the remark, that the discovery comes too late to be of any commercial value since it does not even pay now to cut down the Cuprea bark in the South American forests. Still here is one more reason why we need never expect to see cinchona bark again rule high in prices.

FALL IN TOBACCO SHARES.—We learn from our Amsterdam correspondent that an extraordinary decline has taken place during the week in the shares of the Dutch Tobacco Companies. For instance, the Deli Company's shares reached 80 per cent., while the Deli Batavia Company shares are 113 per cent. lower. The shares of the Senembah Company are quoted 250 per cent., against 296 per cent. last week, or a drop of nearly 50 points. The reason of this fall, notwithstanding the high dividends declared, is ascribed to the fictitiously high rate to which these securities have been driven up, and further to the unsatisfactory quality of the arrivals of the present year's crop, for which lower prices have had to be accepted.—*L. and C. Express*, May 16th.

GREAT RETICENCE is observed in reference to the United Planters' Company of Ceylon by those interested in it. The same may be said of another rubber company forming for the purpose of acquiring a property in your island. I saw the skeleton prospectus the other day; but, as it was originally devised for the acquisition of a large property since acquired by the Ceylon Tea Plantations Company—Yorsted—it can not be mentioned as actually in existence, though other properties are mentioned as likely to be acquired. The initiation of the project is due to Mr. Grierson, of Messrs. Geo. Steuart & Co., and the prospects only await certain additions and simplifications in order to place it before the British investing public.—Local "Times."

TRADE OF THE SOUTH AMERICAN REPUBLICS.—At a meeting of the London Chamber of Commerce, yesterday, Admiral H. D. Grant read a paper on the "State of Trade in the South American Republics," and in the course of his remarks expressed his surprise at the almost entire absence of English firms from Monte Video, and the decrease of the number in Buenos Ayres. The disappearance of old established houses he attributed to the growth of direct trade with England. Admiral Grant considers the trade prospects gloomy, having his estimate on recent steps taken in taxation and currency matters, more especially in the Argentine Republic and Uruguay.—*Chemist and Druggist.*

NIJER GUM ARABIC.—In a paper on a trip along the Niger and Benue rivers read before the Royal Geographical Society on Monday, reference was made to the town of Yola, on the Benue river, as the most important trading centre in that region—tiro, gum, harao, and gum copal being the local products brought there by the natives in exchange for Manchester goods. The gum arabic referred to is the Niger gum, which has during the last two years arrived on the Liverpool and London market in such large quantities. The gum is probably obtained from the Muri range of Mountains, north of native villages of Lau, Dalti, and Djon, on the Benue river. With the establishment of more regular trading communications with Niger Basin, Niger gum is, perhaps, under certain circumstances destined to become as important an article on our produce markets as the East Indian gums are at the present moment. Yola, the shipping port, is near the extreme eastern edge of the Niger Company's present sphere of influence.—*Chemist and Druggist*, May 16th.

DEHIOWITA DIVISION, KELANI VALLEY, May 18—Very monotonous weather here. There was a terrific thunderstorm here on Friday evening accompanied by torrents of rain. Saturday forenoon was fine, but rain came on again in the evening and continued steadily to pour all night, and all yesterday (Sunday). Today the rain came on again at 2 p.m. obliging me to knock off the coolies. I have hardly known such a persistently rainy monsoon. The electrical phenomena too have been remarkably severe. I append rainfall record since rat of this month as follows:—

	inches,		inches
May 1	.. 17	May 9	.. 30
" 2	.. 13	" 10	.. —
" 3	.. 40	" 11	.. 10

Do January	1891... 693
Do February	" 54
Do March	" 1420
Do April	" 2080
Rainfall this year to date 6247

A COCOA STORE BURNED DOWN.—We learn that one evening last week the large store at S. S. Anga estate, Matue was destroyed by fire. It is estimated that several thousand rupees damage was done on the occasion, and while the origin of the fire is unknown we are sure no blame can attach to Mr. Leslie F. P. the energetic manager of the estate.—Local "Independent."

A CEYLON PEARL OYSTER IN LONDON.—The Loudon Queen to hand by the mail contains an account of rather a novel shop-window exhibition which it says is at present exciting a great deal of curiosity in Bond Street. The exhibition, so it is said, consists of a perfect Ceylon pearl-oyster, in which are no fewer than seven pearls in a cluster. The pearls are detached and are of excellent appearance, one being valued at £40 sterling. The oyster has been preserved in spirits. We do not know how it got there; but we presume the oyster is one of those fished at the last Fishery. Still, no clue is given as to who sent it, and we should hardly think any of the native traders would have recognized what a curiosity it would be to the folks at home. However, the pearl oyster is there, affording yet another advertisement for our island, and the little oysters it is said draws people by the hundred.—Local "Times."

TEA IN TRAVANCORE.—Mr. Forbes Laurie, who returned from Travancore about three days ago, as greatly impressed, we believe, with the excellent prospects before Travancore tea planters, and in a small way there is no doubt that Travancore will be one of the future rivals of Ceylon, though the acreage under tea will never enable it to be a formidable one. The soil is good, and the tea though most of it is young, has done excellently so far, young tea 3 years old giving 400 lb. an acre, while labour is plentiful and cheap, the wages average being 25 cents, and there being no difficulty in recruiting. The coast advance system has not proved the bane to Travancore planters that it has to Ceylon ones, and from all accounts Travancore is a sort of tea growers' paradise. Roads are not so numerous or good as they are in Ceylon, but transport to the coast is cheap and plentiful while the estates are easily worked. They are for the most part at a height of from 2,000 to 3,000 feet above the sea, though a given elevation is said to be slightly warmer than the same elevation in Ceylon at least on the western side of Nuwara Eliya. There are one or two Ceylon planters already in Travancore and other Ceylon men have interests in the district. The only thing against social life there is that the estates are at some distance from each other, and communication is not so good as it is in most of the upcountry districts of Ceylon; but from an investor's point of view Travancore leaves, it would seem little to be desired.—*Ibid.*

A NEW PLANTING COMPANY.—I heard on good authority that a company has been formed to open up the blocks of forest land in Bamberabatuwa belonging to Mr. J. Dent Young and others. These blocks, Hapugastenne and Watawedowo, aggregate over 2,500 acres, and will form a very fine property as they are situated at a fair elevation and in a fine climate for tea cultivation. They were originally purchased for the purpose of cultivating coffee in the forties, and a small portion was opened, but they were abandoned in the crisis of 1848. Mr. J. Dent Young originally selected the land, I believe, and opened it. It is still to the front, although one of the original pioneers of coffee planting. The Government are also advertising for sale on the 9th June a number of lots of land suitable for tea, cacao, etc., and these lots include some of the finest land remaining in Government hands in the hills. This district is as yet little known though only 2 or 3 miles south of Maskeliya and about the same distance north of the Panundulla-Ratnapura road. The district will now, no doubt, be rapidly opened up, as the new company and the purchasers of the Government blocks will open up the roads cut over 40 years ago and which require comparatively little done to them to put them in good order. There are over 6,000 acres of land in private hands, well suited for the being properties purchased over 40 years ago, and with roads to help, these will be opened up. The outlet for the Bamberabatuwa district will be Ratnapura.—*Cor.* Local "Times"

SOILS AND THEIR PROPERTIES.

From a recent report of numerous investigations of soil from the Californian vineyards and orchards by Professor E. W. Hilgard, the following summary of the general conclusions should prove of value and practical use to all gardeners and horticulturists.

First, in no case has any natural virgin soil showing high plant-food percentages been found otherwise than highly productive, under favourable physical conditions. But, on the other hand, the reverse is not always true, for the simple fact that heavy clay soils, rich in plant-food may advantageously be diluted with arid sand several times over, thereby increasing instead of diminishing their productiveness, because of improved physical conditions. This fact is abundantly exemplified in the daily experience and practice of gardeners.

Of course there must be a limit to the favourable effect of such dilution, even if effected by means of sand, which renders the soil more readily penetrable by roots.

In the case of dilution of heavy clay soil by sand, not only is there a necessary limit beyond which plants cannot make up by greater spread of root for the diminished amount of available plant-food existing within a given space, but it is obvious and abundantly exemplified in Nature that this limit is materially influenced by the habit of the plant root-system, and especially by its ability to develop abundant root-hairs. The better provided it is in this latter regard, the greater will be its ability to utilise plant-food spread through an extended space in a diluted form.

The presence of one substance in the soil often exerts a material effect upon one or several others. Among these, the presence of an abundant supply of lime seems to be the most common and potent; for the evidence that, in presence of much lime, smaller proportions of potash and phosphoric acid are adequate for profitable culture, than when lime is scarce, is overwhelming. Most potent of all appears to be the co-existence of large supplies of lime and of humus. On the other hand, investigation distinctly shows that the presence of much clay necessitates a large supply of the active plant-food ingredients than is necessary in light or sandy soils, simply, perhaps, for the reason that roots cannot penetrate clay as minutely and abundantly as sandy ones.

These facts lead us to affirm that, in calcareous soils, minimum percentages of mineral plant-food will suffice for the purposes of maximum crops, even under the most exhaustive culture.—J. J. WILLIAMS, Harpenden.—*Gardeners' Chronicle*.

QUININE OBTAINED SYNTHETICALLY.—News come from Paris that quinine has been obtained synthetically by M. M. Grimaux and Arnaud, the former professor at the Ecole Polytechnique, and the latter the successor to Chevreul. The base cuprein contained in the *Remijia pedunculata* is treated with sodium, and after further processes, quinine "absolutely identical" with that obtained from Cinchona is produced. As the *Remijas* are closely allied to Cinchona and the bark is used as a substitute for that of Cinchona in Brazil, there may not be any great value in the discovery, except that it may lead to the production of other bodies.—*English Mechanic*.

SUPERIORITY OF CEYLON CARDAMOMS.—The *Chemist and Druggist* of 23rd May contains a report of a lecture delivered in Berlin by Mr. H. Holbing of London, on "London Drugs: their Varieties and their Substitutes." We shall give this in full in the *Tropical Agriculturist*, but quote here what Mr. Holbing said about Ceylon cardamoms:—

Mr. Holbing showed seventeen different samples of cardamoms, and observed that those from Ceylon, like nearly all other drugs exported by that island, were carefully bleached and packed. The finest of his specimens was grown from seed originally obtained from Mysore, in India, and represented about ten times the value of the most common unbleached Telloherry fruit.

TIMBER SPECIMENS FOR THE CHICAGO EXHIBITION: A HINT FOR CEYLON?—According to *L'Art dans les Deux Mondes*, "a splendid collection of wood specimens" will be sent to the World's Fair at Chicago from Jamaica and the other West Indian islands. "These specimens . . . will have the appearance of bound books, one cover of which will be polished, while the other will show the natural aspect of the wood, and the back will retain the bark and will bear a tablet giving, in gold letters, the name of the species. This 'botanical library' will be accompanied by notices explaining the localities where the tree is found, and the qualities and uses of its wood."

PRESERVING FRUIT.—A Californian paper says:—"The liquid in which the State Board of Trade has so successfully preserved fruit for exhibition purposes is prepared as follows:—Thirty gallons of filtered water are placed in a barrel, and on the water is placed a tin pan containing 25 cents' worth of sulphur. The sulphur is set on fire and the top of the barrel is covered with a piece of olefin, so as to retain the fumes. When the sulphur ceases to burn the covering is removed, allowing the supply of oxygen in the barrel to be renewed, and after stirring the water the sulphur is again set on fire and the top of the barrel is again covered. This operation is repeated until the sulphur will no longer burn, when the water is ready for use. Not only are fresh fruits preserved in this water, but where decay has set in it is completely checked, and withered fruits have their plumpness and colour restored. All of the fruit in 'California on wheels' has been treated in this manner, and there are jars of fruit in the rooms of the Board that were prepared over a year ago, the fruit still appearing as if but plucked from the trees."—*Adelaide Observer*.

MUSK PLANT FIBRE.—At the meeting of the Central Louisiana Agricultural Association last Wednesday evening, Mr. J. L. Beroard exhibited a specimen of fibre which was secured from the musk plant that compares favourably with any we have seen for the manufacture of bagging or rope. The seed of this plant was secured by Mr. Bernard from South Carolina. He says it resembles very much the *okra* and cotton, and is cultivated in the same manner. The seed are for flavoring purposes and command a good price. The fibre product was discovered by Mr. Bernard while having cotton stalks thrashed off his land. When the stalks of the musk plant were hit with the flying pole the bark peeled off, leaving the fibre clear. After remaining in the field all winter, exposed to the bad weather, the fibre was found to be very strong. Mr. Bernard says it will grow from the ratoon, the same as sugar cane.—*Indian Agriculturist*, May 30th.

COFFEE FROM BENDERAI (*Hibiscus esculentus*).—Captain Henry Willett, the pioneer ramie grower of Louisiana, who for many years has grown various fibrous plants at his place just below Algiers, recently exhibited a very aromatic ground coffee, which he said "was obtained wholly from roasted *okra* seed." This substance had, during the last American war, been frequently used as a substitute for coffee. It not only has the same flavor to smell and taste as coffee, but it is thought the same tonic effect. Whether so or nor it makes a cheap and agreeable substitute for coffee, and as such it should be utilized. It will pay to raise *okra*, because every particle of the plant can be utilized—the young pods for food, making the most delicious pickles;* the ripe pods producing a coffee bean; the bark a valuable fibre, while the woody portion makes excellent paper stock. This common and little (hitherto) prized Southern plant may yet exceed cotton as a wealth producer.—*Indian Agriculturist*, May 30th.

* The *benderai* is an excellent vegetable, but we have never seen it pickled in Ceylon?—ED. T. A.

Correspondence.

To the Editor.

THE WEIGHING OF TEAS IN LONDON :—
CUSTOMS REGULATIONS TO BLAME.

12, Great Tower St., E. C. London, May 22nd.

DEAR SIR,—Your *Overland* issue of 28th April containing letters and observations about the taring of Ceylon teas in London and loss in weight seems to call for some comment on this side. I strongly sympathize with estate owners who like myself are victims not of a gang of thieves and swindlers as some of your correspondents suppose, but to an iniquitous system of weighing teas imposed on us by the Customs Regulations. But how can they be altered? Quite recently the Indian and Ceylon Associations took the matter up as regards weighing tea to the ½ lb, and the Customs expressed their willingness to carry this out and agreed to it. A strongly supported meeting of the tea dealers dead against an innovation which would have been so important to the shippers managed however to obtain the suspension of the new decree, and no reform in this direction at present seems possible. The matter of the tare is even more disadvantageous to us; and owing probably to the greenness of the wood used for tea packages which causes them to dry and shrink in transit, I fear under the present system we shall all have to put up with periodical severe losses in weight.

Your short leader, sir, on page 489 Vol. X. fully explains to your readers that no outsiders have any responsibility in the matter, and I would further point out that no broker in London would allow his client's tea if sent in boxes of under 23 lb gross to be taxed 1 lb extra for draft. In the case referred to, it stands to reason that the 1 lb loss per package was either from the tare being slightly above the even number of lb, or from the tea weighing below the even number of lb, or most probably the loss was caused part by short as part by extra tare. It is a mere coincidence that the loss on 81 packages should be 81 lb, and the 1 lb draft has not been taken from each package as evidently supposed by your correspondent.

The loss in tare on a box, although it would show a much heavier percentage, would be just as likely to occur as on a chest, and to the same extent if the tare was just over an even number of lb. For instance a chest of 80 lb with a tare of 24 lb ½ oz. would be called 25 lb tare=loss 15 ½ oz.—a box of 28 lb with a tare of 9 lb 1 ½ oz. would be called 10 lb tare=loss 15 ½ oz.

The actual system of weighing and the security we have against any unfairness have so frequently been referred to in your columns it is needless to refer to them again, but the clearest letter on the matter that I can lay my hands on just now is that in your *Overland* issue of 16th Feb. 1889, signed "Bonded Warehousekeeper." Certainly to my mind the most important guarantee in the interests of shippers is that tea being an article of consumption subject to duty, we may be quite sure the Customs authorities take good care that the weight shall be in noway minimized. One of your correspondents asks who gets the tea that is lost to the shipper. The answer to that is the grocer or retail shopkeeper, who breaks up the package that he has bought from the wholesale dealer, always calculates on extra weight beyond his 1 lb draft, and by the system under discussion may be tolerably certain of getting it.

As regards sweepings. Any spillage that is made in drawing samples or otherwise has to be made good by the dock or warehousekeeper not for the benefit of the importer whose weights have already been defined by the clerks of the Customs and warehouse before samples are drawn, but for the benefit of the buyer who takes care to see he gets what he is entitled to. As for imagining any collusion between those authorized to see the tea weighed and the dock or warehouse clerk it would be quite impossible; and if it were possible it would mean a conspiracy so vast and ramified that nothing in modern times has ever approached it, not even the Tammany Ring.

Subjoined is a comparison of four shipments from two estates in Dikoya comparing loss in weight of factory-bulked teas with those bulked in London, and from which may be inferred that factory bulking owing to the system of taking an average tare causes a greater loss in weight. With Indian teas I am told the loss in weight in the higher grades is always far heavier than in the lower grades and it seems it is the same with Ceylon teas. On this point at present I can offer no opinion.

Apologizing for trespassing so much on your space, and hoping that the importance of the subject will plead for me, I remain, dear sir, yours faithfully.

JOHN HAMILTON.

23, Crotched Friars London, E.C., May 21st.

DEAR SIR,—Your paper of the 30th ult. contains numerous letters from tea planters, charging London brokers and others with wholesale robbery of tea entrusted to their charge. I think it is disgraceful on the part of the writers of the letters to make such a charge after the repeated information they have received in London showing how the discrepancy arises.

In the first place packages are weighed and tared by the Customs to the pound, viz if a package weighs 70 lb 15 oz it is called 70 lb., the loss to the planters being 15 oz. If the tare of the package is 20 lb 1 oz, it is called 21 lb., also a loss of 15 oz. I was called upon by a client to give an explanation with regard to the difference between Ceylon and London weights, and to make the matter plain, I weighed and tared a shipment of tea as under.

(Copies of which I enclose for your inspection or for insertion in your paper if you think necessary.)*

In the first instance, they were weighed and tared by the Customs, and afterwards weighed and tared to the oz. By weighing and taring to the oz, you will see that the weights exceed the Ceylon weights, which shows that the weight of tea given is correct; but under the Customs regulations it is not possible to agree the weights with out they pay attention to the making up of the packages to meet the Customs regulations, viz. gross weight 2 or 3 oz over the even lb., and the tare 2 or 3 oz. under the even lb.

	lb.	oz.	
say	19	13	Tare
	50	5	Tea
	70	2	the Customs calling that
70 lb.	Gross		
20 "	Tare

Tare of box	10	14
Tea	17	4
	28	2
	lb.	
	28	Gross
	11	Tare
	17	Nett

The Customs calling that

and no draft of 1 lb. allowed.—I remain, yours truly,

ROBERT JONES.

DESICCATED COCONUT.—The manufacture of this article was only commenced a year ago, but it has now evidently attained a very propitious as the quantity shipped is nearly 100 per cent more than it was originally. The original spot where it was manufactured was at Veyangoda, and its manufacture was followed by Messrs. Vayassent & Co. at Maradua. It now appears that Messrs. L. E. H. Dages & Co. have everything ready as regards machinery and fittings at their mills at Colpetty to commence a very nice desiccated coconut as well, while Messrs. Akbar Brothers have about 8 desiccators now being constructed for erection at their large coconut estate in the Negombo district, followed by another native, who wants to start "an opposition shop" at Veyangoda. It looks like good times for all coconut proprietors and planters.—*Cor. Local "Independent."*

CEYLON TEA PLANTATIONS CO.—By the present mail you will receive a report of the proceedings at the Annual Meeting of the Ceylon Tea Plantations Company held on Wednesday last, the Directors' Report having gone forward by the previous mail. The address of the Chairman will be read with interest, not only by Ceylon shareholders and planters generally, but by Indian planters, as conveying information on a variety of points in which all are concerned more or less. You will observe that Mr. Hill is thoroughly satisfied with the Company's recent additions to its long roll of the estates, the latest of which was completed not more than a week ago. The furlough account which has just been opened in the interest of the Company's works affords a highly commendable illustration, and though the annual amount anticipated as being the cost of a new estate of £600, it must be remembered that this has to cover the provision for leave to Europe for the superintendents of twenty estates. The Chairman's opinion of the condition of those properties, and of the stability of their factories, is undoubted; the latter are declared to be of the most permanent description, well built, well designed, and adapted for economical and efficient working. Whilst no money has been expended in putting up fancy or show buildings, no outlay has been grudgingly given to the superintendents the means of making good tea. It was pointed out by the Chairman that they were enabled by their hulling and machinery not only to produce increasing quantities of tea from their own estates, but during the year to make nearly two millions of pounds of tea from other plantations, and when their latest factories are completed the Company will be in a position to turn out considerably more than four million pounds of tea annually from their own estates. During 1890 a profit of £31,000 was made from a plucking area of less than 4,000 acres. Of the company's latest purchases, the Chairman said, "Yorford, with the adjoining estates of East and West Holyrood and Ratbailokelly, form a compact block of over 1,700 acres. The total cost to the Company will be £54,000. In a few years this ought to be a very fine property, as it has great advantages in climate, soil, class of plant, proximity to railway communication, and water power. The old tea on Yorford and East Holyrood shows what we may expect the whole area to be like when it comes to the same age." Opinions will no doubt differ as to the soundness of Mr. J. L. Shand's criticisms of the Company's accounts as placed before the shareholders. For my own part I am inclined to agree with the Chairman when he replied that their report and statement of accounts were prepared for the information of their shareholders and not for that of the general public, and that any further details required by the former could always be obtained from the Secretary. It may be true, as urged by Mr. Shand and another gentleman present, that one provision of the Joint Stock Company's Act has not been complied with inasmuch as the total expenditure of the year did not appear in the balance sheet, but this will probably be remedied in the next annual account rendering, and otherwise the statement submitted met with the approval of all present.—*Local "Times."*

* Far too long to insert; can be seen at our office by anyone interested.—Ed. T. A.

A MONOGRAPH OF THE COCONUT PALM
(COCOS NUCIFERA).

ILLUSTRATED BY JOHN SHORTT, M.D., F.L.S., &C., &C.

Dr. Shortt's monograph of the coconut palm is like himself short, and tolerably innocent. A review of it, therefore, should be short, and innocent like itself. We will accept the author's statement of facts as correct, and merely point out where local experiences, opinions and practice differ from his reports.

Our author tells us, that the coconut tree grows to the usual height and fruits freely at a height of 3,000 feet in India. In Ceylon we have no thriving coconuts at an elevation of 3,000 feet, and the limit of profitable cultivation is 1,000 feet lower. Mere elevation is not, however, our rule in choosing our locality: temperature and rainfall are our measures of suitable climate. There is no temperature in Ceylon too high, and our lowest limit is an annual average temperature of 75°; our lowest limit of rainfall for successful cultivation is 70 inches more or less falling every month of the year, and our highest limit is 100 inches, for though the coconut rejoices in moisture, it detests saturation.

Alluvial flats are our richest soils undoubtedly, but the true coconut soil is 70 per cent of fine sand, 30 per cent light loam and organic matter; but the cahook soils of our undulating uplands are not to be despised, especially, as we have comparatively little other kinds to draw on. We have still people who plant clay* and swamps, to their own ultimate loss. 80 trees is the number our author allots to an acre; but whether he or the printer's devil is responsible for the error, the book says that 80 trees in an acre will stand 60 feet apart. At 60 feet apart, an acre will contain 12.15 trees to the acre, and 80 trees per acre will stand 23½ feet apart on the square. The most common distance in Ceylon estates is 25 feet on the square, or 70 trees per acre. This we find, a sound practical distance apart, for most of our soils. We know one large estate planted at 30 by 30, but it is a speciality in soil and lay of land. It is a rather loose way of treating this subject, to say, "In a well ordered plantation, the trees should be from 30 to 40 feet apart." 23½ by 23½ feet gives 80 trees per acre, and on good soils this is too close, 25 by 25 feet gives 70 (69.53), 30 by 30 feet gives 43.4 and 40 by 40 foot gives 27.47. Thus very nearly three times as many plants go into an acre 23½ by 23½ as at 40 by 40. There is no part of the coconut region of Ceylon in which the planter benefits himself by putting more than 70 or less than 50 plants in an acre.

The author's directions for selecting seed nuts are, to gather from trees 15 to 20 years old fully ripe; gathered between February and May, the largest procurable well formed, the husks dried before plucking to be lowered from the tree in a basket and to be kept for six weeks, before being laid out in the nursery.

This is a subject that has hitherto met with little attention in Ceylon. The all but universal practice has been, to select seed from a heap gathered in the usual course. It is however a very important matter, and one that deserves the most careful study. It is from clearness here that we see such inequality in our fields, inequalities not due to difference of soil, or treatment, but chiefly to fat. This author tells us, that in India (Travancore) there are thirty named varieties. In Ceylon there are a vast number of nameless varieties, very difficult to describe, but very clear to one who lives among them, and sees them daily. One tree begins to flower in its fifth year, on four feet of stem; its nearest neighbour equally vigorous, runs up to fifteen or twenty feet, and only begins to flower in the ninth or tenth year; one will have fertile germs on its first flower; and its neighbour will produce only barren flowers for twelve months; one will, within a year of opening its first flower, fall to a regular yield of 100 nuts per annum,

* In 1881 when we visited Mr. Chasertan's great manioc plantation in Singapore, he was cutting down coconut trees which, at twelve years old gave no promise of fruit. It struck us at the time that the cause was the clayey nature of the soil.—ED. T. A.

of medium size; while another close by carries from 30 to 40, very large ones, and the next in the same line, carries above 200 very small ones. Then in the size, colour, and form, of the fruit, they are hardly two trees so alike, as not to be distinguished from each other. Some of the directions given are good, some useless, and some bad. The first condition, is that the nut selected for seed should be sound and ripe, it should be taken from a strong, early, and heavy bearing tree, without reference to its age, it should be of medium size, of oval shape, with thin husk, and the green colour is generally best. The shorter the leaf stalk the better and there is no objection to lower it in a basket, but it should not be left to dry on the tree, and may be planted as soon as gathered. The best soil for a nursery bed is light loamy sand. It is not necessary to place the nuts so wide apart as one foot, or to make raised beds, but the beds should be shaded and watered occasionally in dry weather for six months. After the plant has opened its first two leaves all shade is injurious.

If in south-west Ceylon the conditions were such as to require that the plants should be shaded and watered after being planted out in the fields, we would never have had the 20,000,000 of trees we are credited with.* Shading we do not find, either necessary or useful; and to water our undulating uplands is simply impracticable. If the planting is done in the little monsoon from eighty to ninety per cent survive the first succeeding dry season. Holes can hardly be made too deep or too wide, but to bring one to two cubic feet of sand to put into each, is utterly impracticable, at a paying cost. Neither salt nor ashes are bars to white ants, and to throw a quantity of vegetable rubbish into the holes by way of keeping in the moisture is to create the nucleus of an ant-hill round the plant. The best practical plan here is to dig a hole say three feet cube, fill it in to the depth of 18 inches with surface soil, place the plant so that the crown of the root, shall be one foot below the surface; then at intervals of three or four months fill in two or three inches, by breaking down the sides of the holes.

There is no doubt that by keeping the soil in a good mechanical condition, applying small quantities of manure, from time to time, and frequent watering in dry weather, the trees may be brought into flower in five years, but this is a costly style of cultivation, better suited to the village owner of an acre or two, who performs all the operations by the labour of his own family, than to a large concern, where every stroke of work, has to be paid for in hard cash, and the cost of watering is prohibitive. Among all our large coconut proprietors, there is only one, who combined the command of a perennial river, and sufficient capital, with pluck and intelligence enough, to carry out an irrigation work, that supplies unfeeling moisture to 700 acres of land. But after all, water is only one requisite of high cultivation, and will only yield its best results, in combination with the other necessary works and appliances.

On light deep soil, with proper cultivation, an average of 100 nuts per tree is by no means an outside estimate. There are alluvial flats that yield twice that amount, and large extents of level loamy sands, that seldom average less; and even on less favoured spots, high cultivation will bring the average, well on towards that number. If we cannot estimate the yield of all the mature trees in Ceylon at a higher average than 20 nuts per annum the result is due to the want of cultivation.† There are means open to scientific industry, by which any tree that bears 20 nuts may be made to bear 100. These means are stated by our author thus:—"A well kept plantation should be manured once a year. * * * The soil should be freely ploughed up, and kept loose and broken." To these two heroic

* Our inclination is to believe in a number not nearly approaching 30 to 40 millions of trees in all stages.—ED. T. A.

† And over-crowding in native gardens.—ED. T. A.

operations, he adds irrigation once or twice a week, which being impracticable on most of our Ceylon fields, don't suit us.

Many minor errors may be forgiven to an author who takes such high ground, on the most important operations to the coconut planter. "Keep your soil well broken, and keep putting manure into it," has been for years the oft-repeated advice of one Ceylon planter; perhaps a voice from afar may have more power for furthering the improved method.

We have only two species of beetle that attacks the coconut tree in Ceylon. The *kuruminiya*, a large black one (not figured in this book), breeds in dung-heaps and in accumulations of decaying vegetable matter. It cuts into the cabbage and feeds on the tender undeveloped leaves, the effects of which are not and ragged leaves in after life. It does not breed in the tree but merely dines and departs. Few trees in a plantation entirely escape, and some that are much to their taste, are kept in a chronic state of disreputable ragginess. The other is the red beetle, *kandapanuwa* (eating worm) of the Sinhalese. The dangerous time with this foe, is from the time, the stem shows above ground, till it begins to flower. It has a strong frontal horn, with which it can enlarge to its purpose any crack or wound on the stem, but it cannot penetrate the ripe rind. The rapid expansion of the stem in a quick-growing tree often splits the base of a leaf; and in the crack so produced the young grub lives on the substance of the leaf till strong enough to gnaw its way into the stem. Split leaves should therefore be carefully removed as soon as noticed; but all whole ones should be allowed to remain on the stem till they rot, the danger of removing them being breaking the surface of the stem or exposing it before it is sufficiently hardened. When the grub is detected in a tree, the safest way of dealing with it is to root it out, cut it into chips and collect and destroy the insects in all their stages. Fortunately the whole colony stick to one tree, as long as it stands, and the whole family, sometimes amounting to 150, can be disposed of at once. The grand precaution is never to trim the leaves within three feet of the stem; nine-tenths of the trees destroyed by this insect, on Ceylon plantations, have been due to wounds inflicted on the stems in trimming off dead leaves.

Notes.—18 feet is the length of the leaf of a mature thriving tree.

The manorial elements most needed, is coconut, as in most other cultivations, are nitrates and phosphates in few cases need any others be specially provided, as they are in combination in all manures.

I think a basket of dung more scientific treatment for a coconut tree than a pounding with a paddy pestle.

In Ceylon the coconuts are gathered six times in the year; the Jan.-Feb. crop being the smallest, and June-July the largest.

Two plants from one nut is not an uncommon event, and three are sometimes to be seen, but a single nut here has thrown out no less than five. About 20 years ago a nursery plant was shown at an Agri-Horticultural exhibition in Colombo, with flower on it.

In parts of our lowcountry, where more than 100 inches of rain falls, in the year, the trees carry fine full heads of leaves, but bear comparatively small crops, so that too much molature is rather worse than too much drought. I suppose, that in a saturated soil, the soluble plant food is too much diluted for fruit forming.

THE MODERN PLANTER.

In an article under this head a writer in the *Globe* says:—"The word still calls to the mind's eye a very sun-burned gentleman in a white jean suit, with a Panama hat on his head, a whip in his hand, strong language on his lip, and a combative assortment of cold drinks and fiery seasoning under his waistcoat; a man who is Tory to the backbone in his upholding of old notions and manners and customs, violent in his prejudices, prodigal in his expenditure and lavish

in his hospitality and the limit of whose ideas is defined by the boundaries of his own island. But this accepted portrait is so more true to life than are the stage sailor, or the stage countryman; or the mother-in-law in fiction, or the hero of the penny dreadful, for, although many an East or West India planter leads as solitary a life as did his predecessors in the pre-steam age, he has moved with the times in every respect. But for his snob and his easy costume he might be anything or anywhere but what or where he is. He is not even bronzed by the sun—not half so bronzed as his globe-trotting visitor, or as many a young Englishman after a cricket season or a summer on the river, for the very sufficient reason that when he does go out into the sun, which is only at certain times of the day, he protects himself with broad hat, dark spectacles, and umbrellas. He is usually temperate and as often as not an abstainer, although, for his own good in such a climate, rarely a teetotaler, and would as soon think of laying his whip across the back of a negro as of sitting down to a steady consumption of heavy viands washed down by draughts of heady, fiery liquors at the end of a day's work according to the traditional "good old" custom although he follows tradition in asking his visitor what he will take to drink. Solitary his life often is, he is amidst the tea lands of Assam or the cane pieces and cocoa plantations of the West Indies. He may have to ride twenty-five miles for a doctor and to depend upon the transport on the heads of negroes for the necessities and luxuries of life. His society is simply that of neighboring planters which may mean that from week's end to week's end he never sees a white face. But he is by no means a solitary man, for not only does he surround himself with as many refinements as possible, not only does every mail keep him in constant touch with the Old Country, but as often as not he simply lives on his estate during the 'crop months,' and spends the remainder of the year at home, and is therefore a very distinct and different being from the planter of Tom Oringle's era, who made his estate his world, and regarded a return to the land of his birth as the remotest of contingencies."

The writer might have added that those planters who "spend the remainder of the year at home" are few and far between, and may be regarded as the favourites of fortune. The proprietor of a very prosperous tea or sugar estate may indulge in this form of luxury, but on the majority of tea gardens and sugar estates the resident manager is a hard working man, very much on the spot, and his holidays are not by any means at brief intervals.

Old times are indeed gone. The pay is not what it was, the nature of the work is changed, the responsibility is greater, and, if the planter is not also proprietor, he has to keep a sharp look out on his estimates and his year's working, or he will be speedily called to account. The romance of a planter's life—if there ever were much—is now reduced to a matter-of-fact existence, tempered by tennis, the latest and most economic machinery, and the Mincing Lane markets.—*H. and C. Mail.*

THE MACARONI OF COMMERCE.

Macaroni and the kindred preparations have come to rank among the important food products. This article consisted originally of bits of paste and cheese pressed or squeezed into balls. The name is now applied to a paste which is manufactured from the "semoule" of wheat or wheat meal. It covers many of the Italian pastes which are used for food in one shape or another, but to Americans the form best known and most commonly found on the table is that of wheaten pipes varying from a quarter of an inch to an inch diameter. Spaghetti and vermicelli are classed under the same general head, as are also the infinite variety of tiny fanciful forms which have become such an adjunct in the preparation of soups.

Italy produces the bulk of the macaroni of commerce. Constituting as it does a staple article of diet in that country, its manufacture, indeed is said to be as much a part of the household duties of many Italians as is bread-making in our own country. Naturally the domestic product is made by hand, but in many of the large factories the work is done almost wholly by steam power, though in others hand power alone is employed. The production of macaroni in the household does not require many or complicated appliances. They consist simply of a smooth board, a piece of marble for kneading and a common rolligpin. A mixture is first formed of wheat meal or flour and eggs, the proportion being one pound of the former to four or five of the latter. This is dampened with hot water, then kneaded for several minutes, and at last is rolled into very thin sheets with the pin. These sheets are left some fifteen or twenty minutes on the board to dry, and as soon as it is found that the surface of the sheets is no longer adhesive they are rolled up as tight as possible. Slices are next cut off the ends, and as they separate they form strings of macaroni and are in shape to be used. This is the primitive method. In the ordinary commercial process the meal is merely mixed with hot water, and the dough is forced through molds or dies which give it its familiar form.

The small factories found in nearly every part of Italy, which are operated entirely by hands number in the thousands. In many instances the factory consists of a single room (this does not include the drying-rooms), which serves for a salesroom as well. The labor is performed by the owner of the establishment, with the assistance of one or two men, his wife acting in the capacity of saleswoman. If the expense entailed in running such a factory were considerable the proprietor could not compete successfully with larger and more perfectly equipped concerns. As it is, the price of this machinery is light, the cost for labor small, varying from 30c. to 60c. per diem, while the expense of drying is a mere nothing. In most cases artificial heat is rarely used, but in instances where it is employed the macaroni manufacturer is also a baker, and is able to utilize the waste heat by improvising drying-rooms over the ovens. It is stated, on good authority, that in the majority of these hand-power factories "extreme neatness is observed in every part of the operation where a good quality of macaroni is made." It is estimated that the average production per day per man is from 175 to 200 pounds, and the cost of labor per pound does not exceed one third of a cent, and is often less than one-quarter of a cent.

The latest and largest macaroni manufactories are studiously fitted up with the most modern and perfect machinery obtainable, and run by steam. The largest one in Rome, and presumably in all Italy, boasts a large American engine. This establishment manufactures not only the meal for macaroni, but flour likewise, and it is that ability to so fully provide not only for his own use, but the general market as well, that makes it possible for the steam manufacturer to cope with the hand manufacturer, whose plant has cost him almost nothing, and whose outlay in labor, cost of material, etc., is the merest bagatelle.

In the preparation of macaroni the wheat most generally employed, and considered on the whole the most desirable for the purpose, is either the Italian, which is preferred, the Russian or Indian. Each of these contains both hard and soft varieties, the former being necessary in the manufacture of "semolina," of which four grades are made, and the latter in the production of flour. One authority says that of the wheat mentioned the Italian species

"grown in Apulia is the hardest and strongest, and therefore the best for macaroni. Foreign wheat is never bought for this purpose if Italian can be had. The Indian wheat, though displaying a fair color, is apt to be weak. Good macaroni cannot be made from soft or tender wheat." In a recent series of consular reports on the subject there is but one mention of the use of American wheat. That is in a postscript appended to the report of James Fletcher, consul at Genoa, which states specifically: "R. Ravano, of Quinto, a village about five miles from Genoa, has just informed me that he uses American wheat extensively in the manufacture of macaroni for home consumption." This suggests scope for further foreign trade engagements. It is pleasing to note in the same connection that more or less machinery used in the largest and most successful macaroni factories in Italy bears the imprint of American makers.

The transformation of meal into macaroni in the steam-working establishments is simply an elaboration of the hand process, doing away with much of its laboriousness and admitting many amplifications and improvements. In some districts it is steadily maintained, however, that the quality of the hand-made article has yet to be won by the machine product.

It has not been possible to ascertain the exact amount of macaroni exported, or, in fact, the quantity consumed at home. The reason assigned for this is that, in the first case, captains of vessels leaving for the United States and other countries take on board considerable quantities of macaroni ostensibly and declaredly for their own use, but shipped really to help supply the foreign market. In the case of home consumption, again, the article is so largely provided in the family, especially of the middle and peasant classes, that accurate estimates cannot well be obtained. In 1890 the recorded exports from Italy to the United States and Canada amounted to 137.6 tons out of a total exportation of 673 tons. Of the product of France probably one fourth is exported, and one-third of this amount is sent to the United States. More or less macaroni is manufactured here, but the amount is trivial in comparison with that imported.—Bradstreet's.

AGRICULTURAL ENGINEERING.

A correspondent, an expert in agricultural engineering, writes as follows:—"Dr. Voelcker, though one of our most eminent agricultural chemists, has not resided long enough in India to be an infallible authority on practical agriculture. One of his objections to deep ploughing is that the English form of plough would compress the furrow, and the hot sun would bake it to the hardness of bricks. So it would, if the cultivator used it when the land was wet and sodden, with no immediate prospect of more rain, and so would the native plough; but in no part of India would cultivators be found so inexperienced as to do that. Moreover the mould board plough of the present day does not compress the land into a compact furrow, like the English mould-boards of twenty years ago; they are now made short so as to break the furrow as it is rolled over; any one who has used the American 'Hiodostau' plough will bear me out in what I say. There can be no question of the superiority of deep ploughing over shallow in India;* it is borne out by both theory and practice, and all intelligent native cultivators are aware of this; but the trouble with most of them is, that they cannot afford to pay for large plough bullocks suitable for deeper cultivation.—Pioneer, June 2nd.

* Meaning by "deep ploughing" 6 inches, or 8 at the utmost, instead of about 4.—Ed. T. A.

PROFESSOR MIDDLETON ON ANCIENT GEMS.*

"Gems," in common speech, means a precious stone, especially when engraved for an ornament or other purpose. This, putting aside its primary meaning of a "bud," is pretty nearly its significance in classical Latin, though in both languages it might be loosely extended to comprise a pearl. As used by Professor Middleton in this admirable manual, it has of necessity a somewhat wider significance, taking in certain materials other than the many varieties of precious stones. It includes for instance, Egyptian scarabs, which are often made out of clay or steatite (a variety of talc), Hittite "gems," for which limestone and marble, among other materials, were used, Ptolemaean scarabs, and the metal signets found in the Mycenaean tombs. These are curious and interesting, and some exhibit delicate workmanship and, occasionally, great artistic skill. Still, the most attractive part of Professor Middleton's subject is that which is concerned with the gem proper, and that as it was handled by Greek or Roman artists. Precious stones have always been the most fascinating of human possessions. Their intrinsic beauty goes for something; their durability for more. The imagination is fired when we know that the article one touches is exactly the same as it presented itself to human eyes and hands thousands of years ago; and the feeling is intensified when art has added to the precious material, in the design, the name of the owner, or it may be of the engraver, a distinct human interest.

When we talk of precious stones, however, it must be remembered that the minerals of which the vast majority of the finest antique engraved gems are made are by no means rare or costly. The diamond, for instance, though it occurs in ancient art, occurs only in its natural crystal, the art of working it not having been discovered till comparatively recent times. (The "diamond" of the High Priest's breast-plate was possibly a white sapphire. The minerals used belong in the main to a single species known as quartz, and consisting of silica, the oxide of a non-metallic element called silicon. Of these silicious stones there are numberless varieties, differing from one another in texture and colour, and through the presence in small quantities of accessory or intruding materials. Colourless rock crystal is the fundamental type of the species. Amethyst differs from it only in its colour, which is generally violet, but sometimes citrine, and its curious piquetted structure. Among the translucent varieties of quartz are the sard, of which Professor Middleton remarks that "it is the most beautiful material commonly used for ancient engraved gems," a stone amber-coloured, red, or reddish-brown; the less translucent cornelian (Professor Middleton always calls it carnelian, erroneously, we cannot but think), chalcedony, which is milky or bluish, the apple-green chrysopease, and the leaf-green plasma. Jasper, of which there are many varieties, and which is of very common occurrence, is almost opaque. Another very common stone is the onyx, which is made up of two or more bands of strata, varying in translucency and hue; when one of these strata consists of sard, it is called a sardonyx. That sardonyx is peculiarly interesting from its frequent mention in classical writers. Plato speaks of it, though, as Professor Middleton tells us, it does not often occur in Greek gems. The Romans used it largely, following the fashion set by the elder Scipio Africanus. Among non-silicious

stones are the chrysoberyl, the topaz, the emerald, the almandine and other garnets, the peridot, the turquoise, the opal, and the lapis lazuli (the *sappirus* of Pliny the elder),—and these, from the peridot onwards, are softer than quartz, or even than ancient paste or glass. It must be remembered that, for artistic purposes, the most transparent substances, whatever their intrinsic charms, are not necessarily the most beautiful. It is the translucent stones, such as sard and chalcedony, that are more suitable. Through these, light, but not the forms of objects, can be discerned, and so they reveal the charms of fine and noble workmanship more than do the perfectly clear beryl and rock-crystal. In the former, the light passes less regularly—that is, with more scattering of the rays—than in the case with transparent stones, and thus the design seems to be illuminated from within. On the other hand, the opaque substances are less suitable for the purpose. Even such stones as the heliotrope and the turquoise, which are capable, when in thin splinters, of transmitting a little light, produce an effect other and more pleasing than do the perfectly opaque materials. Some of the incident light plunges a little way below the surface of the gem, and lights up its superficial layer.

Precious stones, like all other things of value, have been imitated. So we find that many "gems," as it will be still convenient to call them, have been wrought or reproduced in paste and glass. Paste was a hard glass coloured by various metallic oxides, such as those of manganese, iron, copper, and cobalt. Sometimes a piece of paste was treated by the gem-engraver just as if it were a natural stone, and sculptured by the aid of the same tools; but more generally the glass was melted and pressed into a mould. Such a mould had been taken from an engraved gem by a pellet of clay which was afterwards hardened by fire. Paste-gems are often of great beauty in colour and design, though the material lacks some thing of the optical properties which distinguish not a few of the true natural stones.

The tools and processes employed in ancient times in engraving gems are virtually the same as those in use today. The tools were five in number. The drill worked by a bow was the chief. It varied in size, was made of bronze, and acted in virtue of the emery or corundum powder (mixed with oil) with which its point was smeared. The drill was occasionally tubular; in that case its crown was sometimes set with small crystals of corundum. The second tool was a wire-saw, made effective with the same abrading material. The wheel, or disc of bronze, was similarly employed. A file was also used, not of metal, but of a mixture of emery and resin, heated together, and then allowed to solidify by cooling. The fifth tool was a graver, made by mounting in an iron or bronze handle a crystal or crystalline fragment of diamond or of sapphire, or sometimes a piece of rock-crystal. As a rule, in engraving antique gems, and also those of the cinque-cento time, the tool used was worked by the hand, the stone to be engraved being fixed. In more recent days, the reverse arrangement is followed, and in consequence the touch is less free and the style more mechanical. The engraved work and the field of gems were polished by rubbing them with fine powders, hematite, or red oxide of iron, having been generally employed for this purpose.

Paste was often legitimately used, but it naturally suggests the subject of fraud. The ancients were not inexpert in this branch of art, if it may be so called. One might say that the pair of green glass pillars in the temple of the Tyrian Hercules

*The Engraved Gems of Classical Times. By J. H. M. Middleton. Cambridge: The University Press-1891.

which the priests declared to Herodotus to be emerald, were a gigantic imposture; but it is not unlikely that the historian deceived himself. Of jewellers' frauds, the chief was the making of a "doublet," a paste backed with a real stone of greater hardness, but poor colour. The two materials were joined by an invisible cement, the line of junction at the girdle of the gem being concealed by the mounting. The alteration and accentuation of the colour of natural stones, particularly of the onyx, by means of various chemicals, is a comparatively recent invention; but the ancients were adepts in the art of changing the original hues by means of strong heat.

Professor Middleton devotes much space to another class of fraud, the modern imitations of ancient gems, imitations sometimes so clever that they puzzle even the expert. Again and again we find mention of specimens which it is necessary to leave doubtful. One curious sub-variety of this subject relates to the fraudulent signatures. It is obvious that a signed gem has a special interest. Hence many gems really ancient have had false signatures added to them. Here, again, experts are sometimes at a loss. The famous Carlisle "Mercury" is quoted as a case in point. It bears the name of Dioskorides, and, whether ancient or modern, it is a fine work of art. Unhappily, it once belonged to Baron Stosch, who was in the matter of gems much the same as the notorious Samnides was in the matter of manuscripts.

Professor Middleton completes a singularly interesting book by a descriptive catalogue of the engraved gems in the Fitzwilliam Museum, illustrated by two plates giving autotype reproductions of some of the principal Roman gems.—*Spectator*.

THE SPREAD OF COTTON CULTIVATION IN INDIA, EGYPT, CEYLON, AFRICA, &c.

It is a very significant fact that, in spite of the gloomy prognostications shadowed forth in cotton circulars and the pessimistic views enunciated by spinners all over the world, the spread of cotton cultivation continues. The enormous American crop this year, which is expected to touch close upon 9 million bales, is held accountable for the stagnation in prices; but a theory has been advanced that the large outturn will have so exhausted the soil that the crop next year will be a very small one. How far this idea will prove true time alone can show, though most people, we suspect, will not put much faith in it. It is not so very many years ago that an American crop of one million bales was considered abnormal, whereas now it has increased seven, eight and nine fold. The same rapid advance in outturn is apparent in Egyptian and East Indian cotton, and yet the supply is yearly taken up, and the cry for more continues. Quality has certainly fallen off, to some extent, to make up for quantity, and this may be regarded much more as the true reason of the decline in prices than excessive production.* This hypothesis seems to be borne out by the efforts made to discover fresh fields for cotton cultivation and by the attempts to improve the outturn on existing cotton land. The development of the Egyptian cotton trade is progressing apace and in spite of the opposition offered by the French the opening up of the country by railways is proceeding rapidly. An arrangement has been entered into between the Suez Canal Company and the Egyptian Government for the construction of a light narrow

gauge railway from Ismailia to Port Said to be worked exclusively by the former; and the question of settling the construction of a line between Port Said and the Damietta branch of the Nile is under discussion, and will no doubt be rapidly pushed through. As such a line would tap one of the principal cotton centres it is only reasonable to suppose that a stimulus will be given to the trade and that this will result in an increased area being cultivated.

More ground is being planted with cotton in India year by year; and that the business should continue to flourish in spite of the serious charges of adulteration proved against the sellers, is sufficient evidence that, thus far at least, it has not been overdone. Ceylon has of late years been endeavouring to grow cotton, but until Captain Gwatkin, a planter, took to its cultivation and preparation in a careful manner the experiment did not meet with much success. His original idea in planting cotton bushes was that they should act as a shelter for cocoa plants, but it is expected that he will, in common with other planters, now go in for the cultivation more for its own sake. Most of his cotton was grown from New Orleans seed, and about 200 acres were sown with it. It was sown in September last, and picked in February. This yield was not very large, being only about 85 lb. of seed cotton per acre, or say about 30 lb. of cleaned cotton; but as a second picking, and even possibly a third is expected the outturn will compare very favourably with the average yield in India. The cotton was cleaned by steam, in Macarty's gins, which Captain Gwatkin obtained for the purpose and personally supervised. The seed is readily bought in the District at Rs. 3 per cwt, and the whole of the cotton was taken eagerly by the Colombo Spinning Mills. It is said to be beautifully white and free from stain, with a long and silky staple. As it grows rapidly and gives a quick return, a ready market being always obtainable, the industry of cotton growing in Ceylon, especially as it can be grown as a subsidiary and "shade" crop, is likely to make rapid progress. But the extension the cotton cultivation is by no means confined to India, Egypt and Ceylon. One of the principal sources of revenue that the British East Africa Company counts upon is cotton. The country is said in parts to be eminently adapted to its cultivation, and an indigenous wild variety already exists in considerable quantities. It is estimated that by the introduction of imported seed, for which the conditions are favourable, a valuable and superior kind of cotton can be produced. Land and labour are cheap and plentiful and the difficulty in the matter of transport will speedily be rectified. Turkey and Greece are also both extending their cotton cultivation, and half the cotton used by the local mills in the latter country is locally produced. The glowing reports lately published as to the suitability of the soil in Central Asia are also bearing fruit, and Russia is determined to make the most of her occupation of that country. M. Gougon, a Russian of high official position, went to America last year and, with the approval of the Czar, bought a cotton plantation in Louisiana, in order to make a practical study of cotton growing. Having mastered the business in all its details he has now gone to Central Asia to inaugurate the cultivation of cotton there on the most approved principles. He asserts that the choicest qualities can be grown at prices which will drive American cotton out of the markets of Europe! How far he has permitted his enthusiasm to outweigh his experience a few years will show. There is, however, no doubt that if equally good cotton can be grown in Central Asia a very severe

* The adulteration of Indian cotton with dirt and by the mixture of inferior with superior kinds has greatly discredited the product.—*Ed. T. A.*

blow will be dealt to the industry now held almost as a monopoly by the United States.*

There are several descriptions of cotton in every cotton growing country known as "grades," which is an accurate term since the cotton is botanically the same, only produced on different soils and under different conditions. There are supposed to be five distinct botanical species, but for practical purposes cotton may be divided into two great divisions, viz. cotton of the East, and cotton of the West, or cotton of the Old and New Worlds. The former is distinctly inferior to the latter, and in addition to its indigenous superiority has had the advantage of scientific cultivation. The finest description of cotton grown is a superior grade of Egyptian, and next to it comes the famous Sea Island. This is supposed to be a native of Honduras, whence it spread to the West Indies and was thence transferred, about 100 years ago, to the United States. It requires a mild, soft, maritime climate, and before the present century the principal supply was obtained from the West Indies, and the finest probably ever grown was raised on the Island of Tobago. It was for a long time supposed that Sea Island cotton, hence the name, could not be grown on the mainland; and it was not till Florida was ceded to the United States that it was discovered that it could be grown there to perfection. It is, however, a curious fact that "in-breeding," or using the seed from the same locality time after time, has a most deteriorating effect on the quality. It is now believed that the finest descriptions of cotton, including Sea Island, can be grown in the Argentine Republic and on the banks of the River Plate, and experimental cultivation is shortly to be attempted. If the supposition prove correct, a large increase will be added to the already enormous crop of American descriptions, which is also likely to be augmented by certain improved methods of cultivation and selection of seed in existing cotton States.

We thus see that Egypt, America, and India are all yearly endeavouring to increase their output, whilst East Africa, Central Asia, and Ceylon are all in a fair way to assist in the production of cotton. So long as the demand for cotton continues, and new spinning mills continue to find work, so long may we expect to find a corresponding stimulus given to cotton cultivation, and it is idle, in the face of such facts as we have given, to attribute the falling off in trade to over production. As soon as it ceases to pay to produce cotton its production will receive a check; but even at the present low range of prices there is, so far, no evidence of the industry having been found a losing speculation. It will be well, however, for producers to bear in mind that with so many markets for buyers to choose from it is of the first importance that the greatest attention be paid to quality. Hitherto the supply and demand have scarcely been balanced, and any kind of cotton has in consequence been accepted, and worked up in the best manner possible. Quite the reverse, however, will be the case when buyers begin to pick and choose.—*Madras Mail*, May 26th.

CAOUTCHOUC can be dissolved more readily (according to *Pharm. Centralh.*) by adding from 5 to 15 per cent. of oil eucalyptus to the bonzol or carbon bisulphide used; in the latter proportions, the mixture of carbon bisulphide will dissolve nearly 20 per cent. of caoutchouc.—*Indiarubber Journal*.

* In Central Asia the real question will be that of plentiful, steady and cheap labour, in which the Northern American States are so exceptionally favoured.—*Ed. T. A.*

FORESTS AND RAINFALL.

The following letter from a well known hand appears in the *Madras Mail*:—

SIR,—Since last addressing you on this important subject my attention has been called to a work which should be carefully perused by all Civilian and Native statesmen—"Man and Nature," by George Marsh, (Messrs. Sampson Low & Co., London, 1864)—and I trust you will allow me to quote the following passage which so decisively confirms what I have previously pointed out on the effects of woods in causing rain to fall in moderate showers distributed over a considerable number of days; whereas, in the absence of woods, the tendency of rain is to fall in destructive torrents which afford to agriculture a comparatively small amount of benefit accompanied with a large amount of damage. Mr. Marsh, I may observe, is an extremely cautious writer, for after giving many instances to prove that in tropical countries especially, forests increase rainfall, he thus sums up at p. 196:—

"The effects of forests on precipitation is not entirely free from doubt, and we cannot positively affirm that the total quantity of rain is diminished or increased by the destruction of the woods, though the theoretical considerations and the balance of testimony strongly favour the opinion that more rain falls in wooded than in open countries. The important conclusion, at least, upon the meteorological influence of forests is certain and undisputed: the proposition, namely, that within their own limits, and near their own borders, they maintain a more uniform humidity in the atmosphere than is observed in cleared grounds. Scarcely less can it be questioned that they promote the frequency of showers, and that, if they do not augment the amount of precipitation, they equalise its distribution through the different seasons." Woods also, he tells us, influence the dewfall, another most important point, and on this Mr. Marsh quotes Schacht (*Les Arbres* p. 412) who remarks on the effect of forest in increasing the deposition of dew in the neighbouring fields. He also says that it attracts rain from the clouds, and observes that "forests, in a word, exert in the interior of continents, an influence like that of the sea on the climate of islands and of coasts; both water the soil, and thereby insure its fertility." With reference to what Schacht writes as to woods attracting rain from the clouds, I may mention that Mr. Jamieson (Superintendent of Oinohona Gardens) informs me that he has often found the trees in the sholas dripping where the land outside of them was quite dry.

At page 201 Mr. Marsh remarks on the great importance of forests in economising the water in rivers, and this effect here is most marked, and many clear proofs are given in corroboration. In fact, the effect of forests is like the effect of undrained moorlands at the sources of streams. The forests and the undrained moors part with their moisture slowly, and afford an even and moderate supply of water for a long period. But cut down one and drain the other, and you have the same quantity of water perhaps, but rapidly running away in destructive floods. In such floods in the tropics how much valuable water must run to waste, and, almost worse still, silt up tanks and other irrigation works. I have pointed out that forests increase the humidity of the air, and it may be well to quote Marsh (p. 177) who says that "trees increase the humidity of the air by pouring out into the atmosphere in a vaporous form the water they draw up through their roots, and the last operation at the same time lowers the temperature of the air in contact with or proximity to the wood, by the same law as in other cases of the conversion of water into vapour." In short a wood is an irrigation work for moistening the atmosphere and increasing the dewfall, and whether it increases the total rainfall or not, it practically increases it for the agriculturist by causing the rain to fall in a better way, and to be distributed over a great number of days and lastly, but by no means least, woods economise the rain after it has fallen. It is clear then that woods can enormously increase the available water supply in India, and as they can also greatly increase the available manure by doing away with the necessity

for using cattle dung for fuel, it is evident that of all measures for the benefit of the people the planting of woods in the dry interior regions of the continent is a work of the most urgent importance.

ROBERT H. ELLIOT.

Oetacamund, May 31st.

We have written frequently and copiously on the subject discussed in Mr. Robert Elliot's letter, given above, and we see no reason to alter or modify our long-formed opinions. The present season has afforded additional proof that denudation of forest and its replacement by cultivated plants in the mountain and rainy region of Ceylon (in the track of the monsoons) have not lessened the average rainfall over such region the thousandth part of an inch. The culture of the ground, too, enabling it to absorb much of the moisture which falls, has largely prevented floods, which, however, occurred at intervals in a very formidable fashion, when the forest stood unviolated by the woodman's axe. The forest existed in luxuriance on the mountains and plains of the south-west portion of Ceylon, because the region was rainy. In the dry and arid parts of the country forest was and is either absent, or stunted and peculiar, according to quality of soil and contiguity to rivers, streams, canals or tanks. We doubt if the afforestation of such dry and arid regions, however desirable it may be,—and most desirable it is,—will increase the actual rainfall by a decimal of an inch. But apart from their value, otherwise, forests conserve such moisture as may be deposited or may exist, and so they modify temperature and the conditions of climate generally. Let forests be judiciously conserved and judiciously extended, by all means, therefore; but let there be no extravagant expectation that the great dynamical laws of nature can be revolutionized by man's puny efforts. Forest is plentiful because rain is plentiful, but the converse of the proposition is not true. Plentiful rain will not follow abundant forest. Over a large portion of Ceylon and much larger portions of India, natural forest is scarce or absent, because of the paucity of rain. To produce forest artificially in such regions is difficult but not impossible. Success will secure many beneficial consequences: amongst the rest economy of moisture by reducing floods and evaporation. But we are utterly sceptical as to any appreciable increase of the deposit of rain from the atmosphere, by any process of afforestation which can be carried out.

INDIAN TEA IN PARIS.—Mr. Thomas Lough* tells me, says the correspondent of a contemporary, that the experiment of opening a tea pavilion in Paris has succeeded beyond all his anticipations. Two more establishments are about to be started by the same enterprising company, one in the Champs Elysees, midway between the Palais de l' Industrie and the Arc de Triomphe, and the other on the Boulevard Bonnes-Nouvelles, the centre of the theatre quarter. It is gratifying to find that the fastidious Parisians are taking so kindly to Indian tea. Did I ever tell you about a curious remark made to me by a Frenchman in Paris a few months ago? We were talking about the growth of tea drinking in the gay capital. My friend observed, "Oh yes, I drink tea and like it, but I am not like you English, I don't drink it with my dinner!" This gentleman was the leading official in a wellknown banking house, near the Place de l'Opera, and prided himself on his knowledge of our ways.—*Madras Times.*

* Whose proceeding do not find favour in Ceylon.—*Ed. T. A.*

THE GOVERNMENT COFFEE CROP this year for Java is estimated at pikols 351,268.—*Singapore Free Press.*
TANNIN WRITING INK.—Dissolve 15 drams tannin in 17 ozs. water (*Ch. & Dr.*), add a mixture of 1 oz. 10 per cent. solution of perchloride of iron, 12 drops sulphuric acid, and 12½ ozs. water, dissolve in this mixture 5 drams of deep black dye.—*E.—Pharmaceutical Era.*

TREATMENT OF INGROWN NAIL.—Dr. Parcklauer (*Therapeutic Gazette, Am. Jour. Med. Science*) moistens the surface of the diseased nail with a luke-warm 40 per cent. solution of caustic potash and then scrapes off the softened upper layer with a sharp-edged piece of glass. After a second application the scraping is continued until the nail is as thin as a sheet of paper. It is then lifted up from the soft parts with forceps and the diseased parts are excised.—*Pharmaceutical Era.*

TEA AT £30 PER POUND.—Of course there is no reason why there should be any limit to the price offered for gold-tip tea if the buyers think that by spending their money that way they get more fun from an advertisement point of view. As mentioned last week by our Commissioner in the Lane, a little box of tea weighing 5 lb. net, and containing silver-leaf flowery Pekoe, from the Kellio Estate in Ceylon, was sold on Thursday at £30 per lb., or equal to about 37s per punnet. The lot was knocked down to Messrs. Hawes & Co., tea brokers, who bought it for Mr. Owen Edwards, dealer, of King William Street.—*H. and C Mail.*

THE MAGAZINE

OF

THE SCHOOL OF AGRICULTURE,

COLOMBO.

Added as a Supplement monthly to the "TROPICAL AGRICULTURIST."

The following pages include the contents of the *Magazine of the School of Agriculture* for July:—

OURSELVES.

THIS number we enter upon our third volume of the Magazine of the School of Agriculture. So far the contributions to the Magazine have been solely from the pens of the staff of teachers at the School and the old boys of the Institution, to whom our thanks are due for their help in the endeavour to fill the Magazine with interesting and varied contents. To judge from the kind notices in our daily contemporaries, to whom also we owe a debt of gratitude for their encouragement, we have not wholly failed in this endeavour. We must however take this opportunity of appealing to all those who have severed their direct connection with the School of Agriculture to make a more determined effort to send us news and notes from the various parts of the Island over which they are scattered: and especially to those who have the advantage of occupations which necessitate travel do we appeal (in the absence of *bona fide* Agricultural Inspectors) for such reports as they can find time to send us in the midst of their other duties. Such reports, coming as they will from those who are capable of careful observation as well as judgment in agricultural matters, while they will, when published, make our publication more interesting, will at the same time keep us alive to the condition of native agriculture—which, owing to various controlling causes, is full of vicissitude—and place us in a position of greater advantage than we are able to attain to any otherwise, inasmuch as we shall thereby have a more extended range of observation to our mental eye, and be better able to deal with matters affecting remote places.

OCCASIONAL NOTES.

Hibiscus Cannabinus, of which mention was made in our last issue as being grown together with cotton in India, is being grown experimentally at the School of Agriculture, where the plants have come up fairly well. It is mentioned in Thwaites' *Enumeratio*, as growing "near Trincomalee." Like *H. Esculentus* (Bandikai) the bark yields a fibre of some value. Wight mentions that the leaves are eaten as spinach. The plant resembles the *H. Subdariffa* or rozello from the fleshy acid calyx, of which excellent jelly is prepared. We are informed that it is grown about Anuradhapura both as a fibre plant and a food-product.

In the School of Agriculture grounds are a few trees of the order Leguminosæ which, according to Dr. Trimen, belong to the genus *Millettia*. The seeds were originally sent to Mr. H. D. Lewis, late Head Master of the School, by a gentleman in America, and was by the latter referred to as "Madro do Cacao." This term is in Ceylon associated with the *Erythrina*s, used as shade for cocoa plantations, and it is to be inferred that the specimens of *Millettia* we have are used for the same purpose elsewhere. These trees are of an uncommon appearance with long supple plume-like branches. Two of them flowered for the first time early this year and displayed an abundance of pretty pink and white blossoms. It has been found that any broken branch or twig stuck into the ground in a moist place grows without difficulty. The specimens at the School are probably the only ones in the Island.

There seems to be a good deal of uncertainty about the identity of the resinous substance known as Dragon's blood. In Cooley's *Cyclopædia*, Dragon's blood (*sanguis draconis*) is described as a rich red resin, obtained from various species of *Calamus*. In a list of economic products of the vegetable kingdom, published by Robert Hard-

wicke, it is given as a red resinous exudation from *Pterocarpus Draeo*, a leguminous tree. The substance would appear to have been valued in times past not only for its medicinal properties, but also for tingeing varnishes, especially the varnish used in violin manufacture. It is we believe generally considered among violin makers that the identity of the real Dragon's blood—to which is due not only the beauty, but also in some measure the richness of tone of old violins,—is now lost, and that what is sold at present as Dragon's blood is a spurious article which, though it closely resembles the original, has not its much-desired qualities. The following is a recipe given by Cooley for making the factitious Dragon's blood:—Shellac 4 lb., melt, remove from the fire, and add Canada balsam 6oz. and gum benzoin 2oz.; mix well, stir in red sanders wood (or sandalwood) 1½ lb.; and Venetian red ¾ lb. (both in fine powder); and form the mass into sticks. In another recipe the Venetian red is omitted.

Resinous exudations from trees of the red or ruby colour of Dragon's blood are not unknown in Ceylon, but they are objected to either because the tint does not quite come up to the standard of that of Dragon's blood, or because they do not, as is necessary, mix with turpentine. The genus *Pterocarpus* includes many trees containing red colouring matter. From *P. Marsupium*, the red sandal or sanders wood is derived the red gum kino, which is used medicinally by the natives.

The *Ceylon Independent* announces the interesting fact that a committee has been formed, with Father Lytton at its head, for taking steps to sink an artesian well in a suitable locality. The sum of R4000 has been fixed as the amount necessary, of which the Roman Catholic Mission proposes to give R1000. The lawyers, who form the bulk of the committee, are expected to contribute a good round sum.

The fibre from the musk plant (*Abelmoschus moschatus*)—Like a great many of the malvaceae, produces a fibre which is said to be as good as any for bag and rope making. The seeds, which possess a heavy and peculiar odour, are used for flavouring purposes, and at one time sold for over a pound sterling per pound weight; but their value has gone down, we are told, owing to the discovery of a chemical substitute possessing the same properties. There are a few of these bushes growing and fruiting freely at the School of Agriculture.

RAIN.

Rain water, though commonly spoken of as pure, is by no means chemically pure water. It always contains a certain amount of oxygen and carbonic acid gas which it takes up in its passage through the atmosphere. In the vicinity of towns it is rendered still more impure by the presence of nitric and sulphuric acids, which increase its disintegrating power on both natural and artificial structures. On reaching the ground rain takes up more carbonic acid gas, and among other things, decaying organic matter: and it is to the presence of these two substances, together with oxygen that its power as a weathering agent

is mainly due. While oxygen alters and breaks up rocks by oxidising their constituents, and while organic matter brings about the same results by deoxidation, the carbonic acid present in rain water forms easily soluble carbonates out of less soluble compounds. While rain water easily washes away the chlorides and nitrates of soda and lime, most soils are able to firmly retain the phosphoric acid, ammonia and potash, which are little if at all found in the drainage water. Even on the heavy soils at Rothamsted, and with a rainfall of only 17 inches, the nitrogen removed every year in the drainage water from bare follow amounts to over 40 lb. per acre, equal to about 2½ cwt. of nitrate of soda. When the roots of a cultivated crop are present to utilize the nitrates as they are formed in the soil, there is of course much less loss. On the other hand, if rain does cause a loss of the valuable constituents already present in the soil, by washing over and soaking through the land, it also imports appreciable quantities of nitrogen in the form of ammonia and nitric acid from the atmosphere into the soil. The rain as it falls in the country in England has been found to contain about 9 parts permillion parts of ammonia, and 19 of nitric acid. Dew and hoarfrost contain, according to Dr. Fream, three or four times the amount of ammonia and nitric acid found in rain water. At Rothamsted the amount of nitrogen as ammonia in rain, mean of 5 years, was found to be 2.4 lb. per acre; nitrogen as nitrates and nitrites about 1 lb.; as organic nitrogen a similar quantity: giving a total of 4.4 lb. per acre. The average of many experiments made on the Continent gives 10.23 lb. of nitrogen per acre brought down by the rain. This high average is to be explained by the fact that many of the determinations were made near towns, where as a result of thick population and its attendant conditions, more ammonia and nitric acid passes into the atmosphere than is the case in country places. Warrington gives it that chlorides are always present in rain; at Cirencester the chlorides in rain water are said to be equal to 40 lb. of common salt per acre per annum. At Rothamsted it was found that 24 lb. of sodium chlorides were supplied annually by rain.

Looking now at the mechanical action of rain, we find that it has a tendency to wash away and carry off the more easily-weathered parts of rocks and soils. It is a common experience to find after a sharp shower of rain, a number of miniature pillars left standing on roads and bare lands, representing either the more durable matter which withstood the mechanical action of the rain, or such substance as, though not of a durable nature, has been protected from the weather by a pebble or piece of rock capping it. This simply though forcibly illustrates what goes on around us on a large scale. The mechanical action of rain water results in the washing away of soil to a large extent from hill sides, where the transporting power of water is increased by the gradient of the land. Where the rainfall is crowded into limited periods this effect is of course greater than in places where the same rainfall is evenly distributed throughout the year. But what is lost to the cultivator of the hill slopes is generally gain to the tiller of the plains below; transportation of soil from one place resulting in accumulation in another. Another result of the rainfall of a district

being crowded into a short and heavy rainy season, is that the rivers gain in erosive and transporting power, owing mainly to the increase in their volume, which may go on to such an extent that the lower reaches of the river become flooded. These periodic floods due to continuous heavy rains cause much damage to cultivators by submerging their crops, though there is the advantage of a deposit of silt to be expected when the waters abate, which adds appreciably to the fertility of the land.

The "washing out" of soils on hilly land can of course be mitigated to a very great extent by an intelligent system of drainage, but those landowners who are unfortunate enough to cultivate within the inundation area of rivers, can do little to minimise the evil-effects of long-standing water on their crops. In these latter cases where generally proper outlets for flood water are what are only necessary to avert the evil results of inundations, it is manifestly the duty of the Government to see to the alteration of those natural conditions which prevent the flowing off of this water.

There are, besides, other considerations than the fostering of the agricultural industry—for instance, the danger to health from stagnating water and decomposing vegetation—that should weigh with the Government in undertaking the necessary measures, so far as they are practicable, to prevent if not the recurrence, at least the continuance of floods when they do occur.

THE MADU TREE.

(*Cycas Circinalis*.)

By W. A. DE SILVA.

The Madu tree or the Ceylon Cycad grows commonly in uncultivated places. It has the appearance of a palm, and belongs to the Taxid family. This tree abounds in the jungles of Dumbura, Kadugannawa and other districts.

The Madu has a branchless stem, but occasionally branched exceptions are met with. Twelve to sixteen leaves spring up at a time from the top of the tree. When the first set of leaves mature, others come up in the same manner to replace them.

The Cycas is a dioecious tree. The staminate and pistillate flowers being borne on different plants. When the flowers come up they emit a peculiar nauseous smell.

It is seen in fruit in November and December, and the fruits resemble large arecanuts. The ripe fruits are sometimes chopped into pieces and dried, and a flour is obtained by pounding them, after removing the outer shell and soaking in water. This flour resembles somewhat that of rice, but has a peculiar smell though not of unpleasant taste. Sweetmeat and other preparations are made from Madu flour, which is generally much used on account of certain medicinal properties it possesses, especially in alleviating rheumatic pains. Dried Madu fruits are often sold in the village bazaars at from six to eight cents per measure, about hundred and fifty fruits going to form a measure.

The tender Madu leaves are covered with a glossy epidermis, and after this is removed they are generally made into curries for use as food.

NOTES FROM A TRAVELLER'S DIARY.

While travelling through Walapane in March last, and passing through some of the villages in the interior, I was struck by the novel appearance they presented, owing to many of the dwellings having sunflower plants, gay with golden blossoms, growing around them. On enquiry I learnt that these plants had been raised by some of the boys attending the Government School in the neighbourhood. The teacher of this institution had himself got up a pretty little garden of sunflower trees opposite the school-house; and it was he who had distributed the seed among his pupils, giving them instructions how to grow them, and explaining to them the economic value of the trees.

Insignificant as this bit of experience on my part may appear to be, it goes to show that there is a deal of good work to be done in introducing plants and trees from one part of the Island to the other, as well as totally new products that may be found suitable. Dhall, arrowroot, breadfruit and various kinds of yams can with advantage be introduced into these parts. It is just here that one sees the great need there is for Agricultural Inspectors, who while itinerating will ascertain the wants of the inhabitants of remote villages, and lead the cultivators into the way of bettering their position.

I paid a casual visit to the garden of a Moorman in Walapane, and found that he had four or five prolific bread-fruit trees planted there. These plants he had brought with him all the way from Dodanduwa in the Southern Province. By means of a Government officer who will supply seeds of jak, bread-fruit, &c., and instruct and advise the cultivator as to the best means of growing them, the inhabitants of these unfortunate parts may be induced to grow such products as have been mentioned, in their chenas. But it is only by personal influence, and the influence of a Government officer, that such results may be hoped to be brought about.

Of planting-products, coffee is still represented in the village of Walapane, the trees looking healthy enough, and giving promise of a good crop. Having been convinced that cocoa would thrive in most of the villages, and getting several of the villagers to promise that they would give it a trial, I intend sending the village schoolmaster in Walapane a supply of cocoa seed for distribution among the schoolboys. The ubiquitous Moorman is always on the look out, even in the remotest villages I have visited, to buy what coffee, cocoa, pepper, &c., he can get from the villagers.

I cannot say that cotton gives promise of being a favourite with the village cultivator. I know of cases where cotton was grown on a small scale and a few pounds of lint taken in, but the main difficulty in these cases was the selling of the lint. The Moorman will not buy it, for good reasons so far as he is concerned, and it is not to be expected that a villager will take (will dare to take) a few pounds of cotton to the Kachcheri for sale.

After what I have seen of cotton cultivation in Ceylon, I do not think it will pay when grown as a separate crop, and I would advise that it should be raised, as is frequently done in India, with some other crop. At the Hunuketale cotton plantation in the Matalo district, the property of the Spinning and Weaving Company, I was disappointed to find that cultivation was to all appearances given up, and that but for a few prominent cotton trees the land was overrun with a jungly growth. The surviving plants I found to be either of the kidney or Egyptian variety.

Last February I passed the Government Relief Garden in Walapane. It will be remembered that this garden was opened to give employment to the unfortunate people of this district who had lost their paddy lands, Tobacco and cotton appear to be the only crops that any attempt was made to grow, and their cultivation cannot be said to have been successful. One would have expected that useful and suitable food products would have been raised in a place like this, instead of such doubtful crops as those that have been tried; and the Relief Gardens bring to mind the Alfred Model Farm that proved a failure owing to mismanagement. After the major part, if not the whole of the money allowed for relief work in Walapane was expended, it seems that the services of an Agricultural Instructor were secured. This officer was expected to cultivate the land with the aid of a few school boys, by no means willing to work, who are expected to turn out for an hour or two a day (holidays excepted). The previous record of the Relief Gardens has by no means left an encouraging effect on the inhabitants. I heard that dhall, arrowroot, betel and yams have been grown, and that arrangements were being made for planting sugarcane, bread-fruit and jak. It is a pity that the Agricultural Instructor could not have begun work under better auspices.

[Mr. H. D. Juanis, the Agricultural Instructor, Walapane, who was unable to obtain leave during illness contracted at Lemesuriergama, whither he had been sent, broke down completely in health, and was obliged to resign his post.—ED.]

TRAVELLER.

THE CASTOR OIL PLANT.

(*Ricinus Communis*.)

BY W. A. DE SILVA.

The Castor Oil plant which flourishes in the warmer parts of the world, is grown largely along with other crops in the different districts of India.

There are two varieties of this plant; one has pink stems and petioles, and generally grows to the height of from six to eight feet, while the other variety is characterized by the pale ashy colour of its surface. The Castor is a quick-growing perennial, with delicate stems filled with soft tissue. The leaves are large and penta-fid with numerous prominent veins, and they are borne on long and smooth petioles. The plant is monoecious, bearing distinct staminate and pistillate flowers upon the same raceme. A large number of capsules are borne in clusters,

and when dry the oval-shaped black and smooth seeds are easily separated. These seeds contain a large percentage of an oily matter which has a peculiar smell and the properties of a purgative. On account of the latter property it is much used in medicine.

The Castor Oil plant thrives in light soils, and is generally cultivated along with other crops, such as beans, varagu and eumbu. The plants begin to produce in their fourth month, and in India much profit is obtained by its cultivation. It grows wild all over the Island of Ceylon in light soils, and the rapidity with which it comes up without any care in the soils of the Cinnamon Gardens is remarkable.

The leaves of the Castor plant form the food of a variety of silk-producing moths.

The oil fetches from 3*d.* to 5*d.* in the London market, whilst the Castor cake or poonae is considered to be a good fertilizer, and is in great demand.

This plant might be usefully added to the garden and chena products of the villagers, who will be able to raise it along with their other crops.

CEREMONIES OBSERVED BY THE KANDYANS IN PADDY CULTIVATION.

It may not be uninteresting to the readers of your useful Magazine to know something about the ceremonies observed by the Kandyans paddy cultivators, and I trust that the information which I have collected and embodied in this paper will not be considered altogether unprofitable reading.

After having selected a suitable plot of land for cultivation, the goiya presents himself before the Neketrala (village astrologer) on a Monday or Wednesday with the customary offering of forty betel leaves and arecanuts, and expresses his wishes in a humble attitude. The Neketrala then informs his petitioner, after certain astrological calculations, the circumstances upon which the success or failure of his undertaking depends. On an auspicious day (according to the Neketrala), the goiya after partaking of heel-bat (the morning meal) wends his way to his land with a mamoty, his face turned towards the favourable direction of the horizon as indicated by the astrologer, should the goiya on this journey encounter sights or sounds which portend failure—*e. g.*, the hooting of an owl, the cry of a house lizard, the growling of a dog, the sight of persons carrying weapons capable of inflicting injury, &c.,—he immediately turns back and retraces his steps homewards. Again the Neketrala has to be approached in the manner before described, and consulted as to a lucky hour. Were the goiya to meet with a milk cow, vessels filled with water, men dressed in white, &c., when he sets out towards his land, it is considered very propitious.

Assuming he has arrived at his land without the occurrence of any untoward event, the goiya begins to turn up the soil with his mamoty; this process being called *Gevalenawa*. On the following day the goiya entertains such of his fellow-villagers with kaun (rice cakes), kiri-bat (milk rice), &c., as are willing to co-operate with him in the cultivation of his field. At the lucky

hour, these villagers armed with mamoties proceed to the land, headed by the owner, and turning their faces in the direction of Adam's Peak give out the cry of "Ha para hodai" (Ha! a good beginning!). At sun turn the workmen retire for their midday meal. During the time the villagers help the goiya in the cultivation of his field, they are supplied by him with food and other necessaries.

No particular ceremony is observed in ploughing, except that wreaths of sweet smelling flowers are twined round the horns of the buffaloes, and the ploughmen keep intoning the words "Uvé Uvéuvé, Uvé Uvéuvé" which are considered pleasant and encouraging to the animals.

When the field is ready for sowing, the ceremony of *Pela mala Hadanawa* takes place after the following manner:—On the advent of a lucky hour, the goiya leaves his dwelling after having recited a number of religious stanzas, bearing an arecanut flower and a pata (handful) of paddy. Having arrived at his field with his eyes turned towards the favourable region of the sky, he buries the paddy in a corner of a ridge, having first moulded the earth at the spot so as to represent a peculiarly-shaped symbolic figure, and lays the arecanut flower on the top of the mound. On enquiring into the significance of this ceremony, Kehelpanala Pohath Nayake Unnanse, High Priest of Kotmale l'ansale, informed me, that the arecanut flowers were intended as an offering to the gods who are held to have a great love for them, while the paddy is believed to be taken away to provide a meal. After a lapse of five days all preparations are made to sow the field: but a consideration of the ceremonies which attend the sowing of the field I must postpone for another occasion.

T. B. POHATH KEHEL PANALA.

Gampola : Angammana Adikaram Walauwa.

June 26th, 1891.

MANURE VALUATION.

The instructions drawn up by Dr. Aitken, Chemist to the Highland and Agricultural Society of Scotland, for valuing manures, give all cultivators of the soil the means of computing for themselves the commercial value of the fertilizers they use. The calculations are based on the analysis of the manures and on the unit values of the ingredients. The units are based on the market prices at port, the terms being cash including bags gross weight, not including carriages. When these units are multiplied by the percentages in the analysis of a manure, they will produce a value representing very nearly the cash price at which one single ton may be bought in a fine sowable condition. Large purchases may be made on more favourable terms. The units are of course not constant, but are fixed for different "seasons." For season 1890, the units for soluble phosphates are 3s. 3d. in dissolved bones, 2s. 6d. in superphosphates, and an average of 2s. 10d. in dissolved compounds; for insoluble phosphates, 2s. 6d. in Ichaboe guano, 2s. 2d. in genuine Peruvian guano, 1s. 9d. in fish guano, 1s. 8d. in Frey-Bentos guano, 1s. 10d., 1s. 9d., and 1s. 8d. in the three classes of bones, 1s. 9d. in steamed bone flour, 1s. 9d. in dissolved bones, and an average of 1s. 9d. in dissolved

compounds; Ammonia 17s. 6d. in Ichaboe guano, 16s. in genuine Peruvian, 12s. in Fish guano, 13s. in Frey-Bentos guano, 12s., 11s. 6d. and 11s. in the three classes of bones, 12s. in steamed bone-flour, 13s. in dissolved bones, and an average of 13s. in dissolved compounds; potash 3s. 6d. in genuine Peruvian guano, and an average of 4s. in dissolved compounds.

The phosphates (soluble and insoluble), Ammonia and Potash are the only items to be valued.

As an example, suppose in a high class mixture, the analysis shows:—

	Per cent.
Soluble Phosphates	20

GENERAL ITEMS.

Mr. Kumaravellu, who has lately returned after a tour in the North, writes:—"There is little doubt that the Northern Province contains more stock than any other in the Island. The stock consists of bulls and cows, sheep and goats, but few buffaloes. In the Jaffna peninsula, though stock-owners are most assiduous in their attention to their animals, it cannot be said that cattle are at all fed as they should be. The Jaffna cultivator does not raise any fodder crops, and depends for his supply of cattle food on what grass he could get from jungles and uncultivated places. But even this wild grass is only available to any extent at certain times, so that at other times cattle are fed mainly on straw. Goats are allowed to stray about and find their own food, which, however, they do not get very much of. In the mainland on the other hand while there is more pasture land available for cattle, there are, for the area, few cattle-owners."

"Erythrina and tulip (suriya) leaves are also used for feeding bulls and cows as well as goats. The former are got from the live fences or from betel-vine supports, and though they are relished by these animals, they are not suitable for working bulls as not only being not sufficiently nutritious, but as also having a tendency to cause laxativeness. Palmyra leaves are also used for feeding cattle, after being torn into pieces and mixed with straw. A few owners of cattle

breed their own animals by crossing with Indian bulls, but little attention is given to the breeding of sheep and goats."

"Cattle manure is often carefully collected and sold at R3 and more a cart load, but more care can be exercised to prevent manure deteriorating in value from exposure to the weather. It is a common idea among cattle owners and cattle doctors that starving cattle, is the best means of driving away disease. What the origin of this idea, which is embodied in a proverb is, it is difficult to make out. Goats are liable to an epidemic disease, of which the symptoms are cessation of feeding, inflammation of the mouth accompanied by a flow of saliva, costiveness of the bowels, and a blackening of the tongue. The animals die soon after the appearance of these symptoms, but sometimes linger for 6 or 7 days. The cattle doctors have no remedy for the disease, and for the want of veterinary aid, which is required so much here as well as in other parts of the Island, many herds of goats are periodically carried off."

The *Pioneer* seems to think that Dr. Voelcker's conclusions with regard to Indian Agriculture have been rather hasty, and quotes Mr. Benson of the Agricultural Department of Madras to prove that the ryot's systems of agriculture are by no means so perfect as thinks Dr. Voelcker, who "it would seem takes a very rosy-coloured view of the Indian cultivator and his methods."

The *Indian Agriculturist* denounces in strong terms Dr. Voelcker's approval of the system of communal grazing. "It is a matter for deep regret," it says, "that a man of his scientific attainments should have given the support of his voice to encourage an unsound economic system.....a system so utterly unscientific."

The *Times of India*, referring to Dr Voelcker's article on Indian Agriculture in the Journal of the Royal Agricultural Society, says:—It is not only that the article is scrappy and imperfect—these are faults that might have been condoned—but it has a curiously superficial air about it, and paints the system and prospects of Indian Agriculture in hues which, judged by the researches of other practical men, seem altogether too rosy.

The supplement to *The Fireman* of May 1st to hand consists of a description of appliances designed by Messrs. Merryweather and Sons for India and the Colonies. Under irrigation machinery is described the improved high-class light irrigation machine specially made to meet the demand in the Colonies for light and powerful pumping machinery for irrigating purposes. It is particularly adopted for use in situations where transport of heavy machinery is difficult, and where it is required to move the engine about to work at different points. The machine can be made to draw water from a depth, and, if required, force it to a height of 40 feet from the water. The weight of the machine on wrought iron wheels is about 30 cwt., and for conveying "upcountry" it may be shipped in

parts, the heaviest weighing about 10 cwt. The engine is made in different sizes to deliver from 500 to 2000 gallons per minute. When specifications and estimates are required, the following particulars should be given:—1, quantity of water required per minute; 2, total height to which it is to be raised; 3, character of fuel to be used; 4, character of water to be used in the boiler; 5, length of oiling and suction piping required.

Fixed irrigation pumps to be worked by wind power are also supplied by this firm: and by another arrangement a pair of gun-metal pumps are worked by a water wheel pumping part of the water by which the wheel is driven to a height of 50 feet through 1,500 feet of piping, or the wheel may be worked by river water and the pumps arranged to draw from a reservoir of potable water. A fall of 4 feet has been found quite sufficient to do the work, and the whole is so simple and strong, that it will pump quite unattended for days, only a little oil being occasionally required. The cost of this last arrangement, not including any brick-work, is about £40.

Seaweed is a substance of somewhat variable composition. Dr. Ure, in his *Dictionary of Arts*, gives the following typical analysis of the composition of the soluble and insoluble parts of ash of seaweed:—

Soluble Part—

Sulphate of soda	8.0	19.0
Soda in carbonate and sulphuret	8.5	5.5
Muriate of soda and potash ..	36.5	37.5
	53.0	62.0

Insoluble Part—

Carbonate of lime	24.0	10.0
Silica	8.0	0.0
Alumina, tinged with iron oxide	9.0	10.0
Sulphate of lime	0.0	9.0
Sulphur, and loss	6.0	8.5
	100.0	100.0

In Watt's *Dictionary of Chemistry* the percentage of nitrogen in the dry matter of seaweed is stated as follows—Dulse tangle, 1.588; black tangle, 1.396.

The third section of the International Congress of Hygiene deals with the relations of the diseases of animals to those of man. The President of this section is Sir Nigel Kingscote. Papers on the following subjects will be read by noteworthy physiologists, bacteriologists, veterinarians and agriculturists:—The propagation and prevention of rabies; animal parasites communicated to man; the infection of food; infectious diseases of the cow in relation to epidemic diseases in the human subject; the inspection of meat, with regard to the prevention of disease; tuberculosis in all its bearings; the alleged danger of consuming the apparently healthy meat and milk of tuberculous animals; the infectious diseases communicable from animals to man and vice versa; anthrax; the general subject of veterinary hygiene.

It is to be hoped that the representatives of Ceylon will give their best attention to this important section of the Congress.

Received with thanks the Richmond College Magazine for June. We learn from it that Mr.

Paulusz, the Science Master of Richmond College for several years, has severed his connection with the institution, and that Mr. G. C. Lee has succeeded him.

We have also to acknowledge the S. Thomas' College Magazine for May-June.

COLOMBO, AUGUST 1ST, 1891.

[No 2.]

COFFEE [AND TEA] SOILS AND MANURES.

COFFEE in Coorg seems to have far better resisted the deadly influence of *Hemiteia vastatrix* than has been the case in most parts of Ceylon, judging from the fact that Messrs. Matheson &

Co. considered it worth their while to employ a special Agricultural Chemist and to incur very large expenditure in prosecuting experiments in the direction of reviving an industry which with us in Ceylon seems absolutely dying out, in this the twenty-first year since the fungus was first observed in the eastern outlying range of Madulsima. By arrangement with Mr. Pringle, the chemist in question, we commence today the publication of a series of papers he has prepared as the results of his investigations and experiments. The detailed and interesting information afforded in the paper we publish today may be useful to the owners of such coffee as still survives in Ceylon, whether the cultivation of Arabian coffee is ever resumed here, on a large scale or not, and in any case tea and cinchona planters cannot but benefit; for we may take it for granted that, whatever, in the shape of manure at least, is good for coffee, is equally good for the other products, especially tea. We have been in the habit of saying that a leaf-yielding plant like tea must be less exhaustive of the fertile constituents of a soil, than a fruit-yielding plant, like coffee. But let our readers mark the large proportion of plant food taken up by the twigs and leaves of the coffee tree, as shown by Mr. Pringle, bearing also in mind that the tea plant, besides being subjected to an almost incessant plucking process, is periodically pruned after a more severe fashion than that applied to coffee. It being certain, therefore, that, even more in Ceylon than in Coorg, the decomposing felspar and mica fairly keep up the supplies of potash, tea requires as liberal phosphatic and nitrogenous applications as coffee does.

In tea cultivation as formerly in coffee, the con-

clusion generally acted on in Ceylon is, that the best all round manure is a mixture of finely ground or steamed bones and white castor cake. If some superphosphate can be added so much the better. The bones supply the great element of phosphoric acid, with some ammonia; the cake is rich in nitrogen, and contains a little potash, supplies the soil with organic matter in the best possible condition. Mr. Pringle seems to prefer fish to oil cake; and no doubt pure fish is an excellent manure, better oven for tea, we should say, than for coffee, but it is probably more evanescent in its effects than castor cake and does not act to such an extent mechanically on the soil by means of organic matter, which, in the case of the cake, does not at once decompose. Considering the merits attributed to shade in South India coffee culture, surprise will be felt at Mr. Pringle's conclusions in an unfavourable sense. There is a difference, however, between the dry climate of Mysore and the moist climate of Coorg, and between the light shade of *Ficus glomerata* and the dense canopy of the foliage of the jak tree? In Ceylon, long before the fungus rendered every other question subordinate to one which with us was even more than equivalent to phyloxera in vine culture, we had come to the conclusion that where coffee required shade it would be unprofitable to grow it. From some experience we are inclined to believe that tea is far more tolerant of shade, both as regards flushing and flavour of flush; and that the liberal planting of shelter, timber and fuel trees can be carried out on a tea estate, not only without injury but with benefit to the main product grown. We should like to hear experts on this point, and the modified shade as well as the fertilizing effects of the growth of green plants amongst our tea, in order to carry down into the soil nitrogen derived from the air. Is there any danger of fungus from the decomposition of green stuff? We are here reminded of Mr. Pringle's suggestive idea that a soil may get "eick" of one unvarying product, and it may be a question whether this was not one cause of the predisposition of our coffee tree to the attacks of the fungus, and whether the same danger has not to be guarded against in the case of tea, grown, as it often is, in wide unbroken expanses.

Lime applied in moderate quantity occasionally (after other manures have had time to dissolve and be assimilated by the tree roots) cannot but be of value in averting such a consequence, besides its action in loosening the soil, the latter a process which is less necessary in the culture of tea than of coffee. Tea also flourishes in soils where alluminous and ferruginous constituents are in greater proportion than was desirable for coffee. If Mr. Pringle is correct in showing that a substance so moist, heavy and bulky as cattle manure costs generally in production more than it is worth, especially if it has to be carried any

distance, how much less is its production likely to be profitable in Ceylon where our forage grasses are generally so poor and imported food in the shape of gram and gingolly poonac so expensive. On nearly every estate, of course, a few cattle must be kept as milk yielders; and there are estates which find it profitable to employ bullocks for draught purposes. In such cases, the manure is a by-product, and will be very valuable, as will horse manure, when applied near the sheds and stables, but it seems pretty evident that, as a general rule, estates when they need applications of fertilizing matter must rely on artificial manures; and the question to be solved is, what are the best to choose and employ? Analyses of soil, such as Mr. Pringle gives, must be of great assistance. He shows that while nitrogen is specially wanted in one case, it would be simply a costly folly to add it in another. So with lime and in the case of kainit or other potash manure. We suppose that anyone buying bones or castor cake from any of the leading firms in Colombo is guaranteed but certainly a system of public and cheap analyses would be very useful, as new manures are occasionally offered for sale. Mr. Pringle is mistaken in supposing that planters have devoted slight attention and incurred but small expenditure on analyses and manures.* Apart from the employment of Mr. John Hughes by the Ceylon planters and the expenditure of large sums in the unsuccessful combat with leaf-disease, we had, in the *Observer* towards the end of the seventies a series of elaborate letters from a Mr. Tolputt, embodying detailed analyses of Wynad soils and of manure recommended and applied with reference to such analyses. Only a few days ago in going over accumulated papers, we found a series of soil analyses received from the gentleman named, which had been put by for publication at a convenient season. The figures will now be of interest in comparison with those given by Mr. Pringle or those which he may hereafter adduce. Meantime the paper we today publish, although specially devoted to coffee, is just as applicable, in the general principles laid down of adapting manures to constituents of soil shown by analysis to be deficient, to tea, cinchona, cacao, cardamom and even coconut palm culture as to coffee. We can never go far wrong in applying bones and castor cake, in moderate quantities and in due proportion to our soils, at intervals of about three years, whatever the product cultivated may be. Such a potash manure as kainit will be useful on many of the older coffee estates, replanted with tea; and where it can be afforded, we should think it would be eminently beneficial to coconut land, not only for the potash, but for the appreciable quantity of common salt it contains. Lime, bones and kainit, ought, we submit, to largely increase the growth of the palms and the yield of nuts, while the moderate and judicious use of bones, superphosphate, castor cake, fish and in some cases kainit, ought to increase the quantity and improve the quality of tea flush.

COFFEE MANURE.

By WILLIAM PRINGLE, M. S. C. I.,
 LATE AGRICULTURAL CHEMIST TO MESSRS. MATHESON & CO.
 IN COORG.

(Under special arrangement for publication in the "Ceylon Observer" and "Tropical Agriculturist.")

The question of manuring coffee has had little systematic work spent on it, compared with the vast in-

* The late Mr. R. B. Tytler had everything connected with the coffee tree and soil analysed before making up his patent manure, *Sombreorum*.

terests at stake; most planters have been content to use such manures as were most readily come at, with out bothering their heads as to whether they got an adequate return for the money spent on them or not. I have known fine rubbish carted five miles; it could only in very rare instances be worth the cartage.

In selecting a manure to be used on an estate we should be guided by the analyses of the soil, as well as by our knowledge of the composition of the coffee shrub, and its requirements.

One glance at the annexed analyses of South Coorg soils will show that they require very different treat-

	Parts per hundred.		
	A.	B.	C.

* Containing Nitrogen143	.292	.089
Equal to Ammonia174	.355	.094
Moisture in air dried sample	3.24	12.13	1.78

On A and C the great object should be to conserve the moisture by shade, and the use of as much good cattle manure, made by bedding the cattle with leavos and ferns, as possible. Both are rather short of potash, and one cwt. of nitrate of potash (nitro) per acre should be added to the manure; this will supply nitrogen as well as the potash, and C is very short of that most important element.

A, requires nitrogenous manures with potash, but a little bone phosphate should be added to prevent soil exhaustion. The following manure was recommended:—

2 cwt. bone meal
 1 cwt. nitrate of potash

This should be mixed with 1 cubic yard of burnt earth or 2 bandy loads of cattle manure.

It would be a sheer waste of money to apply lime to such a soil.

B, is very short of phosphoric acid bones in fine meal will be the best manure, 4 cwt. per acre will be enough and lime may be used with advantage six months afterwards.

To use oil cake as a manure to such land to say the least would be a waste of money. Lime used before the phosphates have time to act would lead to the rapid exhaustion of the land. It is a case where the indication of the analysis is very clear. On such a land ammoniacal manures used without phosphates would never produce any results commensurate with the expenditure, and would do more harm than good. The land as shown by the moisture is very retentive, drainage is a necessity if the coffee is to be kept healthy, over such land the shade may with advantage be kept very light and thin.

C on the other hand is a poor sandy soil, greatly wanting in moisture, shade should be kept thick, as leaf mould will render great assistance in retaining the moisture; cattle and organic manures will also give results beyond their mere manurial value on such land. In fact on such places cattle manure is invaluable. I recommended cattle manure, 2 tons with 1 cwt. fine bone meal, 2 cwt. pure dry fish, and $\frac{1}{2}$ cwt. nitrate of potash per acre. These examples show how we may be guided in our choice of a manure by the soil analysis, that a knowledge of the power of the soil to retain moisture will assist us in regulating the shade, and decide many vexed questions of the best methods of cultivation to be followed in a given case.

The system of cultivation that might be successfully worked on B would not answer on C: the whole treatment required is different, also the manures. So far I have mentioned, as coffee manures, cattle muck

bones, oil cake, and fish; now let us examine these materials and see what we are dealing with.

Cattle manure is first on the list. Its effects are as much mechanical as chemical, and where it has shown the best results I have generally found the soil possessed a very poor power of retaining moisture as in analysis C. Where cattle are kept solely for manurial purposes, cattle muck is very costly, and does not always pay for the trouble of making it. When made by working bullocks it is a by product, and often represents the sole profit on their keep. If it were not for the muck it would often be just as cheap to hire handies for the estate work.

The following is the actual cost of the upkeep of a handy and bullocks in this district:—

	R.	s.	d.
Gram for 28 days 126 seers @ R50 ½ M...	6	4	4
Straw 168 bundles @ R23 ½ M...	4	6	0
Salt	0	1	0
Bandyman	8	0	0
Oil, shoes, repairs to bandy...	2	0	0
Wear and tear of bullocks...	2	0	0
Interest on capital @ 5 ½ cent ...	1	4	0

R23 15 4

In full work the bullocks and handy oaru R1 per day, and if they work 24 days out of 23 the profit is only 8 pice and the manure. These two bullocks produced in 28 days 1,491 lb. of dung having the following composition when air-dried:—

	Parts per hundred.
Moisture	7.94
* Organic matter and combined water ...	59.92
Oxides of iron and alumina...	1.18
Lime	1.78
Alkaline salts	1.12
Phosphoric acid...	.88
Insoluble matter &c.	28.18
	100.00

* Containing nitrogen539
 Fresh dung contained moisture ... 73.99%

The dry dung is worth at the most for the manurial ingredient it contains R8 per ton, the dung in its natural state about R2. Well bedded with bracken fern it may be assumed as an outside estimate that a pair of bullocks will produce one ton of manure, worth about R2 per ton. The following is an analysis of a first-class cattle manure produced by bedding the cattle with bracken fern, they were gram fed. Kept in a covered shed the bedding and muck were pushed out into a shed below, the urine flowed over the heap.

The sample was taken in March and appeared quite dry, when powdered it just looked like brown sauff.

	Parts per hundred.
Moisture	25.83
* Organic matter and combined water ...	55.23
Oxides of iron and alumina...	1.11
Lime	1.50
Magnesia86
Potash89

Phosphoric acid55
Sulphuric acid13
Chlorine24
Insoluble matter, sand &c....	18.25
	100.00

* Containing nitrogen4)
 Equal to ammonia60%

Such a manure is exceeding valuable on poor sandy soils, but is too short to be of much use in opening up heavy retentive lands, they require horse dung and straw litter to do good. Cattle manure should never be burnt, as its most useful character—its mechanical condition,—is thereby destroyed, and it sinks to the value of wood ashes or less.

We have seen that the manure is costly to produce; and it is equally costly to apply. The following table shows in lb. what 10 (ten) tons first-class gram-fed

cattle manure in its natural state containing 75 per cent moisture will yield; many samples of cattle muck contain as much as 85 to 95 per cent moisture; other samples are hardly cattle manure at all, being chiefly composed of line sweepings and other rubbish of little or no manurial value. The table also shows the quantity yielded by bones, fish and oil cake;—

	lb. per acre supplied by	10 tons	4 cwt.	4 cwt.	4 cwt.
	cattle	raw	pure	oil	manure, bones, fish, cake.
Tri-calcio phosphate	67	226	80	5	
Ammonia	34	18	31	27

Lime	49	3	32	1	
Sulphuric acid	7				
Total	207	251	150	99	

Cost, rupees	120*	13½	9½	11
Cost of application, rupees	30	5	5	5

Total cost, rupees ... 150 18½ 14½ 16

*If the bullocks do not work, gram-fed cattle manure of that quality cannot well be produced for less.

Should the amount put down for the application of cattle manure appear excessive, let the questioner work out the problem on the supposition that there are 1,200 trees per acre and that one basketful is given each tree. Each basket has to be filled, the distance to the tree and back traversed, and the basket emptied. Suppose that the coffee is moderately thick, and that the roads are 100 trees apart, then to reach the centre a coolie

	yards
To the first tree and back	4
2nd	8
3rd	12
4th	16
5th	20
and so on.	
At the tenth tree he has walked	230
20th	850
30th	1,860
40th	3,280
50th	5,100

and by the time he has reached the 52nd tree, he has manured the 23rd part of an acre, and walked three miles.

Taking filling and emptying of baskets into account he will seldom walk a mile per hour. At such work a coolie would consider 100 trees a hard task, and certainly it would be from 10 to 20 times as hard as potting out 4 cwt of manure mixed with 1 cubic yard of burnt earth. The cost of application entered under bones, fish, and oil cake, includes the cost of preparing 1 cubic yard of burnt earth and mixing it with the manure.

This was given me by several managers as two rupees, and for application three rupees so that taking cartage &c. into account it is not safe to estimate less than R30 per acre for the cattle manure. In Ceylon where cattle are often kept solely for manurial purposes the cost is seldom much under R100 per acre, and with the scanty grazing ground of this district it would be difficult to produce any quantity of cattle manure, and the small quantity produced if the animals are well fed and hedged cannot well be made under R12 per ton. So that, except in the case of work bullocks, cattle manure of first rate quality may be dismissed as too expensive for ordinary use, and we must look for some other manure. We find in good pure fish the cheapest native manure. Where first class fish manure is easily procurable cattle manure and oil cake, i.e. castor, Hindy, may be looked upon as expensive luxuries, only to be indulged in where the poverty of the soil demands the use of an organic manure.

Bones decompose very slowly in this district, and steamed bones are preferable to raw on that account, they should also be in the finest meal possible, if an immediate return for the money spent is expected. The use of inch bones in South Georg might be termed, manuring for posterity, as this generation will reap little benefit from them. The coffee tree is not greedy

It does not ask for a large supply of food. A fair average tree at the end of the hot weather weighed 20 lb. and had seventeen primaries and 2,500 leaves; such a tree will yield 5 cwt. of coffee per annum with its accompanying pulp. Materials removed by:—

	5 cwt. Coffee.	
	lb.	Pulp. Leaves.
Tricalcio phosphate	... 4	1 41
Ammonia	... 10	2½ 135
Potash	... 9	6 101
Lime	... 2	1 90
Sulphuric acid	... ½	½ 11

The amount of material taken up by 5 cwt. coffee is very small. That removed by the leaves and prunings is what requires to be replaced by manure as they decompose very slowly, the soluble salts yielded by them are lost in the monsoon rains, and wash. The plant food is not there when the tree requires it to develop its fruit.

Looked at from this point of view, we must, in a manure that has to be applied at the end of July or in August, have all the plant food in an easily assimilable form, and provide fully for the plant's wants. On this basis a coffee manure should have 40 lb. Tricalcio phosphate, 140 lb. of ammonia, 110 lb. potash, and other manurial matters in proportion, if the tree has to depend on the manure alone for the supply of plant food.

But the soil by slow decomposition and disintegration is also supplying food, and the tree appears to be capable of taking up ammonia, or some form of nitrogen compound from the air through the soil by its roots. The great question is what is necessary and how much? To help in the settlement of this question I submit the aggregate results of some of my experiments giving the weight of clean coffee yielded, the results of 1889 and 1890 are added together in the following table:

	MANURE.			
	4 cwt. yield lb. per acre.	8 cwt. yield lb. per acre.	4 cwt. yield oz. per tree.	8 cwt. yield oz. per tree.
Bones	... 833	752	13.77	12.84
Bones and fish...	783	818	12.14	13.12
Fish...	553½	655½	9.90	11.93
Superphosphate	759	794	12.34	11.11
Mineral phosphato...	910	920	13.84	14.90
Ammonia sulphate...	983	712	16.30	12.33
Potash nitrate (nitre)	813	908	13.38	16.79
Super and ammonia	713	744	11.41	14.34
Super and nitre	773	834	13.05	12.23
Minerals and do	648	793	10.45	13.84
Kainit potash salts...	607	544½	9.18	9.02
Average...	761	779	12.35	12.95

The average yield from the 4 cwt. of manure is the same as from 8 cwt. practically speaking: at any rate there is not sufficient difference to pay for the extra manure used. The results were almost entirely controlled by the shade where it was thin the results were good, and *vice versa*. This was particularly noticeable in the case of ammonian sulphate where 4 cwt. yielded so much better results than the 8 cwt. One of the 8 cwt. plots was under dense jak shade and the results were remarkably poor, worse than an unmanured plot not thirty yards off where the shade was thin. Nitre, the 8 cwt. had the advantage of the thin shade and the results are just the reverse of the sulphate of ammonia. Bones present a very curious illustration of the great effect of shade, 4 cwt. gave 13.77 oz. per tree, and 8 cwt. only 12.84 oz.

When 4 cwt. of fish were added to 4 cwt. of bones the yield was only 13.12 oz., considerably less than when the bones were used alone. There was only 1.12 lb. of an acre, 100 trees on each of three estates, or ⅓ acre in all under each quantity of each manure, and on

these small plots shade has had the power to mask and control the shade, but in the aggregate they show that under shade, 4 cwt. of manure will produce a good result as 8 cwt., and it is evidently folly to use more.

From the preceding data and analyses, it would appear as if the chief requirements of the coffee tree are phosphoric acid and nitrogen; unless the surface soil has been lost there would appear to be but a small demand for potash.

Potash salts are very soluble in water, and appear to be easily assimilated by the plant, they are abundantly supplied by the slow decomposition of thin feldspar and mica schist in the rocks, and the stony matter of the soils, together with lime and magnesia, but the accumulation of the salts in the land is prevented by the monsoon rains.

If they are required as in analysis C I would advise the use of ferus for bedding cattle, particularly bracken where such are procurable. The ash of the bracken fern, according to Lester Arnold confirmed by John Hughes, contains:—

Potash	... 42 per cent
Phosphoric acid	... 10 "

and is a very valuable manure wherever potash is required, and will well repay the trouble of collecting the fern.

Should ferns be unprocurable and the addition of a potash salt necessary, I would recommend kainite. The buyer should stipulate for 25 per cent sulphate of potash, at the very least. But potash is not necessary as a rule, and should never be used in excessive quantities, as it increases the quantity of pulp at the expense of the bean. This however does not apply to nitrate of Potash, which acts more like ammonia sulphate than any thing else. Wherever there is plenty of nitrogen in the soil the leaves of the trees are large and of a beautiful glossy green, but the bean is small unless there is a fair share of phosphates present also.

This leads to the conclusion that the coffee tree must have nitrogen and phosphates in the manure; whether potash should be included or not depends greatly on the nature of the soil. I would say that it was unnecessary with a retentive soil like B. Now with some soils, the analysis shows the weak spot at once and we can easily select a single manure to meet the exigencies of the case; in others the manure must be diffusive to cover the whole range of the necessities of the plant and the poverty of the soil.

The following represents a good type of a diffusive manure:—

1 cwt fine bone meal
1 " pure fish
1 " superphosphate of lime 40 per cent soluble
½ " sulphate ammonia
½ " kainite 25 per cent sulphate of potash

This applied after the heavy rains are over at the end of July or August will supply plant food in a form immediately available for the plant's requirements, and will greatly assist in the perfect development of a healthy bean. It is not stimulating, but holds the plant food in varying degrees of preparedness ready for the use of the plant from season to season. 4 cwt. per acre mixed with 1 cubic yard of burnt earth or two good loads of cattle manure is sufficient for 1 acre per annum. It is well suited to the raising of supplies.

In conclusion I must draw your attention to the advantages of green manuring. Nitrogen is a most expensive item in manures, but certain plants readily take it up from the air in some way little understood at present. Lucern, clover, mustard, &c. &c., may all be planted under the coffee they are excellent manures, as they derive most of their nitrogen from the air and send their roots deep into the ground in search of food. The growth of white mustard is so rapid that it may be used to choke out other weeds, by sowing two or three crops in succession and forking them in. Green manuring, if carefully carried out, should supply all the necessary feed for the bullocks used on the estate, and protect the soil from the action of the sun during the hot weather in the dry districts.

This system of cultivation is specially suited to poor soils such as shown in analysis C.

It will also improve the condition of heavy and retentive lands. If put in force the land should be limed once in three years or so, and the plants should be grown in rotation. In this way it will be possible to clean the land and free it from an excess of injurious salts. The coffee tree is wanted as a permanency, and the best way of keeping the land healthy is to grow a rotation of annuals under the coffee, and as far as possible a rotation or diversity of shade over it. Whenever a shade tree shows signs of becoming a surface feeder it should be rooted out; slow-growing shade should be put in to take the place of the quick-grown shade as it dies off.

By these measures it will be possible to prevent the land in a great measure from becoming coffee sick, which it does by becoming infested with microscopic fungi and bacteria when kept under one crop too long.

The investigations into potato and vine diseases, and other sickness show this to be the main cause of land refusing to bear one crop in continued succession. It is from this cause that the greater number of coffee supply plants fail, white mealy bug assisting in the devastation. All these pests can be eradicated by proper treatment at the right season. W. P.

PLUMBAGO AND MICA.

For some time Messrs. Parry & Co. have been negotiating with the Travancore Government for the grant to them of a monopoly for mining for plumbago and mica in certain selected taluks in Travancore territory, which were reputed to be rich in these minerals. These negotiations have so far progressed that a draft agreement has been drawn up, which, together with the criticisms passed upon it by the Advocate-General, and the remarks of the Madras Government thereon, has been forwarded to the Government of India for final orders.—*Indian Agriculturist*.

JAVA CINCHONA, CACAO AND TEA EXPORTS.

From the Batavia Exchange Report we see that Java continues to more than make up for the falling-off in Ceylon exports of bark. From 1st July 1890 to 30th April last, ten months of the year, Java has sent away—almost entirely to Holland—no less than 5,718,577 lb. of "Private" estates bark and 484,087 lb. of Government gardens bark against 3,709,648 and 445,940 respectively during the same period of 1890. This shows a very big advance considering that 2 million lb. of Java bark is equal in the average to 4 million lb. of Ceylon bark. The Java exports are in Amsterdam lb. each of which is equal to 1.09 lb. avoirdupois. The comparison for several seasons for the ten months' period is as follows:—

	Total Cinchona Bark,	
	Private	Govt.
	Amsterdam	lb.
1st July to 30th April...1890-91...	5,718,577	484,087
Do. ...1889-90...	3,709,648	445,940
Do. ...1888-89...	2,989,780	723,491
Do. ...1887-88...	2,353,426	532,687
Do. ...1886-87...	1,357,576	571,320

Java Exports—apart from Cinchona—do not compare nearly so well. Of Coffee only 224,121 piculs private and 81,599 Government have been exported in the ten months against 477,849 and 394,272 piculs respectively in 1889-90, showing an enormous falling-off this season, in the case of private crops by over 50 per cent, while of Government coffee scarcely one-fourth the previous season's export goes in 1890-91. So far from coffee reviving in Java, it is therefore evidently going back very grievously, the total export in 1890-91 probably not exceeding

400,000 cwt. against 1,200,000 cwt. in 1889-90 and 1,100,000 cwt. in 1888-89.—Pepper also shows a falling-off of about 30 per cent this season so far, in quantity exported.—Cocoa or cacao shows a sudden and very large increase to 10,600 cwt. in the ten months, against only 1,360 cwt. in the same period of 1889-90, and 1,100 cwt. the season before. Cacao cultivation is now in Java; but it is evidently going to succeed and Ceylon planters may look out for a serious rival in this product.—In Tea not much progress seems to be made. Here are the exports for ten months of the several seasons:—

		Kilogrammes.
1890-91	...	2,893,277
1889-90	...	2,548,669
1888-89	...	2,770,900
1887-88	...	2,562,072
1886-87	...	2,722,736

These returns are in kilogrammes, so that one-tenth should be added for English lb. making 3,171,604 lb. export for ten months of the present season.

NOTES ON POPULAR SCIENCE.

BY DR. J. E. TAYLOR, F. L. S., & C., EDITOR OF "SCIENCE GOSSIP."

A German chemist and physician has recently demonstrated that there is an increase of nitrogen in the perspiration during excessive muscular work over and above that normally excreted. Another experimenter has shown that the output of nitrogen and urea are closely parallel. The increase of both is most marked during working hours, and it takes some time to subside afterwards.

It is now generally concluded that the little nodules found on the roots of leguminose plants contain bacterial organisms which have the power of assimilating free nitrogen, and that this is the true reason why this order of plants obtain part of that valuable gas directly. Professor Frank thinks there is only one kind of nodule organism common to all leguminose plants, and that it is present in all natural soils. The relationship is one of symbiosis.

Professor de Candolle, the distinguished French botanist, has given a new and original explanation of certain monstrosities in flowering plants. Some specimens were sent him in which the flowers were borne on the upper and lower surfaces of the leaf. The explanation hitherto given of this phenomenon is that there has been an adhesion (or want of separation) between the flower-stalks and the adjacent leaves, so that they have grown together. Professor de Candolle, however, is of opinion that such inflorescences are real outgrowths from the leaves, and not axillary shoots growing and fusing with them. He regards such examples as proofs that botanical distinctions between stem and leaf are purely arbitrary.—*Australasian*.

HEMILEIA VASTATRIX.

(To the Editor "Madras Mail.")

Sir,—“Nilgiri,” in your issue of the 2nd instant, writes about “two different gentlemen” having found the cure for leaf disease. If “Nilgiri” includes me in that number I can answer his questions satisfactorily. The remedy I use will cure leaf disease. Invariably one application will be sufficient; but at times a second application may be found to be necessary after a couple of years. The cost per acre, including labor, will not exceed Rs20. It is impossible to eradicate leaf disease from any particular estate, when thousands of acres round it may be affected with the pest; but the remedy I have, has in every instance cured the disease from the parts applied to, sufficiently to enable the trees to yield fair crops for years.

Coonoor, 4th June.

C. E. P. VERNER.

[As we have so often remarked, Mr. D. Morris's

lime and sulphur curo was sufficient to clear an estate of the fungus, but it soon returned and was as virulent as ever. Hope for coffee would, therefore, seem to rest in the gradual wearing out and final disappearance of the disease.—Ed. T. A.]

PLANTING IN PERAK.

Perak, notwithstanding its productive soil and suitability for planting enterprise, shows no great progress in the cultivation of the ground. The difficulty of procuring labour has been a sore hindrance in the way, but there is of course some little prospect of this check being partly removed if the Straits Government will do anything with the Labour Commission report other than pigeonholing it. One great obstacle however arises from the short leasehold tenure of the land available, and there are other minor discouragements in the way of selectors. The Perak Government, to attract pioneering planters, have issued a circular, which we published some days ago, throwing open land on more liberal terms, but on conditions which hold good only for the first ten applicants who can pass muster. The chief feature of the new departure lies in the granting of leases in perpetuity with no premium and a quit rent of 20 cents an acre after ten years free occupation, the area under lease being 1,000 acres in one block or in blocks of not less than 500 acres. The tenor of the circular infers that perpetual leases will be given only to the first ten approved applicants, but the principle once admitted calls for wider application. The privileged ten would enjoy an invidious distinction which will only stir bad blood. Now that the idea of short leaseholds has been attacked, the Perak Government would best consult its interest by making the principle of long leasehold of universal application. Under perpetual leases with law rents, and ample securities against monopoly, the agricultural land of Perak should attract planters of the right stamp.—*Straits Times*, May 10th.

PRECIOUS STONES.

Large quantities of inferior rubies and sapphires always find their way from Siam to Ceylon, the dealers generally mixing them with better qualities of the same descriptions obtained in the island either for export to the London and Paris markets or for sale locally. Of late, the so-called alexandrite has been introduced here from Siam principally in the rough state. This stone (probably chrysoberyl) has all the appearance of the Ceylon alexandrite, but it does not display the brilliant red of the genuine article when exposed to artificial light. Anyhow I understand that large sales have been made at extravagant prices, and even experts have been deceived to some extent. The stones find their way to the gem districts where dealers from all parts congregate, and are more readily purchased under the impression that they come from the adjoining pits. The home of the Ceylon alexandrite is the Weligama Koral; and hitherto all the best finds have been secured from this district alone.—*Cor*

CINNAMON; QUALITY V. QUANTITY.

This question raised by our Vayaogoda correspondent in Tuesday's (March 3rd) issue, as to the wisdom of the policy of manufacturing fine Cinnamon, after the manner that has become fashionable, is deserving the serious attention of Proprietors. It is well known in the trade that, under the influence of competition, quilled bark has become finer and finer for years past, until now, as many as forty quills of the finest quality go to a lb., as against, perhaps, half that number between 10 to 15 years ago. The labour of making 40 quills is, of course, greater than that of making 20, and the scale of remuneration to peelers has increased, in some estates at least, in proportion. In most, however, the maximum rate of 16 cents per lb. for the finest quality holds, and the earnings of the peelers—which always seemed to us excessive by the light of the prices which their manufactures fetch—have decreased. Through the influence of competition and of advances, they have been obliged to adapt themselves to circumstances, and now practically do double work for the old wages. The question raised is not, however, one of wages, or of the margin of profit left to those who pay high rates to secure fine Cinnamon; but of the effect of the system on the property. Skill alone cannot produce quills over 3 feet long which average 40 to the lb. The bark to be manipulated must be fine and tender. Does not the cutting down of tender shoots affect the vigour, if not the vitality, of the bush, and thus reduce the productiveness of the estate? It is reasonable to suppose that these results would follow, though we are unable to say whether the estimate of our correspondent is correct, that the productiveness of estates has fallen off from 20 to 40 per cent within the last 15 to 20 years. If there has been such a decrease, the question may arise, to what extent fine cutting has to answer for it, and to what extent the mode of cultivation adopted. Nowhere, so far as we know, is Cinnamon regularly manured. All that the bushes receive are the leaves and the weeds which are buried. The equivalent of the sticks and the bark that are removed, season after season, is not returned; and in these circumstances could the productiveness of estates be maintained?

Confining ourselves to the effect of deterioration from fine cutting, the financial question is by no means as easily disposed of as would be the case with products for which there is a growing demand. The productiveness of an estate is maintained, not for the honour and glory of large crops, but for the larger profits it would yield the proprietor. In the case of Cinnamon, an appreciable increase in the output of the bark—say to the extent of 20 to 40 per cent., suggested as the falling off—might prove a very doubtful benefit. The over production of Cinnamon is a fact, and is chiefly responsible for the fall in prices; it is also a fact that the increasing fineness of quills has not led to any advance of prices. On the contrary, the finest qualities, which entail double the labour in preparation as compared with 20 years ago, realize only about a half the prices which the corresponding qualities fetched then. The lower qualities hardly leave any margin of profit. If the abandonment of fine cutting should result in larger crops, the immediate effect of an addition of 20 to 40 per cent to our Cinnamon exports would probably be a further drop in prices by about 20 to 40 per cent. In these circumstances, we are unable to say that proprietors are doing unwisely in aiming at high prices for their crops, instead of endeavouring to main aim a productiveness which would not add to the value of their lands. It is quite conceivable that larger exports and still lower prices may lead to the abandonment of the worst lands; but even if little gardens worked by their owners will not always be deemed profitable and therefore maintained, the combination to secure that end is hardly within the bounds of practical politics. Abandonment of patches may follow as well from the present system. The question discussed, however, points to the double disadvantage of Cinnamon cultivation. Its profits are not large, and this mode of earning them threatens diminishing profits! —Local "Examiner."

* SULPHATE OF COPPER AND POTATO DISEASE.—There is no question that the disease may be controlled by the use of copper solutions, but, judging from the prevalent apathy in such matters, it is questionable whether our growers will think it worth their while to take any steps in the matter. In the Reports of the Connecticut Agricultural Experiment Station we find a report of an experiment, in which five rows were treated on August 10, other rows remaining untreated. The sprayed rows remained green, whilst the others were dead and black. On September 24, when the tubers were lifted, those which had been treated were practically free from disease, while the others were considerably decayed. The untreated rows yielded 3½ bushels per row, these sprayed supplied 6 bushels.—*Gardeners' Chronicle*.

FRUITS FROM WESTERN AUSTRALIA.

It would appear that we are soon to have importations of various kinds of fruit, Potatoes, and Maize from our youngest Australian Colony. The midland Railway Company in that colony extends now some considerable distance from Perth, and the lands abutting on the line have in some places been brought under cultivation to some extent. A small collection of the products of these farms and gardens was exhibited at the offices of the railway company above-named at Winchester House, Old Broad Street, on Thursday and Friday last, which we had the pleasure of inspecting.

The apples were a very well-grown lot, and showed in their fine smooth skin and freedom from speckiness the genial climate in which they had been grown. The kinds were apparently Blenheim Orange, Pott's Seedling, Tower of Glamis, Northern Greening and Yorkshire Greening.

The only Pear shown was William's Bon Chrétien, very large and highly coloured. Fine Quinces were also observed.

The Grapes were a thin-skinned white variety, with a good deal of the flavour of the Muscat of Alexandria. These last-named fruits had travelled indifferently, owing to their not being properly packed. With so good a climate as that of Western Australia, the manufacture of raisins would be more profitable to the growers than exporting unprepared Grapes, which are scarcely fitted for a journey occupying six to seven weeks. Ripe Grapes fetch in the colony about 1d. a lb. Wine making is, we believe, already an industry that is carried on in the colony.

A sample was shown of the Giant Rocca, a nice Onion of mild flavour, but one that does not keep for any great length of time; however, it had stood the warmth of the passage through the tropics very well.

It was a surprise to find Pomegranates fully $4\frac{1}{2}$ inches in diameter.

Some of the Potatoes—kidneys—were of nice marketable size, whilst others were very large and deep-eyed. Evidently the merchants do not make good selections of these tubers for their colonial customers. The price of Potatoes ranges from 20s. to 40s. per ton in the colony. The heads of Maize, both red and white varieties, were of fine size and thoroughly ripened.

The land on which these varied productions were grown consists of a sort of ironstone sand mixed with something of the nature of peat, but in a very fine state, and intimately commingled with the sand, at least it was in the sample shown. It contains no stones. Most of it had, previously to the railway being constructed, been covered with scrub or timber, and at present is in no need of manure, as the various products attest.

In the room where the fruit was laid out was shown the model of a nugget of gold that had been found at Shaw's Falls, which weighed 393 ounces. The winter climate of much of the colony resembles a favourable winter in Cornwall or Devonshire, frost being very rare, and snow laying even inland only a few hours. Of course on the mountains, some of which reach a height of 3000 feet above the sea, it lays nearly the whole summer.—*Gardeners' Chronicle*.

KEW GARDENERS ON THE NIGER.—The last number of the *Kew Bulletin* contains an account of the British protectorate on the Niger, and the efforts made to develop the natural resources of the district. To this end, two Kew men, George Woodruff and H. E. Bartlett, were appointed to take charge of the Botanical Station. Both men unhappily died, but amid the numerous formal and official letters which occupy so much space in the *Bulletin* are interesting extracts from private letters sent home by the two pioneers above named, and which give a good idea of the state of affairs at Sierra Leone, and of the appearance of the country. The *esprit de corps* manifest in these letters is very pleasant, and so are the hopefulness and sense of duty. These, however, were not sufficient to ward off remittent fever, to which both these young men unfortunately succumbed.—*Ibid.*

THE AVOCADO PEAR.—The *Revue Horticole* states that a plant of this species, *Persea gratissima* (a true Laurel not a pear), has produced edible fruit in the open air, at Golfe Juan, near Nice.—*Ibid.*

THE GRAPE: AN ORIENTAL LEGEND.—Four Travelers, an Arab, a Turk, a Greek, and a Persian, says *The Canadian Horticulturist*, met at a city's gate; it was decided that one of them should take the combined moneys of the four, and purchase for the common stock the food which they needed; but they differed each from the others as to what food should be chosen: the Arab insisted that no food was so sweet and nourishing as the agub, while anghar was the food the Persian desired; the Turk said that azum was the only thing which they should eat, while the Greek contended that symphalion was the choicest of all the foods which men could eat. As they thus quarrelled one with the other, before their eyes a gardener passed with grapes. "See, anrb!" cried the Arab. "No, it is anghar," said the Persian. "This is azum," said the Turk. "That is my symphalion," cried the Greek, and so they ate their grapes in peace.—*Ibid.*

Kew.—Fifty years ago, says *Garden and Forest*, the British Government, principally at the solicitation of the then Duke of Bedford, a man famous in his time for his enlightened enthusiasm in gardening, which made Woburn Abbey one of the great gardens of England, determined to convert the old gardens and pleasure-grounds surrounding the royal palace at Kew into a public botanical establishment. Sir William Hooker was invited from Glasgow to manage it. He brought with him a European reputation as a botanist, unflinching zeal, industry, and enthusiasm, a fund of sound Scotch common sense, the friendship and confidence of all naturalists, and the largest botanical library and herbarium which had at that time been made. His reputation and the importance of his collections at once attracted botanists to Kew from all parts of the world. Their visits benefited the establishment, and plants, specimens and books poured into it from all sides. The scientific character of Kew was thus established, and it is this high character that has given it the lead it has long held among the gardens of the world. Sir William Hooker gave the remainder of his long life to Kew, and devoted all his energies and resources to its welfare. His son, a man more famous than the father, succeeded him, and under his administration Kew gained wonderfully in every direction, especially in popular favour. The second Hooker retired from Kew a few years ago full of honours, handing down the management of the garden and all the family traditions to a connection by marriage, under whose wise and broad management it is growing now still more rapidly than ever before in usefulness and beauty. In no other spot in the world can so many different plants be seen growing; the museums of economic botany are unequalled, the herbarium is the most extensive that man have ever made, and the library is unsurpassed. This is the work of fifty years, carried on by men of extraordinary ability and world-wide reputation, working under the most exceptionally favourable circumstances, and with the whole British nation behind them. Kew has received many gifts of great value, and is receiving such gifts every week. It costs, however, to carry on the establishment, 75,000 or 80,000 dol's, a-year. The cost of all sorts of garden labour in England is not more than half what is paid for such labour in the States, and everything connected with a garden costs less there than it does here. If, then, Kew furnishes the ideal at which the promoters or the projectors of the new garden aim, they must realise that this can be reached only by the expenditure of a great deal of money, and that even with all money needed, such results as the people of New York have the right to expect, can only be brought about slowly, and with the aid of unusually favourable conditions. Something can be accomplished with 250,000 dol's, but this amount is only a beginning, if New York expects to rival London, or St. Louis, or Boston in its Botanic Garden.—*Ibid.*

THE DUTCH MARKET.

Amsterdam, May 30th.

All the analyses of the cinchona-bark sales, which will take place in Amsterdam on June 11th, 1891, have been published now. The manufacturing bark contains about 10 tons sulphate of quinine, or 3.87 per cent on the average, divided as follows:—About 1½ tons contain 0.1 per cent; 18, 1.2; 53, 2.3; 70, 3.4; 38, 4.5; 323, 5.6; 19, 6.7; 6, 7.8; 23, 8.9 per cent sulphate of quinine.—*Chemist and Druggist*.

TASMANIAN FRUIT IN LONDON.—Considerable interest was shown in Covent Garden Market, on Friday in last week, upon the arrival of the first of the real Tasmanian Apples, the fruit recently received from the Antipodes being from Australia proper and New Zealand. Apples consigned to Mr. Duthoit, a city merchant, had the distinction of being the first to be sold, the fruit realising from 16s. to 25s. per bushelcase, and being in splendid condition.—*Gardener's Chronicle*.

THE LOCUST PLAGUE continues unabated in the Punjab. Government indeed appears to have taken some measures to prevent its spread, but they are evidently altogether inadequate; and as a natural result much sickness is prevalent, the water contaminated by dead locusts having brought in a fever.—*Madras Times*, June 4th.

COUNTING COCONUTS IN THE HERVEY ISLANDS.—The Report of the Australian and Polynesian Races Bibliography Committee of the Australasian Association for the Advancement of Science contains a memoir on the people of Mangaia (Hervey Islands) by the Rev. W. Wyatt Gill. It embodies important original evidence as to the practices associated with birth and childhood, maturity, circumcision, and marriage, the tribal, social, and domestic customs, the doings of wizards, the superstitions relating to death and the spirit world, and the mythology of the people. A list of numerals is appended, from which it would seem that they are able to count comparatively high numbers, though the word "auere" for hundred is adopted from the English. Coconuts from time immemorial tied up in fours, five of which make one "takau," and names are given for multiples by ten up to four stages beyond, so that they are capable of counting a "tini," or 200,000 coconuts. Mr. Gill also gives a brief analysis of the grammatical structure of the language.—*Athenæum*, May 30th.

COFFEE IN SOUTHERN INDIA.—If a correspondent of the *Madras Times* is to be believed, our staple is not nearly in such a declining way in Southern India as the official figures we published the other day would indicate. The criticism on these is as follows:—

If these figures were correct, it would mean that nearly 60,000 acres of coffee had gone out or been abandoned in four years, viz., 11,000 in Mysore, 9,500 in Coorg, and 38,000 in this Presidency. Taking Coorg for instance, during the last five years, more land has been opened than abandoned, and 9,500 acres probably represent very nearly the total acreage of abandoned coffee in the province. As for the Madras Presidency, the settlement of Wynand no doubt caused the official returns of land under coffee to be set down at a good deal lower figure than previously, but according to the latest returns there are stated to be 76,000 acres under cultivation, and I should very much doubt if all the coffee land abandoned, in Mysore during the past ten years comes to anything like 11,000 acres. Mysore and Coorg are exceptional districts; but surely the process which has brought coffee land down from 250,000 to 50,000 acres in Ceylon, has had its parallel to a great extent in the Wynand districts. In Travancore, we know it has been so.

FUTURE OF COFFEE.—The *Diario Popular* (Brazil), of the 30th ultimo is informed by a person who has recently visited some of the coffee districts of S. Paulo, that the next coffee crop in that State will reach 3,500,000 bags, and that within five years the annual production of coffee in the State will amount to 8,000,000 bags.—*American Grocer*.

SCENT FARMING promises to be a very profitable industry in Victoria, according to the newly-issued report of the Royal Commission on vegetable products. The climate and soil of the colony are declared to be particularly well suited for the cultivation of perfume-yielding plants. Already scent farms are springing up, and the day may not be far distant when star of Roses or the like may come to us from "Britain of the Southern Cross."—*Gardener's Chronicle*.

SUN-DRIED CEYLON TEA AND OVER-FIRING.—Messrs. Rueker & Boncraft in their latest Tea Circular (May 28th) offer remarks worthy of the general attention of planters, thus:—

The fall in prices has, as we anticipated, led to brisk buying on the part of the trade, and we consider that lost ground was recovered at auction, perhaps to the extent of ½d per lb., on the lower grades. The present range of prices, considering the reduction of duty, the increased consumption, and the absence of competition, from Indian Teas, is not such, we think, as to deter tree buying.—The very heavy flushing in April led, we are told, to hasty preparation for shipment, and doubtless had something to do with the lower quality apparent in this month's assortment; but we look for improvement, and already the Teas coming to hand are better.—We have seen today a sample of fine Ceylon Tea sun-dried only. This tea has been slightly fermented, but the sun has apparently had enough power to dry the leaf, to "fire" it in fact sufficiently to arrest fermentation, and the tea is in perfect condition. We submit this goes far to support our contention that as a rule Ceylon teas are fired too much or too long, more at any rate than is necessary for their keeping qualities.

CAEKING AND CROWING.—The *Pioneer* deals with Mr. Romanes after an amusing fashion, and we quote as follows:—

The world has hitherto taken the crowing of chanticleer and the cackling of the common or barn-door fowl upon trust. It had never occurred to any one to suppose a time when peradventure the cock did not crow. Why the hen cackled, or whereunto the cock crew, were questions that were never answered because they were never asked. In these latter days, however, if there is anything which shall not be revealed it will certainly not be for want of the asking; and it has occurred to the inquiring mind of Mr. George Romanes, the well-known biologist, to inquire whether the crowing of chanticleer may not have been evolved by contact with the refinements of the barn-yard, much as some ladies will find their voice only when there is present a sufficiently distinguished company. Mr. S. E. Peal writes from Silhasgar, Assam, to say that in the extreme east of Assam, on the Upper Dikang River, he has often heard the wild jungle cock (*G. ferrugina*) crowing. He admits at the same time that the voice of the wild fowl is "thinner, more wiry and high pitched;" and he adds the interesting observation, "Eggs found in the jungles are often hatched under domestic fowls, and hence these are frequently crossed, and the crow of the cock varies much in consequence." Thus, while there was probably never a cock that had not a crow in him, a judicious crossing of the fowl of the jungle and the fowl of the barn-yard might result in an infinite variety of crow; so that Professor Romanes has still a great field for experiment and investigation.

We have yet to learn what Mr. Romanes has to say to the information sent to him from Ceylon which goes to show that when the domesticated fowl commences to lay away from home in the jungle, she, like her wild sister, ceases to cackle. Mr. Romanes had better pay a visit to the island to investigate the matter thoroughly.

COFFEE IN EASTERN JAVA.

In taking over from the *Singapore Free Press* an interesting account of a trip to the eastern portion of Java, the scene far more of sugar than of coffee cultivation, we cannot help feeling surprise at the sanguine account given of coffee culture near Surabaya and the utter absence of any reference to the existence of leaf-disease, although we know that only more slowly but not less surely than in Ceylon and India the deadly fungus has lessened the production of coffee generally in the great Dutch colony. We are also struck by the violent contrast in the production of coffee estates in immediately following years. For instance, Limburg fell from 1705 pikuls in 1884 to 500 in 1885, and from 5,700 in 1889 to 1,200 in 1890, and yet it was confidently anticipated that this place would give 11,000 pikuls this year. What, also, are we to say to Mirgin's giving 5,620 pikuls in 1888, sinking to 532 in 1889 and recovering to 2,531 in 1890. But surely leaf disease, as well as over-bearing, was at work to account for such an enormous fall in the case of Kati Manis as from 8,000 pikuls in 1888 to 3,100 in 1889 and a miserable 530 (not equal to 1 pikul per bouw) in 1890! Crops varied greatly in good and bad years in Ceylon, but surely there never was such an experience as this? Manure, it will be observed, was not a factor in producing the larger crops; and as the volcanic soil could scarcely require time to recuperate, we must attribute the inequalities to seasonal and meteorological influences, as leaf disease did not operate. A bouw is about equal to $1\frac{1}{2}$ acre we believe, and a pikul to 133 $\frac{1}{2}$ lb. In the case of Limburg, therefore, 11,000 pikuls would be equal to somewhat over 2 pikuls per acre.—The story of the pythou, 30 feet long, which allowed itself to be caught as described and which lived in water in its osse (certainly it must have been a big one), is rather more wonderful than the statements about coffee which rest on authentic figures. The author of the monkey-flesh and monkey soup practical jokes, must have had original ideas of hospitality. The account is lively throughout.—Since writing this, we have seen the figures for the coffee exports from Java this season given two days ago, showing a woeful falling-off.

A PEEP AT OOSTHOOK (JAVA).

(From a Roving Correspondent.)

COFFEE IN EAST JAVA.

There are three passages from Singapore to Java—the Banca Strait, the Gaspar Strait and the Carimata passage. Going by the former you are in sight of land all the way; and the passage is more or less devious. For the last-named you go right out to sea and after passing Lingga on the right and Carimata on the left you shape a course direct for Soerabaya and sight land no more *en voyage*. This was the passage our captain chose as being the shortest.

On Wednesday we were told that Java mountains were in sight at 10 a. m. but we could see nothing till afternoon. It was strange to notice when we get into shallow water the distinct line that separated the very blue deep sea from the very yellow shallow water with a muddy bottom. As Soerabaya is approached all sorts of strange looking craft appear in sight. Some have a triangular sail that looks like a striped blanket, others have two sails which look

like broken butterflies' wings. Most of these belong to the island of Madra, just opposite to Soerabaya and which has a very large fishing population. We approached Soerabaya by the Western passage between Java and Madura. This has only a depth of 18 ft. so that large steamers have to circumnavigate Madura and get to Soerabaya by the eastern passage, thus adding nearly 400 miles on to the run from Singapore.

At 6 p. m. we were at Soerabaya, and before the anchors were down we were boarded and taken possession by a kind friend who would take no denial, and carried us off to his hospitable abode.

Soerabaya is a "slummy" looking place—narrow streets—lots of mud and the roads rutty and bumpy enough to shake the liver out of one! To the stranger passing along the streets two things are especially noticeable; first the marked absence of Ohioese (happy Soerabaya!) and secondly the happy, contented and intelligent look of the natives of the place—from a cursory glance I should say a much superior type to the Javanese we get in the Straits.

To Soerabaya I was given some coffee figures which fairly took my breath away. I have more to collect and will give the whole lot together. At present I am *currente calamo* and *currente jalano*!

I was commissioned to take an invalid to the hills, and on enquiring was advised to go first to Prigin—elevation about 2,000 ft. From a suburban station of Soerabaya we sailed to Forrong, leaving at 7-45 a. m., arriving at 9-6 a. m. Thence in pony carriages a three hours' drive to Prigin where we arrived in time for dinner. It rained nearly the whole way, but cleared up just before our arrival when we found the air to be just delicious. The railway fare, first class, from Wonokumo (suburban station) to Forrong $\$1.60$ and the pony carriage to Prigin is $\$4.50$; each carriage can take two passengers and one small box or bag. The Hotel at Prigin is small, but clean and comfortable; and the food abundant and good. There is a fine swimming bath, about 30 ft. long and 15 broad, but after the water of the plains, the first plunge gives one a decided shock. There are always ponies at the hotel, and there are said to be many pretty rides in the neighbourhood, but I had no time to explore.

The road from Forrong to Prigin is lined on either side with paddy and cane fields. Both show a most luxuriant growth; and the soil in appearance is wonderfully rich. The only land I can compare it with is the very best of the Fen country in England.

The country appears to be very thickly populated, the markets that we passed being crowded with women buying and selling; in some cases I should say there were over 2,000 present in one market. It is a quaint sight to see them riding along sitting astride their ponies, with a big pauzier hung on either side.

To show how these Javanese drivers rattle their ponies down hill, I give the following:—From Forrong to Prigin took us three hours. The return journey was done in one hour and twenty minutes! The steep portion of the ascent was done in one hour and three quarters, with much whipping and bad language. The same on our return was done smiling in twenty-three minutes.

Before I forget it the etiquette of calling in Soerabaya seems curious. The correct hour is from 7 to 8 p. m. and you have to give notice if you intend to visit for fear of finding the ladies in sarong and kabaya. This last was told me in a whisper, so please print accordingly.

From Prigin my first point was the mountain called the Kloet. I railed to Kediri, where I was met by a friend. Our programme was to take what is by courtesy called a dog-cart for 8 miles, and then ride 12 miles on to the coffee lands. *L'honneur propose* &c. It was the Javanese New Year; and no dog-cart was to be got. After a long wait a carriage was secured at double the regular fare. When we got to the end of our wheel journey, one of the ponies was missing, so we had to start a "ride and tie." Dark fell upon us in the densest jungle I have ever seen. It was pitchy black, and there were sounds in the jungle all round us. Pigs were strongly in evidence,

and their musty smell was with us for furlongs at a time. At last we reached our destination, and were glad indeed to get a long drink.

The coffee in East Java is wonderful. As in other countries, there are failures; but the successes are marvellous beyond description. All the coffee is grown under deep shade; and where the soil has any inclination to stiffness, it is constantly worked up with shangkol. The young coffee is very forward; but perhaps figures of actual results will be more interesting than the most glowing descriptions of appearance. One estate that I went over gives the following returns:—Total area 450 bouwas. Age of coffee 12 years old to 2½ years old. All expenses, including the cost of the young coffee not yet in bearing, are paid; and the coffee has further given a clear profit of two hundred and fifty thousand rupees over and above the capital invested. Ye gods and little fishes! Let us pray that the Malay Peninsula may erupt heavily. The old saying is, "It's money that makes the mare to go." I am sure that it's volcanic action that makes the coffee to grow.

I am more or less sensitive about being called an Ananias; so I give the following figures taken from a Dutch Directory. The results are extraordinary, but I simply tell the tale as it was told to me. The appended table will, I am sure, be of interest to many a planter:—

Estate.	Elevation.	Bouwas.	Crop in Pikuls.						
			1884	'85	'86	'87	'88	'89	
Limburg	1,200	600	1705	500	2041	5342	6170	5700	1200
Ayer Dingin	3,500	503	3200	3200	5250	3019	4637	3145	3671
Pangadjaram	2,500	462	2100	2420	4560	1984	7970	5550	2000
Minjin	3,000	560	1600	3108	4150	1686	5620	582	6331
Monorarie	3,500	650	3800	4300	1500	3900	2430	2200	1000
Karang Nongko	500	315	...	380	6000	2100	5000	4000	2000
Kati Manis	2,000	550	6000	3350	6000	1000	3000	3100	530

Let any practical planter work out these figures, and he will find a very healthy average at the end of them. The estimate for Limburg this year is 11,000 pikuls; and there is every reason to expect that it will be realised.

I have seen no poor soil. All is very rich, and of volcanic formation. The strongest complaint that I heard was that there was too much ash in it. Considering that the analysis of the coffee bean shows over 60 per cent. of potash, ash must be deemed abundant to be a source of complaint!

The hospitality of East Java is unbounded. Horses, carriages—everything in fact is put at your disposal, and the merest stranger treats his visitors right royally. Another man and myself went to an estate the manager of which was unknown to us. We introduced ourselves and asked to be allowed to see his coffee. He took us over the whole himself, and then after liquoring us up and asking us to stick up a cigar seegar obstaken) he insisted on lending us his carriage to go on with, as we should find it inconveniently hot to go on riding.

The Java system of cultivation is thus: they work the soil, not the bush. But little is done to the bushes after topping, except taking off the suckers but the soil is kept constantly worked up and open. Very little manuring is done: in fact one planter said to me "If my coffee needed manure I should abandon it at once." I went over one estate that had just given 10 piculs per bouwa. The coffee looked well and in good heart, and able to be the same next year.

With results such as I have given it is not surprising that there should have been a heavy rush after coffee lands lately, and almost all available land has been taken up. A friend of mine has just got a concession of 7,500 bouwas, and this I believe is practically the last land to be got in East Java. I hear however that the Assistant Resident of Bawean is rather sore about the rush on East Java, asserting that he has better lands on his island, which being thickly populated, offers a sure supply of cheap labour. Bawean is in regular communication with Java, and is only 8 or 10 hours' steam from Soerabaya.

The climate of the hills is delightful; cool and bracing: and I think that if Singaporeans realised that such a delightful little sanatorium as Prigin could be reached at such a cheap cost, mere would avail themselves of it.

I also heard much of a sanatorium at Tesari, 6,000 ft. elevation, but had no time to sample it myself.

The country swarms with game. A few days ago a planter shot three tigers three nights running. You can scarcely go a hundred yards without finding pig-track; and there is other game in abundance.

Anybody contemplating the trip direct to Soerabaya should go by S. S. "Bawean." She is clean and comfortable with good food, a first rate Captain, artist, musician, raconteur, and general good fellow.

I have omitted one thing which struck me especially, and that was the extraordinary readiness of the Javanese to give you their figures. If you say "By Jove! that sounds healthy." The reply is "Well, here you are; you can copy the figures if you like" and out come the books. One man was so kind as to have his account, which were in Dutch, copied out in English for me. During my trip I came in contact with Scotch, English, Dutch and German; and upon my word it is hard to say which showed the greatest kindness to a stranger in a strange land.

A young Englishman caught a boa-constructor a few days ago. He was out with two coolies, when he saw the snake, and immediately rushed and seized it by the tail, calling on his coolies to do the same. They pluckily did so: but the great brute dragged them all along after it. Seeing it was hopeless to capture it thus, the master told his men to hang on to the tail while he ran swiftly along the body and collared it by the neck. After a fierce struggle they ceased it and got it home, and caged it securely. Being at the bungalow shortly afterwards I asked to see the snake. "Oh certainly" said my host; "but he will be in the water now; however, I daresay I can stir him up. The beast was 30 feet in length. The same young gentleman had unexpected visitors some time ago, and as is not unusual in the jungle the larder was empty; however he managed to put on the table some very good steak which, after they had enjoyed it thoroughly, he informed them was monkey-flesh." They were horrified and disgusted; however they called on him on their return journey a few days afterwards, when in a loud voice he called out to his boy to "Kill a monkey." His guests smote to each other. In due courseiffin arrived. First came soup—and then the steak. The guests to each other wink an evil wink, and handed their steaks to the dogs. The host meanwhile ate calmly on, being much flattered by his friends about eating that "beastly monkey flesh." When he had quite finished, he lay calmly back in his chair and said "Well, do you know, I think I have scored off you fellows again: the meat which I ate and which you gave to the dogs was good beef-steak; but the soup which you seemed so to enjoy was monkey-soup."

Before I close these jottings I must sound a note of warning. Let no aspiring young planter wishing to

better himself, or out of a berth, say to himself "Here is a paradise for a coffee planter, I will go and try for a billet." Unless a man knows Dutch language and customs and at least one dialect of Javanese, he will have to begin at the foot of the ladder on a salary of something like sixty rупes a month. Preference is also given to a man who has lived for a time either in Holland itself; or in Netherlands Indies. The etiquette in Dutch officialdom is somewhat complex: and a planter is frequently brought into contact with the officials both in regard to his land and other taxes, his labour, and in many cases his water-supply. These dealings require much tact and "a deal o' salutin." Do you know that story? Well, here it is. In a certain British colony a few years ago war a Padró who used to ride 40 miles to take three services every Sunday, and the planters in each district used to help him by reading the lessons for him. On one occasion it fell to the lot of a good man, but somewhat rough in the cut, to read XVI Romans. He got through the first two verses when he stopped and said audibly "Humph! There's a deal o' salutin here!" Glancing down and seeing that all the chapter was more or less of the same description, he read the last verse only, when he shut up his book with a bang saying "Here endeth the Second Lesson."

Here also end I.—*Singapore Free Press.*

LETTERS FROM BRAZIL.

LAWLESSNESS AT S. JOSÉ—CLIMATE AND CONDITION OF THE COUNTRY TO THE SOUTH OF THE STATE OF MINAS GERAES—RAILWAYS—LABOUR QUESTION—DRAW-BACKS TO EUROPEAN IMMIGRATION—COFFEE CULTIVATION—WANT OF SCHOOLS FOR EDUCATION OF CHILDREN—THE "MINEIROS"—HALF-CASTE LABOURERS ON COFFEE ESTATES—MARRIAGE LAWS—RESULTS OF THE ABOLITION OF SLAVERY—THE LATE REVOLUTION—HOSPITALITY OF THE PEOPLE OF THE ESTADO MINAS—GAME AND SPORT—AN ITALIAN COLONY—NOTES BY THE WAY.

I think my chronicles were brought up to our arrival at the "Travellers' Retreat" at Guaxupé at José. We got very bad accounts of the lawlessness of the people in those parts and Ananias told that a man had been murdered in the open street a few days before, and that was the latest news he had got from that quarter. We were now snugly lodged in the "Travellers' Retreat" in this same village, and we found the people of the place quite tame, and not at all a disorderly lot. However, on enquiry we found that the headman of a troop of pack-mules had been coolly put to death by a band of some six or seven persons under the orders of the local justice of peace. A warrant had been issued to imprison one of the mule drivers, he was not found among his companions when the justice went to serve the warrant, and on the plea that the head-trooper had let the man who was "wanted" escape, with very little ceremony the gang at the order of the Magistrate "despatched" the same head-trooper with ever so many cuts with the sharp-pointed knives which all the male population carry openly in every part of Brazil. In justice to the administration of the law, however, we must add that the most of the fellows were captured, but the justice of peace was allowed to hide amongst his friends. While waiting for trial the whole of the prisoners escaped out of jail, and nothing more was heard of the case up to the time I left these quarters.

During the time my commission lasted, I travelled over the most part of the south of the State of Minas Geraes. A finer climate one could scarcely imagine. The elevation is from 2,000 to 2,500 feet above sea-level. The temperature is seldom above 88° Fahr. even at the hottest time of the year and the nights are always cool. The country is hilly, the hills being covered with virgin forest, except on the parts which are planted with coffee. Coffee is subject to damage from frost, in the hollows, but on these cane and cotton can be

grown luxuriantly. Tobacco is largely grown, both for consumption in the country and for export. A large part of the land is in campo, or common grass land. The grass is of a coarse common kind, with little feeding qualities in it, but many farmers are planting the sweet grass called "capim melada," and where this has once got a good hold on any patch of ground, it spreads with amazing rapidity, and soon becomes almost a pest. It being something of the nature of your Mauritius grass, its roots spread rapidly. It seeds once a year, the seed being light, it is carried by the wind to many abandoned clearings and uncultivated pieces of land. I am sure it would grow well in your Ceylon patanas, and if land leeches would allow of the practicability of sending cattle and horses to graze, it might be of value to your country. This reminds me that I long ago promised to procure seed for Mr. Whyte of Nuwara Eliya.

The rains here fall regularly, being heaviest and most frequent in September, October, November, and February, March and April. I should say the rainfall would be equal to that of the Province of São Paulo, say 80 inches a year.

The soil is of a chocolate colour, and not considered equal to the *Terra-rocha* of São Paulo; but coffee comes quickly into bearing and continues to give heavy crops for six or eight years, when it falls off a little. On *Terra-rocha* on the contrary, coffee estates are often spoken of as forty years old, and bearing equal to young coffee. What one observes all along the south of Minas, and which they are very scarce of in São Paulo is the abundance of water for driving machinery. This is owing to so many well wooded hills.

Railways are being projected all over these parts, indeed all over the interior of Brazil; and if the finances of the country hold out, of which many are doubtful, transport will by-and-by be made easy. The capital for the making of these Railways has to be found in the country. Some consideration ought to be given to the fact that while they expend so much on these useful works they will have less left to spend on what is really urgent, the supply of labour for agriculture, and which, by-and-by, will be the great burning question in Brazil.

The south of Minas would do well for European immigration, but, there are difficulties in turning it to good account on small farms. Capital amongst small farmers is scarce, and there is a great deficiency of means for furnishing the three indispensable necessities in starting an European colony on a coffee estate, namely, *tile-covered houses, well enclosed pastures for cows, and cash to advance the colonist for nine months or a year, for domestic needs, until he can procure food from his own patch of ground, so that these necessary conditions can only be implemented by wealthy Fazendairos.* One finds here, and there small colonies located on coffee estates, and these are doing equally well compared with others in the wealthy Province of São Paulo. Whatever may be said against European emigration to Brazil,—by agitators in some of the countries which supply the immigrants—the agricultural labourer in the coffee-growing districts of Brazil is much better off than he was in Europe, and he has a prospect at no distant date after his arrival, of becoming a land-owner himself. The only draw back I see to the system, which one may say is now past the experimental stage, is the want of schools for the education of the colonists' children. On large farms the owner supplies a school-master, but the small farmer cannot afford it, and although the Government is very liberal in giving free education where a certain number of scholars can be guaranteed, and schools for primary education are established in all populous centres, many of the small farms are scattered, and at far distances from those schools, and what with the occasional heavy rains, incurring danger to the little ones in crossing swollen streams, and the need of the children remaining pretty often at home to help in the harvesting of the various crops, educational advantages cannot be much availed of.

As the country gets populated there will be improvement in this.

The "Mioeiros," as those belonging to Minas are called, are a very happy and contented lot of people; they supply nearly all their own domestic wants, not only as regards food, but also clothing. On every farm there are rude appliances for turning cotton and wool into cloth, and it is made of different thicknesses from fine calico to thick counterpanes. Trousers' stuffs made in Minas on the farms are in great demand in other parts of Brazil. They are strong and the colours are fast. Troopers from the interior take often large quantities of these to the Province of S. Paulo for sale. The manipulation and manufacture of these textile fabrics generally devolves on the female portion of the establishment. The lady of the house takes charge of the women and children, from whom she exacts a fair amount of work between seven and ten o'clock at night. I fear that now that forced labour is abolished and railways are bringing European goods that will prove a substitute, this interesting industry will be neglected.

I mentioned before that slavery had not such a stronghold in these parts as in some others, but there are many half-castes between Portuguese and Indian, who work in gangs on the large coffee estates. The condition of these is being very much improved by their being allowed to build a house for themselves, and plant a piece of ground with provisions. Formerly marriage amongst this class was of rare occurrence, but families were reared all the same and couples lived happily together during their lives. The blame for this want of regard for the nuptial ceremony must be laid at the door of the church, for so many confessions and preparatory catechizings had to be gone through, for weeks before the marriage could take place, people evaded it. Civil marriage had been for some time in the programme of advanced liberals, and the republican Government at once declared for it, and made civil marriage the only one recognisable, by law and have also made it a crime punishable by fine and imprisonment for any priest to celebrate a religious marriage before he has assured himself that the civil has been properly, that is to say legally, performed. The custom after that decree has been to marry civilly, to make it legal, and those who want to keep right with the church are afterwards married spiritually. This will ameliorate considerably the moral state of the class I am now referring to. The improvement in this respect will also extend to the class who were formerly slaves, for the law of 1871, while prohibiting the sale of any one member a family, away from the other members, lost this salutary effect as regards the slave, if the father and mother were not married. The consequence was that, as a slave could not marry without his master's consent, and the master allowing him to marry depreciated the slave's market value, the rule was for masters to forbid marriages.

Many snug little homes have sprung up on the estates since the emancipation law of May 13th, 1888, which abolished slavery for ever in Brazil, was passed; and many dark-coloured couples, to whom the master, before, or the priest later on, denied this civilized right are being by the civil law made man and wife and their chubby children are legitimized. While referring to these "libertes" as they are now called, I must mention that the effect of abolition has not been so disastrous to agriculture as many predicted. A great many have left the old plantations, but are working on some other, and are very orderly. They prefer to work on piece work by themselves rather than the old system in large gangs, reminding them of the time when they were driven like oxen or mules by a man with a whip behind them. Last year there was not much coffee lost owing to the blacks not working. The change has been most felt in the household establishments, indeed it has upset domestic arrangements terribly. Formerly the house used to be full of negro and mulata women and girls, over whom the mistress of the house used to rule with rigorous exactitude, and whether it was owing to the peculiar temper of the lady or the wilful obstinacy of the female captive a great many authorities agree in saying, that punishment was more severely dealt out to poor unfortunates inside, than on those outside the

house. The instrument of torture was not a whip but a "palmatorio," a piece of wood shaped like a flat spoon with a few small holes bored in it: this was applied to the palm of the hand; one poor innocent was told off to apply it to the offender. I am inclined to think stories like these have been much exaggerated for no case of such treatment has passed under my observation: on the contrary I have known many kind and considerable Brazilian ladies, who gave much indulgence to the females under their charge, and I do not wish to join in this libel against the Brazilian fair sex. At the same time on visiting Fazendeiros' houses at the present time there are many excuses made for want of better treatment to a visitor in the form of having so few servants now, to do particular work. In many instances the mistress of the house or the daughters will bring the usual cup of black coffee, which everyone gives to a visitor here, be the visitor or the householder ever so humble.

It is natural to suppose that the coloured house-servant girls sighed for a home of their own, and many of them left to marry those who had been refused to them before. A great many were trained to do first-class needle-work and lady's-maid work, and all could do laundry work, and cooking, and in the towns both before emancipation and since there was need is always a large demand for those who can hire themselves out for such useful work.

The natural inclination of the coloured servant girl seems to be to get married to one of her own race and colour, and they seem to make their homes cheerful and comfortable after marrying. Those who thought that the members of the coloured races after emancipation would gradually allow themselves to sink into social vices and degradations have been woefully mistaken. They certainly, both sexes of them, spend a great deal in outward adornment, and in the exercise of this the taste often leads towards the gaudy and ridiculous, but this is the nature of the African race.

Our housewives here will gradually settle down to do without the coloured servant, and be contented with the Italian, Portuguese and German maids; and when the mistresses come to get acquainted with the treatment of white girls, things will get again into some sort of order in the old homes of the coffee and cane planters.

During my sojourn in these parts the so-called Revolution came off. Dom Pedro II. was quietly sent away to Europe and the army and navy took his place of power, appointing a provisional Government of Ministers amongst people well-known beforehand for their republican sympathies. In the interior the news was received with perfect indifference.

The leading republicans in the various districts were the first to move in the matter of receiving authentic news and propagating it. The constituted authorities remained still and allowed the others to do as they liked and soon came appointments by the central Government of new municipal councillors etc. to substitute the old, and regularly elected municipal councillors had to retire before the Government nominations, and these selections were made by the central authority for all appointments from the presidents of the provinces down to the postmaster of the smallest village.

Poor people who could not read newspapers got the news from those who could read. It was not considered fashionable nor was it safe to oppose these holding Government views, and those in humble condition were made to believe that this new republican form was essentially a poor man's Government.

As far as my observation went, the deposed Emperor had a great deal of sympathy from among the lower classes. They never could find out what evil he had done, but they all remembered of his being often publicly extolled for great and good actions.

I need not go a second time into the causes that led to this. I may repeat that they were various, but the principal one was that many great military and naval officers thought themselves slighted, and gradually got the two services to promise to take part in the change, and thus it was effected—without bloodshed—for could there be any when all the people who had arms were in favour of the change?

The great Emperor was now banished the country. He who scarcely a year before—when on his return from Europe in improved health—was received in Rio de Janeiro in a manner quite surpassing the reception, in European capitals, given to the greatest heroes of modern times. Triumphal arches were placed in all the principal streets. Life-size portraits in oil of him and the Empress adorned the fronts of many commercial buildings. Rose leaves covered the ground wherever he set his foot. Deputations from all associations, guilds, societies and clubs gave congratulations. The populace half-mad with excitement and frenzy, roared the air with their boisterous acclaim. Bells rang from all the church spires, cannon salutes shook the city. Fireworks of all descriptions were let off, even during daylight, and at night the city was publicly illuminated, and windows were hung with Chinese lanterns, and coloured-glass devices. Next day the newspapers and telegraph-lines carried the news to the interior, and a milar rejoicing took place in all the principal populated centres throughout the vast Empire. Could ever a monarch be more popular than Dom Pedro Segundo? But what a change was in the near future!

A few months passed during which the country was most prosperous, household necessities were much reduced in price, and exchange had risen higher than ever it was known before—the milreis was above par, which is twenty-seven pence, and for over two months it was $28\frac{1}{2}$ pence, and the minimum during 1889 was $26\frac{1}{2}$. European capitalists were sending large sums into the country for investment such as loans to railway and other public companies, slavery was a thing of the past, everything showed that an era of prosperity and contentment had dawned in this new country, and the Government to all appearance was a popular one. The unexpected always happens. About the beginning of November 1889, whispers began to be heard by some, who were half afraid to repeat them, about the disquiet in the two services and on the 15th of the same month the army were all paraded in one of the large squares of the city and the Republic proclaimed. The Navy also joining, people saw that any opposition could be put down by force. Thus happened the bloodless revolution. The Emperor was told to depart for Europe, a steamer being at once chartered for him. The Prime Minister, his relations and some of the supporters of the deposed Government were banished the country.

The republican form of Government had existed for some five months when I returned from the wild west. My return to Rio de Janeiro had to be by the Province of São Paulo. Civilized life was met with first in the town of Mococa, for in the interval since I left Rio the branch of the Mogyana had been opened to that town. Some fine fresh looking coffee estates were passed through before Mococa was reached, and most of them with small villages of houses for colonists, but most of the colonists were nationals, that is to say half-breeds between Indian and Portuguese.

I can not leave the Estado of Minas without noticing and noting the hospitality, which these simple although many people deal out to strangers. However small the farm may be, if you call at it, you have what they can give you with good-will. There is food supplied in abundance for man and beast and if you arrive about "Ave Maria" time you are given supper and a bed and your animals are well cared for. I have lively recollections of the jugsful of milk drawn from the cow in the morning, as soon as one got out of bed, and if you expressed a wish the night before to start at daylight, the animals were always ready. In some parts winged game was plentiful, and if the day promised to be cool, cloudy, I would spend a day shooting snipe, wild duck, and a sort of grouse they call partridge ("perdic"). Deer is plentiful, as also wild-har, but it requires some days to get up a pack of dogs, and a party of huntsmen. The Mineiros are a kind, contented, brave and patriotic people;

I spent a day and a night at Mococa, a rising town of some 3,000 inhabitants mostly Italian. More than half of the town seems not more than a year old.

A small river runs through the middle of it, and the ground rises on each side of the river at a slope of about one in fifteen. The stream runs towards the west, the public buildings, such as churches, the municipal chamber, court-house, jail, &c. are on the left bank on elevated ground. The railway station is on the right or north side, also on high ground, and near it is a comfortable hotel kept by one Julio dos Santos. The hotel was full of railway engineers, contractors, and the usual complement of "comots."

I enjoyed very much the short time I stayed there, and made a few friends, who pressed me to stay a few days, and if I had known beforehand that I could not get my own favorite mule on the same train along with me I might have accepted some of the invitations. I had despatched my attendants to their homes, had packed up for Ribeirão Preto, had written to a friend to expect me there on a certain day, so I had good-bye to Mococa.

The train starts at 6 o'clock; the line is a new one and trains have to move slowly, and for those special timetables are arranged and calculation is made for accidental delays, but it is seldom that the train arrives at the junction with the main line after the express has passed.

At São José do Rio Pardo our old friend Ananias was on the platform: from him I had a cup of black coffee. I also noticed that the kangaroo horse and the one horse trolly were in the station yard. Ananias was quite bright, he had realized the dream of his life. Brazil was now a Republic, and he liked to be reminded that he had prophesied the near advent of it, when I passed up this way some six months ago. São José had increased in size; the Republican Municipality were to pave the streets, colonists were flowing fast into the district, the crop which was nearly all despatched was a large one, and amongst the late unruly citizens of São José all was contentment.

Casabraca was reached about 9-30 a. m. I knew I had to wait here until 3 p. m. for the express from S. Paulo to take me on to the town of Ribeirão Preto.

Having made the acquaintance of an engineer in the interior the members of whose family were located in Casabraca and who was now on a visit to them, to fulfil a promise I made some time before, I went to breakfast to their house, where I was kindly entertained until the afternoon. From Casabraca passing by the important town of São Simon there are many very fine coffee estates. The railway passes right through the Fazenda of Santa Veridiana, the property of Conselheiro Antonio Paço, which I gave some particulars of in my last. The heat had been suffocating for the most of the day, but at 4 o'clock came on a heavy thunderstorm, and rain continued to fall the rest of the evening. It was quite dark before the train arrived at Cravinhos. This is a small town next station to Ribeirão Preto, and completely surrounded by valuable coffee plantations, which I could not see until my return.

It was past seven when Ribeirão Preto was reached; the rain had ceased for a short interval, and the town was well lighted, not as yet with gas, but with kerosene; so there was no difficulty in reaching the hotel with my friend who was expecting me.

Here I was to spend fifteen days, and include in these the Holy Week, which here, as in all parts of Brazil indeed in all countries where the Roman Catholic is the only religion believed in, is a very important season of the year. My visits to some important coffee plantations I must leave for the second part of this letter.

A. SCOTT BLACKLAW.

COFFEE DRINKERS.—The following curious calculation has been made:—The Dutchman drinks on an average $16\frac{1}{2}$ lb. of coffee per year; the Belgian about half that quantity; the Norwegian about $6\frac{1}{2}$ lb; the German about $4\frac{1}{2}$ lb. per head, being about 2 lb. more than the Frenchman, who has the reputation of being a great coffee drinker, whereas, according to statistics lately taken, the Englishman consumes only $\frac{1}{2}$ lb. a year, and the Russian only 1-5th lb.—*English Mechanic*.

PLANTING PROGRESS IN WEST HAPUTALE, CEYLON.

We have the following news of a little known district which is yet to hold up its head with tea and railway communication close by. Our correspondent writes:—

"A considerable change has taken place in the Kalnapahana Valley within the last 18 months. Mr. Mayow has about 100 acres in tea on Bray estate; Mr. Orclard has a fair acreage now on Udaveria, and has just sold a half share to Mr. F. Bateson of Broughton. Mr. Mills (West Haputale) has the largest acreage; but I am not sure what it is. He also has a factory; Mr. Anderson on Moneracenne too has some acreage in tea. Our tea is giving us at the rate of 400 lb. of made tea an acre, and as our land was good virgin soil bought from Government at about R40 per acre, we may reasonably expect a better yield still when our trees are older. Most of us went in at first for clenchua officialis (our elevation being high) which soon died out! One good thing about it was it took little or nothing out of the soil! There is wind in the Valley, but we find we can "doidge" it very successfully with belts. The Ohiya Valley, where there is to be a railway station (or siding), is quite close to the Kalnapahana Valley, and we hope Government will cut a road for us which will not be an expensive one."

VARIED USES OF RHEA OR RAMIE.—We were lately surprised to learn that rhea was a good food for silkworms. Now we are told that "steam pipes are now made of ramie fibre, and the material is pressed so closely together by means of hydraulic machinery, that it has a tensile strength two and one-half times that of steel"

COFFEE IN BRAZIL.—The *Journal do Commercio* published on the 6th a letter estimating the Rio and Santos coffee crops at 4,000,000 bags each. The writer says that this coffee will be sold for over 1,000,000,000 francs or 350,000,000\$ in gold, equivalent to 560,000,000\$ in paper money at its present value. —*Rio News.*

GEMMING IN RAKWANA.—Mr. Baddeley, the gemming expert from Ratoapura left today (16th.) for Europe in the "Myrmion" his services being no longer required in connection with gemming operations in Rakwana. Mr. Baddeley confirms what our Rakwana correspondent reported—namely, that the pits are being all closed there, good stones not being forthcoming. And yet good stones are on sale each week in Colombo. Where do they come from and how are they obtained? Until this question is settled and proper steps are taken to prevent theft at the gem-pits, it need not be expected that gemming will be found a profitable enterprise for Europeans in Ceylon.—*Local "Times."*

A PLANTER ON TOUR.—Mr. W. G. Sandison, of teneased fame, is down in Colombo again, awaiting the "Salazio" which is to convey him to Java, where he means to spend about six weeks and then return to the island. Mr. Sandison is essentially a peripatetic planter, and is continually on his travels. He has been to Java before, on which occasion, he says, he went on pleasure, and he adds that "Ceylon chappies may take the hint that Java is the place to go to enjoy oneself;" but this time, as we stated recently, he proceeds there on business. When he returns, he says, he means to go to Madagascar, but he has not made up his mind yet as to whether he will proceed there direct or visit the "old country" first. Most likely he will do the latter, for, though he has passed over a quarter of a century in travel, chiefly in the East, he keeps up the love for his home in Scotland, which he visits often, and his judgment of whether a thing is good or bad depends very greatly on whether it comes from near Inverness or far from it. It is not generally known that Mr. Sandison was formerly in the Manipur district, near the scene of the recent rising. He was, however, engaged there in planting, and came within an ace of getting killed by the natives just before he left.—*Ibid.*

CEYLON is marching on! Even if the rubber crop is not yet what was expected, the colony is doing well in other things, and it will supply rubber in time. It is agitating now for an exhibition, not of its own products only, but a cosmopolitan affair, at which all nations may show the goods they want to sell in the tropics.—*Indianrubber Journal*, June 8th.

THE DEATH-DEALING AMAZON.—Wooden crosses, marking the graves of immigrants, are as plentiful as the rubber trees on the banks of one or two Amazon tributaries. The Purus river district has only a population of 16,000, instead of the 40,000 which we might expect from the immigration that has taken place.—*Ibid.*

"BERMUDA IN MAY."—Such is the title of an exceedingly graphic and interesting description of the group of coral islands about twenty miles square, which, like the Bahamas, are largely resorted to by Americans who seek change. This account appears in *Garden and Forest*, a valuable American publication, whence we shall transfer it to the *Tropical Agriculturist*. Apart from the indigenous cedar and the introduced elder tree of Britain much of the leading vegetation is such as prevails in Ceylon.

RICE CULTIVATION IN THE UNITED STATES.—An elaborate article on this subject, illustrated by engravings, principally from quaint Burmese drawings, appears in the *Louisiana Planter and Sugar Manufacturer*. After a sketch of the history of rice culture and the kinds used and modes of cultivation in Egypt, China, India, Burmah, Ceylon &c. The whole process of growth and "manufacture" in the United States is described at great length. We have marked the article for the *Tropical Agriculturist*, because hints useful in Ceylon may be obtained from the widely different mode of culture observed in the Western land whither rice seems to have come from Madagascar. In slavery time the enterprise was of great importance, but it was ruined in the Civil War and the writer of the paper is not hopeful of its revival to any great extent by means of expensive free labour. We have hill rice and irrigated rice in Ceylon; in Carolina the grain is amphibious,—grown in water, but ripened on dry soil.

TEA.—A writer on "Etiquette" in a contemporary emphatically observes, "It is not usual to offer a second cup at afternoon tea. . . . it is not as if tea were a meal." Let us hope (writes "Miranda" in the *Lady's Pictorial*) few people will be so inhospitable as to be guided by this churlish view of the meagrier supplied teapot. Talking is thirsty and fatiguing work, especially when combined with the pretty behaviour necessary where one's hostess is a smart acquaintance rather than the familiar friend whom one would have no scruple in asking to replenish one's cup, and it is an odd way of welcoming guests, indeed, to limit them to half the refreshment they would have had at home, though judicious, no doubt, when a repetition of the visit is not desired. "They always gives such a nice tea," is a remark one frequently hears made with much appreciation, and people hardly realise, perhaps, how much the popularity of their "day" depends on the comfort of this little meal—for meal it must certainly be accounted, considering the lateness of dinners. Partially warmed cakes, served on a cold plate with little islands of half-melted butter on them, stale biscuits, bitter, over-drawn tea, or tepid "water bewitched," will dishearten the most cheerful guest, yet such experiences are by no means uncommon in making afternoon calls.

PROMISING INDUSTRIES FOR JAMAICA.

VALUABLE LECTURE BY MR. MORRIS.

Not long ago Mr. D. Morris, assistant Director at Kew Gardens, England, delivered a lecture under the auspices of the Kingston Horticultural Society, in the Exhibition Hall. There was a large attendance, and among those present were His Excellency the Governor, Lady Blake, the hon. Dr. Philippo President of the society, the hon. S. C. Burko, the Committee and Officers of the Kingston Horticultural Society and many ladies. The platform was decorated by the Botanical Department in a most tasteful manner with numerous plants and flowers, among which were the *Canna* or Indian shot, (sent by Mr. Bowrey) some beautiful *Eucharis* lilies (sent by Mr. T. Oughton) and specimens of the coffee, cocoa, nutmeg, and co'a plants, while on the table were a fine collection of tomatoes, sent by Mr. Bowrey and a basket of green peas sent by Col. White Oaklands. There were also samples of sisal hemp, bow string hemp, manila hemp and china grass.

Mr. Morris, who was received with applause said:—The lime is a small acid fruit which can be used in more ways than you, I am sure, are aware of. It can be planted between the banana trees at 16 or 18 feet apart and it springs into a small tree when it is 10 or 12 inches high. Where the bananas are exhausted then the limes are ready to be reaped for the first crop. The latter then can be used in many ways. They can be shipped raw, in barrels to Boston or other towns where they are used in that condition. The raw juice can also be shipped to England or the States. The raw juice is concentrated; being holed down in large quantities until it is reduced to one twelfth of the original volume. It then turns of a black color and is called concentrated lime juice. It is sent home for the preparation of citric acid which is in much demand by the large factories of Yorkshire and Lancashire. In the centres of the lime industry, women sit in the plantations with brass basins in their hands in which by a simple process they bruise the rind of the lime from which a fine delicate acid exudes. At the end of the day the woman or girl gets paid 6d., 8d. or 9d. for the quantity she has obtained during the day. It is then filtered into a large bottle carefully stoppered, and sent home. This is the essence of oil of limes for which there is a large demand. I can assure you that there is a wide and profitable field for anyone starting the cultivation of limes in this island.

I now come to the cocoa or chocolate industry. Some years ago we thought the chocolate industry had almost died out in Jamaica. It had been so neglected that except in some few places no cocoa trees were left. Then the endeavour was made to revive the industry. There is not the slightest difficulty in establishing a cocoa estate, you have already got your banana shading; all that is left to do is to raise the plants and put them under the shade of the bananas. The cocoa trees only require to be carefully planted and pruned—young plants like the one here should be very carefully pruned indeed—all the shoots should be removed and the trees encouraged to send out their female branches so that the pods borne on the stem of the plant may have plenty of light and air. The trouble here is in preparing the produce. I am sorry to say that out of 30 samples in the Exhibition there are not more than four or five that are good. Good cocoa properly cured sent from

Jamaica would fetch 70/. it now fetches only 50 to 60/—a loss of 10/ to 20/ solely due to the curing.

When the pods are broken and the beans taken out they should be fermented in such a way as to produce a change in the beans; instead of being bitter and adhering to the beans the skins should readily come off, I appeal to those interested to try and do something to remedy these things. Jamaica cocoa is at the bottom of the list of cocoa in the London market; you lose 10s. per cwt. on account of bad cocoa. It is not reasonable that the people of Jamaica should throw away a sum equal to about £20,000 or £30,000 a year because they will not cure their cocoa properly. It is not because they do not know, for from the number of pamphlets that have been issued and information given by myself and Mr. Fawcett it should be well known. There are two points with regard to the cocoa industry that may possibly assist to do good; first it would be very desirable that some one acquainted with the black people should go among them and talk to them and explain to them exactly what should be done to cure the cocoa properly; then the merchants of Kingston should not buy the half ripe, badly cured cocoa which is being shipped in such a way as to bring discredit on the island. The matter is in the hands of the merchants, they should refuse to buy the cocoa that is dried in the sun and allowed to become covered with dust and dirt. Those who ship it home and call it Jamaica cocoa are doing a bad turn to Jamaica. If they would offer a better price to the grower for good cocoa they would find the men willing to cure it as they ought. I do not think Jamaica deserves to be at the bottom of the list in anything. Blue Mountain coffee is at the head of the list; pimento is unique, your sugar there is nothing to be said against and with regard to cocoa I think it is your duty to raise it above its present value and condition. I may say that the cocoa of Trinidad, Grenada, Dominica and other parts of the world are all taking rank above the cocoa of Jamaica. Grenada cocoa is not of the best kind, they have not got as good sorts as you have, but seem to take greater care in curing and they get better prices than you, and near the prices in Trinidad. In Ceylon they took to preparing cocoa and although lately they have many enemies to contend against, their cocoa at the present time gets 110/ to 120/ per cwt. The other day a planter in Montserrat cured it in the Ceylon way and got 90/ per cwt. That shows in regard to cocoa that it is purely a matter of curing it.—*Jamaica Gleaner.*

PLANTING IN THE NORTH-CENTRAL

PROVINCE:

COTTON—COCONUT—PALMYRAH.

The first Provincial Report for last year has reached us from Government this afternoon, being Mr. Ievers' for the North Central Province. We can do no more today than say that Mr. Ievers is a firm believer in the future of his Province with its restored irrigation works and thousand village tanks. But that is in the Nuwarakalawiya division; Mr. Ievers is now anxious that something should be done for the Tammanukunwa district, and he sketches a road (already partly voted for), head-works on streams and sluices for tanks. Mr. Ievers considers Nuwarakalawiya "the best-roads district in the island," and yet Mr.

Christie, M. L. O. in his condemnation of irrigation said that a network of roads was necessary. Here are some interesting paragraphs:—

Cotton Cultivation.—This industry may be said to have been a complete failure. The seed was supplied in the previous year, and although the plants promised well up to a certain stage, so much damage was done by the drought that the crop was not worth the transport.

Palmyrah.—Mr. C. A. Murray had these plants put in along several miles of the Yoda-ela, and I found that the majority of them were doing well, although they have not been specially cared for or fenced. I hope to procure a large supply in 1891 to extend this cultivation.

Coconuts.—One of the great advantages which "irrigation" has secured for this Province is that coconut cultivation is rapidly extending. To any one sceptical of this statement I would recommend a visit to the villages below the Yoda-ela, or to take Karenbawa, in Kalagam korale, as a specimen. I am having a census taken of coconut trees, village by village, which will show hereafter whether the cultivation is extending or not.

Indian Corn.—This valuable grain is largely grown in oheas; and that which is produced in Tamian-kadawa will compare favourably with the finest Russian-grown corn I have seen. But its value is much lost from the unhealthy manner in which it is eaten. The pods are half-boiled and then gnawed off. This mode of "cooking" is said to be productive of several evils, as may readily be conceived.

THE LEAVES of *Salvia triloba* are extensively used in the Levant in the preparation of a kind of tea. The plants are simply cut, dried, tied in bundles and sold on the market-place, and are found, ready for use, in every café of Greece, and even in the poorest homes. This "Athenian tea," or as the Greeks call it, "Phaskomyia tea," is believed to be a sure preventive of colds and fevers, and is therefore universally drunk in winter weather and by sailors at sea.—*Garden and Forest.*

GOLD IN SIBERIA.—From a paper in the *London Times* we quote as follows:—

Of all the industries of Eastern Siberia, probably the most important is the gold mining industry. The richest washings and mines are those of Yeneseisk and Olekminsk, but the yield of metal at these places, owing to the present primitive and wasteful method of extracting it, is not nearly so large as it might be. Mining engineers calculate that when the railway is constructed and it is possible to transport hydraulic gold-washing machinery they will be able to save at from 25 per cent to 80 per cent of the gold which is now wasted. When these improved methods of extracting the metal have been adopted, they are confident that the yield will be about double what it now is. At present, owing to the immense distance of the washings of Eastern Siberia from Russia, it is not considered profitable to work "washings" unless they produce five times as much gold as the least profitable of the washings in the Urals. It is easy to see, then, that the railway will give an immense impetus to the gold mining industries of Eastern Siberia. A regular gold fever may, indeed, be expected to set in. Few people have any idea of the amount of gold which has been obtained already from Eastern and Central Siberia. * * * Eastern and Central Siberia has alone given to Russia, during the past 51 years, about £120,000,000 worth of gold. The Ural and Western Siberia have, I am told, furnished an even greater quantity. And, when it is remembered that the yield of gold would be much larger—some say twice as large—if proper mining machinery were in use, and that much of the gold which is extracted never finds its way to Russia, but is surreptitiously disposed of to the Chinese and private traders, no one will be surprised that the Government are anxious to keep a firm hold of their territories in Eastern Siberia and turn them to better account.

IMPORTS OF TEA INTO THE UNITED STATES.

These show a gain over last year. The March imports as compared with last year were light, being only 2,244,783 pounds, against 5,640,951 pounds in 1890. For the nine months ending March 31st the imports were 75,609,214 pounds, against 71,792,298 pounds for the same time in 1890.—*American Grocer.*

THE NEW FORMOSA TEA CROP is larger and finer than it has been for many years. The grower thus far have been a little uppish on account of the superior quality of the leaf, so that the chief if not the sole buyers thus far have been the Chinese hong. The increased output however will soon cause a fall in prices and a heavy shipment to Amoy.—*Amoy Times.*

PEPPER, PADDY, TIGERS, AND BAT CAVES IN PERAK.—The Report on Trong and Kurau, for April and May, stated:—

During the month I walked through the pepper garden of Haji Melomed Yusuf (the Assistant Katbi) at Ayer Terjun (Ulu Sungai Tinggi), who has taken a lease of 80 acres for pepper cultivation, but only from 15 to 20 acres are at present planted, none of the plants being more than 2½ years old, but looking strong and healthy, and had they been trained up dead-wood posts, instead of up dadap trees, the owner I venture to say, would have had a return from the plants this year. In a small pepper garden from 7 to 8 years old the plants having been trained up dead-wood posts, are in full bearing, and looking remarkably well. The owner might have congratulated himself had he had 100 or 200 acres planted up with such pepper. The inhabitants are evidently keenly alive as to the pepper future of the district, as fresh applications for land to cultivate pepper are coming in fast.

The padi crop usually a remarkably good one, was this last season partially destroyed by rats.

It would be a good plan to try the system of poisoned grain adopted throughout the Australian colonies for the destruction of rabbits, and which so far has been the only reliable exterminator of that pest, though scientific men have racked their brains to substitute a better mode of destruction, but without any great show of success.

Since my arrival in the district two tigers have been shot by Mat Salleh, a Patani man, the same man having shot no less than five of them within the last three months, whilst there are several more in the neighbourhood, as was proved on the night of the 18th, a settler having two of his cows killed and eaten, and a third seriously injured. The brutes are of such a ravenous nature that they carried away and ate up the body of a dead comrade killed the previous night. Doubtless they are attracted by the herds of Indian cattle allowed to run loose in the kampungs during the night. All were shot by spring guns ingeniously set in the jungle. A well-known gentleman having offered a reward of \$50 for the dead body of the first large tiger brought in, there is every reason to believe that, in this district at any rate, their extermination is at hand.

The Batu Kurau rock, standing about a mile from the foot of the Hijau range, is worthy of note, and well worth a visit. It is an isolated, perpendicular limestone rock of several hundred feet in height, now overgrown with trees, with the Sungai Kurau winding round the foot of it. The largest cave of interest is on the eastern side of the rock, about 50 ft. in length, and proportionately broad, into which I rode a large elephant; at the further end of this cave gapes an enormous black cavern, extending perpendicularly upwards; I had no means of ascertaining to what height it ran. Thousands of bats were flying in the darkness, frightened at our approach, their wings making the caves resound with a noise like distant thunder, whilst the floor of the cave was from 4 ft. to 5 ft. deep in bat guano. There are several other caves of minor interest in the rock, said to have been the lairs of wild beasts, in the remembrance of the oldest inhabitants.

Correspondence.

To the Editor.
SILKWORM REARING.

Agar's Land Estate, June 17th.

DEAR SIR,—Those who go in for the rearing of silkworms may be glad to know that the wild olive or weralu (Sinhalese name of plant) will do for feeding the silkworms on. I have had both Tussa and Atlas variety feeding on weralu trees at one and same time. Although found also on the cardamom bushes and placed on weralu trees, the variation in their diet does not seem to check their growth, or kill them off. The Atlas variety are only found on the cardamom bushes. I have never found the Tussa variety on these bushes.

The Tussa silkworms are found on 3 different variety of trees up here, Weralu, Dhang, or Nawa Palum (Tamil name of tree), as well as on a shrub that grows in Cinnamon Gardens and produces a pale violet flower with few petals; grows near swamps, marshy places, and has a black fruit (when ripe) which discolours the tongue when eaten, like ink. I have found the Tussa silk caterpillars on all these trees. I am sorry I cannot give the botanical names of these plants, but can send branches of them to any one inquisitive as to what food to feed silk worms on. I have 3 different kinds of moths which seem to hatch from cocoons of the silkworms.

1st the Atlas, 2nd Tussa, 3rd which I am not sure of is a large white moth, long swallow tails, pink-edged, with half-moon-shaped spots, one spot on each wing. I should be obliged to anyone informing me what this moth is called.—Yours truly
JAMES GRAY.

[The difficulties opposed to sericulture in Ceylon are not, we suspect, so much connected with feeding the worms, as with plentiful and cheap labour in attending to them, reeling off the cocoons, &c.—
Ed. T. A.]

WEIGHING OF TEAS IN LONDON: COMMON-SENSE REFORM URGED.

June 21st.

SIR,—In your issue of 11th Mr. John Hamilton and Mr. Robert Jones give us information about weighing and taring tea, and wash their hands in innocence. As one of your readers I thank them, and would like permission to ask them to tell us why the packages are tared at all and how to get about avoiding it? If I mark my tea "nett 100 lbs.," what has the weight of the package to do with it? I sell the tea and give the package into the bargain! If there are 100 lb. tea in the chest, deduct one lb. for draft, if it must be so, and pay for 99 lb., but why juggle with the empty package and deprive me of another pound or two? If my tea is short of the professed 100 lb. I'll bear a reasonable fine if need be.—If India and Ceylon took up this point and memorialized the Government to order the Customs to weigh to half a pound, they would soon compel the buyer to carry on his purchases on the lines of simple justice, with an extra pound for his pains!—Yours &c.,
A TEA GROWER,

NO. II.

London, June 5th.

DEAR SIR,—Your *Overland* numbers with news to the 30th April and 5th May contain some correspondence regarding tares and loss in weight

on teas shipped to this market which are couched in naturally indignant terms; but natural only because the writers, smarting under losses of tea as shown by account sales received from their agents, are ignorant of the way in which such losses may and do arise. The explanation of these losses might well be left to the respective agents of your anonymous correspondents had not you, sir, given apparently the sanction of your influential journal to charges and statements, which no doubt the writers themselves, if they knew the facts and saw things for themselves, would be first to allow were unwarranted. It is perhaps repeating an old story to show how losses in weight may be incurred. The custom of the trade in weighing is to weigh to the lb. only and in doing so to give the turn of the scale both in weighing gross and taring, against the shippers and in favour of the buyers. The Ceylon and Indian Associations in London have endeavoured to get this custom modified and weights taken to the half lb., but so far without success. As it stands now the teas are first weighed gross and if then a package is only one ounce short of the full lb, 15 ounces are thereby lost thus: 135 lb. 15 oz. gross would be called 135 lb. Then the teas are turned out to be tared, and in weighing the tares if the package weighs only one ounce over the full lb. again 15 oz. is lost; to the shipper thus 36 lb. 1 oz. would be called 37 lb. So that nearly 2 lb. may be lost on a package, equal to 2 per cent on chests or 4 per cent on half-chests, in addition to the trade allowance for draft. The trade is so strong that it can maintain this system against sellers; and all that planters can do is to adjust their gross weights and tares so that the minimum loss may be attained. This requires close care and attention, and it is difficult to achieve because of the variability of the tares. That it can be done with some exactness has been proved by shipments from one estate which I know, which for the whole of last year showed a loss of only a quarter per cent beyond the trade allowance for draft. With regard to the dock company or companies it is a mistake to assert as a "Proprietor" does that they form a "monster of monopoly." There are numerous wharves competing with the docks for tea or other produce; and as a proof that charges are not over-remunerative, I may mention that a wharfinger who has a good connection with Ceylon merchants lately thought of adding a Tea warehouse to his other business; but on looking into the matter found that there was little inducement in the way of profit, though he had plenty of promises of support. Shippers and merchants may employ inspectors to see their tea weighed and tared. At a fact this duty is generally left to the brokers who have representatives at the warehouses. The refuse and sweepings which the dock companies and wharves sell from time to time, and which relatively to the bulk of the trade are of infinitesimal importance, would not be thus treated if the importers considered that they were worth more than the duty and dock charges.

A long experience, extending to nearly 20 years in London, enables me to assert with confidence that both docks and wharves in London do their work well and honestly. There is no difficulty in the way of any planter visiting London, satisfying himself on this point. The Ceylon Association in London two years ago thoroughly examined into and sifted out the whole matter of Taring and Loss in Weight, with the result that though it was considered that the system of weighing above referred to was in itself unfair, it was fairly carried out by the dock companies. To assert as a "Sufferer" does that "a considerable percentage of tea is being habitually stolen in the London Warehouses" is to

anyone acquainted with the working of tea here, as foolish as it is untrue. I apologize, sir, for encroaching so much upon your valuable space, and will only add in conclusion that I do not hold a brief for the dock companies or wharves, nor am I in any way whatever interested in any of them, but simply write in the desire that the truth should be known and in the interests of justice and fair-play.—I am, &c.,

THEO. STRETCH.

OUR LABOUR SUPPLY AND COMING LARGE EXPORT OF TEA; LOSS IN WEIGHT.

DEAR SIR,—As an export of from 100 to 120 million pounds of tea in the course of a few years is considered possible it will be interesting to consider what labour is necessary to produce that quantity. From what data I can get I find that it takes the labour of 10,000 coolies working five days per week for 50 weeks to produce five million lb. of tea; therefore our present labour force is for tea alone, at this rate, 120,000 coolies for 60 millions of lb.; and if we are to export 120 millions in five or six years this labour force will have to be doubled in that time. This is a big order, and it is probable that our production of tea will not increase at the rate some expect as the yield will be limited by the labour available and not by what the planted acreage is capable of giving. No doubt, our exports this season would be larger with more available labour, but it is probable that the loss will be partially balanced by this restriction of yield as with a larger export prices would have fallen lower than they have done.

It is strange that an old-established imposition should be tolerated with scarcely a murmur, while a new one such as the increased military contribution raises such an outcry. The loss in weight on Ceylon tea this season will be at least a million pounds which at 10d per lb. comes to more than £40,000, sterling, and the loss on other products, such as cacao etc., would swell this large total still more. It would be better for us if this million lb. were destroyed, as under the present system it assists in depressing the market without in any way benefiting the producer. Could not the Home Government be moved to help us as some return for our increased contribution? It would pay us to lay out £10,000 or £20,000 to have our teas re-fired and packed to correct weights after or before passing Customs in London, any surplus to be sold on snipper's account. Perhaps the Committee of the Tea Fund will find a way to save some, at least, of this large loss which will grow still larger with an increased export, the loss on 120 millions would about pay the whole military contribution. What is considered an unbearable tax on the whole Colony will, if things are not altered in a few years, have to be paid by a section only, viz., £80,000 to £100,000 loss in weight on Ceylon tea alone.—Yours truly, B. B. B.

120,000,000 lb. at 2% loss = 2,400,000 lb. at 10d = £100,000.

PROSPECTS OF TEA.

DEAR SIR,—Is it not strange that in England and Victoria the reduction of the duty has been followed by prices, lower perhaps on the average than tea ever fetched before—that is Indian or Ceylon tea? You may remember how coffee bounded upwards, newly twenty years ago, when Lowe's budget took 1½d per lb. off the duty. It shows the keenness of the competition now-a-days, when the large firms dealing on the packet system push their trade among the customers of every village grocer.

An extensive tea dealer in London told me a short time ago that he had sent out 1,000 circulars to gentlemen, clergymen and leading householders throughout Britain; and that, to those from whom he had no reply or order, he made the members of his family send out a second reminder. He also said that since the establishment of the large London houses in the packet trade, tea once down had never risen again unless in a temporary spurt, because those large houses advertised lower and lower rates, and have never once raised their prices. I see it is proposed to raise the duty again in Victoria.

Here is a report on Ceylon teas in Melbourne received from a leading broker by last mail:—
"Ceylon Teas.—Business has been very dull in this description of tea, and sales when made, have been at a sacrifice. 500 packages were offered at public auction this week. Many teas sold, several parcels under cost price, and the highest bid for a very choice hill tea was 2½d under invoiced price."—Yours faithfully,
PLANTER.

THE LABOUR ORDINANCE.

DEAR SIR,—The Labour Ordinance has been, ever since Sir John Phear's time, the one piece of legislation must frequently construed in utterly unexpected directions. The last ordinance was delayed in order that it might be perfected; Sir A. Gordon certainly sought to make it so; our present Governor told us only lately that the best thing he could do for us was to leave us alone; our Planting Representative was commended at every district and at the Planters' Association meeting, for his powerful grasp of the subject;—and yet there never were so many weak points discovered—I will use no stronger word—as during the last three months. We don't at the present moment know, who has authority to give orders; who has one-third of our force (minors) are amenable to any Labor Ordinance whatever; or what are the advances which we are entitled to set against wages. Surely it is not beyond the ingenuity of our Government's legal advisers so to define these matters, that no one can be dull enough to misunderstand, or misconstrue, the intentions of the framers of the act.

Meantime we cannot deny that many stupid cases have been brought into Court recently, and that others have failed for want of evidence which might easily have been forthcoming. But I think we should all try to manage our coolies out of Court. Be true to ourselves, refuse all coolies not holding a proper discharge from previous employers, keep out of Court as one avoids endless troubles.

Stick to the kangani system, and have none of busybodies however polysyllabic, and Ramasamy will in future, as of old, prove the most docile and useful of laborers. His lot in Ceylon was never so good as now—and he infinitely prefers tea-plucking to coffee-picking, with its attendant heavy transport of wet cherry.
ONLOOKER.

THREE RUBIES, uncut, were sold by auctioneers yesterday, of a size, never before seen in England, or even in Europe. These were the property of the Burma Ruby Mines Company (Limited). The first, which weighed 1,185 carats, was irregular in form, and resembled quartz, save in colour, which was deep red. Biddings commenced at 200l., and rapidly advanced to 400l., at which it was sold. The second lot weighed 302 carats. This was yellowish red in colour, and sold for 65l. Lot 3 weighed 281 carats, was dull red in colour, and brought 52 guineas.—O. Mail, June 19,

UVA PLANTING REPORT.

Badulla, June 25th.

Bright pleasant weather, with an occasional shower, is the order of the day. A good deal of wind on the higher estates, but no harm has been done, and it will help harden the wood of our August and September blossoms. Tea has to a certain extent shut up. But it is somewhat of a relief to have a little breathing space after the continued strain of keeping up with the rush of leaf during the past three months, and to be able to devote a little attention to other works. A very severe attack of leaf disease general in the district. We are all however now accustomed to regard this disease with a certain amount of complacency, after our experiences with bug. In the one case, we know that in a few weeks our coffee will, at any rate, look as well as ever. In the other, we cannot avoid wondering whether the present attack may not leave us without any coffee at all. There is very little bug for the time of year visible at present, and I trust it may give us no more trouble and betake itself to pastures new. Autumn crops are generally good, and with favourable weather there is no reason why spring crops should not be equally satisfactory. Coffee has done very well in this season and has ripened its crop and stood its crop better than it has for years past. A good deal of land being cleared for tea this year and clearing works have commenced on some estates. Tea pruning has commenced, and next month will see a large acreage pruned down.

THE BRAZIL COFFEE RECEIPTS are realizing the high estimate of 5,250,000 bags to which the house of Messrs. J. Bradshaw & Co. have persistently pinned their faith, against the general belief in a much lower figure. The biggest export of coffee from Brazil on record was 6,711,000 bags in season 1882-83.

THE PLUMBAGO INDUSTRY.—This industry has recently assumed large proportions consequent upon rich finds and good prices, and large quantities of the mineral are being brought into Colombo from distant places. Padum Korle and Rayigam Korle in the Western Province, with Howagam and Siyana, contribute a large quantity, while the Southern Province, and the Province of Sabaragamuwa and the North-Western Province, contribute largely almost daily to Colombo. Hundreds of people are employed in the pits, most of which we are worked by means of improved machinery which the proprietors have got out. The native merchants engaged in the industry in the Kurunegala district are looking forward to the day when the railway will be opened to Kurunegala, as it will afford an easy means of transporting the thousands of tons of plumbago sent from that district to Colombo.—*Cor.*

IRRIGATION.—The reclamation of arid lands by means of irrigation is of historic and ancient origin. China has had its artesian wells for irrigating purposes for more than 3,000 years. The table lands of Arabia support a population of 12,000,000 who raise wheat, barley, millet etc., from a soil penurious of vitality without the aid of artificial irrigation. Algeria is practically a desert, but its broad plateaus of sand are made productive by the same means, no less than 12,000,000 acres being reclaimed by artificial processes. In Mexico and South America there are 2,500,000 acres fertilized by borrowed waters, in India 30,000,000 acres, in China 60,000,000 in Japan 11,000,000 in Egypt 6,300,000 and in antipodal Australia some 200,000 acres are made green and productive by the irrigation method.—*Louisiana Planter and Sugar Manufacturer.*

TEA AND COFFEE IN BOND.—According to the official statement of the quantities of bonded goods remaining in the Customs and Excise warehouses of the United Kingdom, as published in the B Bill of Entry, the stock of tea on May 31st was 79,020,834 lb, against 85,239,538 lb in 1890, and 78,940,549 lb at the correspondent period of 1889; coffee, 236,924 cwt against 377,688 cwt. and 460,148 cwt.—*H. and C. Mill.*

AGAINST CHEAP TEAS.—A Stockton firm of grocers recently offered a prize to grocers' assistants for the best essay on tea. This essay, won by a Mr. Laing, has just been printed, with an introduction by the prize-givers, in which they say:—"We unhesitatingly state that no tea offered to the public at a less price than 1s. 10d. per lb. can be a fit or wholesome article for consumption." Speaking of inferior teas they say:—"These teas are not cheap at any money; a greater quantity is required to brew a fairly strong cup of tea, and when made more or less to the satisfaction of the tea-drinker it will contain some 20 per cent. of tannic acid, a substance which speedily destroys the coating of the stomach, and turns wholesome meat into a hard and indigestible substance, just in the same manner as tannin is used at tan yards to cure cowhides and make them fit for leather."

THE TEA MARKET.—Of Indian and Ceylon tea and last week's sales the *Produce Markets' Review* says:—"The value of Indian tea shows no change of importance, the good, medium, and finer grades being a shade firmer, while the lower descriptions have sold at above late rates. The moderate quantities offered at the public sales mainly consisted of the inferior descriptions, and it appears evident that the supply of tea worth over 1s. will for some time to come be very small. The few lots of new season's brought forward were, as is generally the case for the first arrivals, not of a very desirable character, the infusion being thin and showing a want of proper manufacture. As this is not unusual with the first shipment, it is no criterion of the quality of future imports, which is likely, judging from recent reports, to be quite up to the average of past seasons. The figures of the past month are less satisfactory than the trade has hitherto been accustomed to, which is mainly to be accounted for by the poor selection and the high prices for the common grades compared with the lower Ceylon growths. A marked improvement has taken place in the demand for Ceylon teas, and consequently prices have improved for all grades.

INFLUENZA AND ITS CURE.—The *Spectator* has a good word for quinine and of all things "snuff-taking," in winding up a long and rather despondent article about the new pestilence which threatens to become an annual visitor. In conclusion our contemporary says:—

We shall have good reports this time on the disease when it passes, and we may perhaps have some lucid suggestion, or, at any rate, a suggestion on which doctors agree, as to the best preventives. At present, everybody has his own panacea, though, fortunately, this year preposterous doses of antipyrine are not among them. It is difficult even for laymen to touch the subject without offering them, so we will yield to the weakness by ending this paper with two suggestions.—The first given only for its interest to a minute and rapidly decreasing class, the other because we rather believe in its virtue. Let snuff-takers postpone abandoning that dirty and ugly practice till the pestilence passes away, for the queer instinct of the common folk, which suddenly doubled the sales of Scotch snuff, has probably a basis. Tobacco is of no use as a prophylactic against influenza, but the thickening of the mucous membrane, which comes of snuff-taking, is probably a protection, and points to a quite possible preventive. So also, and a much better one, is solid quinine, the only protection against aguish fever which travellers in the tropics trust. Influenza is certainly an aguish fever of some sort, and there is no protection like a daily pill of three grains of quinine, a recipe which has at least this advantage, that it can do nobody any harm.

CEYLON TEA FOR RUSSIA.

A Ceylon colonist now in England, writes:—"I send you a cutting from the *Morning Post* of the 26th May about Ceylon tea which may be of interest to planters. The hint to cultivate it for adaptation to Russian water may be of use if the idea is practicable. Ceylon tea is used almost everywhere in the old country especially after the recent high price which it fetched:—

One of the most interesting of the series of consular reports presented to Parliament this Session is largely devoted to an examination of the causes which have led to the supplanting of China tea in the British market by the competing growths of India and Ceylon. The subject has been alluded to by the present Chancellor of the Exchequer in several of his Budget speeches, but it is doubtful whether the general public yet realise the magnitude of the change that has taken place or the causes which have brought it about. Upon these points the report of Mr. Gardner, our Consul at Hankow, which has just been issued, supplies much information. In his opinion the competition of India and Ceylon net only is fast ousting China tea from the British market, but is destined at no distant date to make serious inroads upon the business of the Chinese tea producers with Russia. During the last five years there has been a steady process of decline in the tea exports from Hankow to London, and whereas in 1886 they amounted to 39,545,000 lb., last year they had fallen to 11,314,000 lb. Startling as these figures are, they do not represent the full effects of the competition of our Eastern possessions, for it is stated that very little even of the small quantity of tea exported to London in 1890 went into British consumption, most of it being sold here for the Russian market. In the same period the exports to Odessa rose from 9,899,000 lb. to 22,742,000 lb., the increase being attributed to increased shipping facilities, improved land transit in Russia, and the greater prosperity of the mass of the Russian nation, which led to an unprecedented demand for tea, especially of the finer sorts. The causes that have made England buy her tea in India and Ceylon will, it is predicted, speedily cause Russia to buy also a customer of those countries. Though for a long time to come she may still prefer Chinese tea, the strength of the Indian tea and its cheapness and the flavour of the Ceylon leaf will more and more commend them to the Russian retailer as profitably to be mixed with the Chinese teas. Cheapness and quality being the two great factors which have enabled India and Ceylon to dispossess China of her supremacy in the Western European market, it needs no gift of prophecy to foretell that their successful competition will rapidly make itself felt elsewhere. The tea trade of China with Australasia is already being affected, and in America and Canada, where principally green tea is drunk, there is a promising field for future extension. One of the advantages which Indian and Ceylon tea growers have over those in China is their greater command of capital. The tea estates being generally owned by companies, expensive land, machinery, and plant, can be purchased, and large sums can be expended on experiments, on agents, and on investigating the tastes and requirements of purchasers. Then loans can be obtained at from 4 to 5 per cent interest, whereas the Chinese grower has to pay from 20 to 30 per cent. The latter, moreover, has to bear not only a heavier land tax, but also a skin and export duty often amounting to 30 per cent of the selling price of the tea abroad and to 100 per cent of the prime cost of its production. The Indian and Ceylon agriculturist has the further advantages of a better labour market, easier modes of transport, nearer access to the markets, better public works, preventing or mitigating the disastrous effects of floods and droughts, improved machinery, and enormously larger tea estates on which the various processes of preparation, picking, and carriage can be carried on without intermission or risk of deterioration through exposure or delay. He has also greater knowledge of the methods and requirements of the retail dealers, and can command the services of chemical and agricultural science. How important this last-mentioned point is, Mr. Gardner

remarks, none but an expert can explain. He gives, however, one illustration to show how science may be applied in order to enable the tea planter to adapt his crop to the requirements of a particular market. One of the chemical ingredients of tea is tannin, which gives the tea its bitter and astringent flavour. In some parts of England the water is of such a nature that it does not easily assimilate with the tannin, and for these regions a tea containing much tannin is desirable. The water on the plains of Russia, on the other hand, readily assimilates with tannin, and hence the tea required must contain only a little of that ingredient, or else it would be too bitter and astringent to be saleable. The tea planters of Ceylon and India have the necessary knowledge of agricultural chemistry at their command to produce in the tea, by cultivation and manufacture, the requisite amount of tannin* for the market which has to be supplied. As between the producers in our own dominions and those in China it is the old case of scientific knowledge *versus* "rule of thumb." The Chinese tea grower, working for his own band instead of for wages, brings often greater care and more industry to the task—and this is the one advantage he possesses against those which have been enumerated as belonging to his Indian and Ceylon competitors. Experience, with him, takes the place of science, and if he is still able to produce a finer flavoured tea than has yet been produced in India, his superiority in this respect is not likely to remain long unchallenged. The extent to which his former monopoly of what is now almost a necessity of life has been destroyed is, perhaps, the most remarkable illustration that could be adduced of the boundless resources comprised within the limits of the British Empire.

PLANTING NOTES FROM THE NILGIRIS.

COONOR, May 31.—The coffee season of 1890-91 is well nigh over, only a few of the estates at high elevations having any berries left on them. None of the estates during the past year gave bumper crops, and only a few yielded average ones. High prices have, however, compensated to a great extent for short yields, and planters are on the whole fairly well satisfied with past results. Prospects for the season 1891-92 are very good indeed; the weather has so far been most favourable, and there has been a good show of blossom on most estates. Some of the sanguine planters expect (always expected but, of late years, never realised) bumper crops; but leaving the over sanguine ones aside, if the weather continues favourable, very fair average crops will probably be the yield of most of the estates during the coming seasons and in my opinion average crops are to be preferred to bumpers. Allowing coffee trees to over-bear is a very great mistake. They get so weakened after a too heavy crop that they fall easy victims to every disease that coffee trees are heir to, and many a good estate has been permanently damaged by over bearing. In fact, neither leaf disease nor bug has played greater havoc amongst coffee trees than too heavy crops. With judicious pruning and bandling crops can to a great extent be regulated according to the strength of the trees. Planters on the Nilgiris, except here at Kotagerry, are never troubled with the labour question, and are in that respect better off than their brethren of Coorg and Travancore. We neither require nor employ Labour Agents; the chief part of our labour is drawn from villages in the District of Coimbatore. On nearly every estate a few Canyases from Mysore are also employed, and on some Maligars from beyond Bellary. But it is in the Konga coolies of the Coimbatore District that the Nilgiri planter has to put his trust for the execution of his work; and provided he can speak the language spoken by the Kongas (a very poor apology for Tamil) not merely etymologically, but with the peculiar twang of the Kongas, (which is the most important part of their language), he can procure any number of coolies on

* This is just what Mr. Hooper, the Madras quinologist, held could not be done. Such was his conclusion derived from a number of tea analyses.—ED. T. A.

short notice and small advances. A Konga mistakes a Sahib who speaks his native tongue like himself for some sort of a distant relation, and he seldom deserts such a Sahib for trifling causes. The Konga likes to get his weekly advances of from 3 to 12 annas; and to his credit be it said, that although Government has most considerably to the cooly, and considerably to every one else, placed liquor shops in every nook and corner of the Nilgiris, he spends nearly the whole of his weekly advances on food. But on the monthly pay day, which is invariably a Saturday, he spends a part of his earnings on arrack, and the Sunday succeeding pay day is generally reserved by him for settlement of disputes with his fellow labourers, which, however, are never attended with broken limbs or bloodshed, as the Kongas are wise in their generation, and while they abuse each other in the vilest language and call each others forefathers all the abusive names they can think of, they stand about 10 yards apart, and after exercising their lungs for a couple of hours they return to the same lines and live in peace and harmony until next pay day.

Hitherto, as I have already said, Nilgiri planters have been well off for labour, but it is doubtful whether we shall be as fortunate in the future. The railway line between Coonoor and Mettappolium has been traced and as soon as certain disputes are settled between the Government, the Railway Company, and the planters, with reference to the amount of money due to planters for the portions of their estates taken up by the line and for the damages that may be done to the adjacent parts when the line is being opened, work will commence, and as a very large number of coolies will be required for the earthwork, there will be a great strain on the labour market. I believe ordinary labourers—for skilled labour is to be imported from elsewhere—will be drawn from the Coimbatore District, and as some thousands of heads will be required for this work it will, to a certain extent, interfere with estate labour. It will be a very serious matter if labour falls short during the picking season, and it will be advisable therefore for planters to anticipate matters and to enter into early contracts with maistries for a sufficient number of hands for their estates. There is another question to be considered in connection with the railway works, and one which is of far greater importance than the mere number that may be employed by the Railway Company, and that is the rate of wages the Company intend paying their coolies. The present rates of Rs. 3-0 per man and from Rs. 4-0 per woman for a month of 26 working days, were fixed some years ago, after taking into consideration both the requirements of the coolies, and the paying powers of the planters. But if the railway contractors should either through ignorance of present rates or through some short-sighted policy, raise them they will be doing a great deal of damage to planters and residents on the Nilgiris without in any manner benefiting themselves; for as soon as the rates are raised by one party, the others will be compelled to do the same, and thus no advantage will be gained. Hitherto Mr. Woolley has acted in a right spirit with regard to the rates of pay for coolies employed by him for surveying the line, and although he had at first some difficulty in getting men for a work new to them, he overcame them without enhancing the rates. But as contracts will have to be given to different parties, and stipulations are made in the contracts with regard to coolies' wages the contractors may give higher rates than those at present in vogue and do a deal of mischief. There has been some talk among planters on this subject, but nothing definite has as yet been done to prevent an impending evil. The sooner, however, something is done the better.—*Madras Mail*, June 2nd.

HEMILEIA VASTATRIX.

To the Editor of the "*Madras Mail*."
Sir,—Reference to the correspondence that has appeared in our columns during the past month, on

the subject of *Hemileia Vastatrix*, and more especially to Mr. Pringle's assertion that he has discovered a remedy for it, which he is willing to communicate to the planting community for a consideration, would it not be well for each of them as feel disposed to entertain his proposal to first ascertain from Messrs. Matheson & Co., or from their Agent in Coorg, what has been the result, in this way, of his experiments on their behalf? Mr. Pringle states that he has been employed for four years on this and kindred subjects at a cost of £5,000 sterling, and the inference from his offer is that he has given his late employers a *quid pro quo*. I do not think Messrs. Matheson & Co., or their Agent in Coorg, could have any objection to answering a simple question of this kind, which might be so put as to take in the borer difficulty also.

PRUDENCE.

Pollibetta, South Coorg, June 5th.

THE ART OF MANURING COFFEE.

To the Editor of the "*Madras Mail*."

Sir,—I feel sure that all interested in coffee will join with me in thanking you for publishing, and Mr. Pringle for writing, the interesting, valuable and suggestive paper on "The Art of Manuring Coffee" which appeared in your issue of the 9th instant. The discussion of the numerous points connected with the cultivation of coffee is of the highest value, and if planters can only be persuaded to publish in your columns the result of their experience, the *Madras Mail* will soon become in India all that the *Ceylon Observer* is to the interests of that Island. My object in writing now is to ask Mr. Pringle if he has carried out any experiments in Coorg as regards the green manuring to which he alludes in his closing remarks. The subject is one of great importance. Baron Rieby (?) called attention to it many years ago, and suggested that lupine might be sown with advantage between the rows of coffee in Ceylon, and I may mention that I am now making some experiments with various leguminous plants in my plantations in Mysore. But if leguminous plants are valuable from their power of taking up and retaining nitrogen from the atmosphere it is possible that coffee might be much benefited if we used leguminous trees as shade, and I venture to suggest that this point is worth looking into. It is supposed that leguminous plants take up and retain, through the medium of nodules on their roots, the nitrogen of the atmosphere. Now, I am informed by a very competent observer that he has noticed nodules of a similar character at the roots of a leguminous tree, and it is therefore probable that these roots are as rich in nitrogenous matter as are the roots of clovers and other leguminous plants. And if this surmise should turn out to be correct, and our coffee were shaded with leguminous trees, we should, when digging, be constantly cutting many of their roots and so obtain cheap supplies of nitrogenous matter. I am now going to make some experiments with leguminous trees and shrubs, or rather very short trees, as shade for coffee, and I would suggest to other planters to do so too. Mr. Pringle alludes to land becoming coffee sick, and doubtless it must often become so; but the land does not necessarily become so even when kept for a very long time under another crop but coffee. One of the oldest pieces of coffee land that I have seen was opened in Mysore about 95 years ago, and when I saw it some years ago the coffee could not be surpassed, and there seems to be no reason why the land should not go on bearing coffee for as long as the world is likely to last.

Ootacamund, 11th June. ROBERT H. ELLIOT.

PEARL FISHERIES OF CEYLON

(BY A ROVING CORRESPONDENT.)

The fishing grounds are reached by steamer from Colombo, which conveys the visitor to the northern parts of the island. All the luxuriant foliage, the leafy janas, the wonderful growth of palms, creepers, and gorgeous flowers are left behind. The home of the pearl oyster is off a flat low-lying coast of barren sand. For miles inward towards the interior, the country is sterile and repulsive; the only wood that thrives here are the umbrella plant, the cruel prickly buffalo thorn, and the monstrous "hoabah" tree, whose abort-stunted growth and ragged branches can withstand the strong gusts of wind which sweep over the desolate sand. This tree was mysteriously imported from the West Coast of Africa in distant days—a huge shapeless mass of wood from twenty to thirty feet in circumference, and very little more in height. The long sweep of desolate shore has a dreary appearance, and seems a fitting abode for great crabs, tortoises, and snakes. On those sands, where the sea-turtle basks in peace, and the solitude is only broken by the wild cry of the sea-fowl, crowds assemble as soon as the pearl fisheries begin, and the dreary waste becomes enlivened by numbers who congregate from the distant parts of India. The shore is raised in many parts to the height of several feet, by enormous mounds of shells, the accumulations of ages. Here the millions of oyster shells, robbed of their pearls, have been year after year flung into heaps that extend a distance of miles. These heaps shining bright on the beach add to the glare, while the burning heat of the sand under a noonday sun is almost unupportable. The flat shore all round is riddled with holes by a large oycypid, who must be terribly surprised at the invasion of his territory. Those huge creatures suffer from the general barrenness; their food is scant, for if one of their number is killed and left on the shore, his fellow-creatures promptly carry him away into a burrow and doubtless devour him.

The only inhabitants are a few fishermen, who find a modest living by onring shisks and other buoy fishes, finding a market for their poor stock in the forlorn peninsula of Jaffna.* Hops is kept alive in their breasts by washing out the forsaken "Kottus," in search for pearls, lost by the gleaners of other days. The inhospitable shore is further haunted by sharks, sea-eagles, and black and yellow snakes that frequently dot the surface of the water over the oyster banks. A pitiless sun flings down burning rays on the shifting sands, and over its surface sweep clouds of big red-eyed blue-bottle flies, helping the process of putrefaction, as the pearls are not removed till after the fish has decayed. At Mavrecha Khadi I found hundreds of half-naked Arabs, yellow-skinned Moors, Afghans, Malays, Tamils, and Sinhalese divers, traders, pedlars, *jukeers*, conjurers, a heterogeneous mixture of thousands of different colours, countries, castes, and occupations. On the shore, a large town had sprung up, consisting of tents, cadjan huts, bazaars, and the rudest edifices. The roofs of these temporary dwellings presented an unusual spectacle, every imaginable article of clothing was spread thereon to dry cloths, turbans, and jackets of every possible shape and colour met the eye in every direction. In the front of the huts were mats, on which were heaps of black-looking earth. Watching these carefully, were seated greasy Chetties with massive head-curtain rings of gold in their ears, and sleek Moors, with cold calculating eyes, almost wide, [nude?] whose attention could not be distracted from the operations going on before them. This work was being undertaken by women and children, who were busy sifting the heaps consisting of shells, sand, and all the filth that remained after washing the putrid flesh of the oysters on their removal from the shells, in search of any of the remaining precious pearls. The pestilential

smell of putrefying fish poisoned the air, and became most offensive when the wind blew from the south. The putrefaction of millions of oysters generates an immense amount of worms, flies, mosquitoes and vermin of all sorts. To guard against disease, a hospital and medical men were provided, and a rigid scrutiny is made of all the arrivals to guard against infection. Every precaution to prevent cholera or small-pox patients coming from other parts of the island is also adopted, for Ceylon at present has not a clean bill of health.

The divers are mostly Moormen and Tamils, with a few Arabs from the Persian Gulf, a brave hardy race of men, of a speculative turn, who betake themselves year after year to this hazardous occupation. They usually come in common lighthers, eight or ten tons in burden, such as commonly convey cargo to ships, using both sails and oars; each boat has a complement generally of twenty-one men, with five diving stones for ten divers. The usual equipment is very simple, an open scaffolding to each boat from which the tackle is suspended, and pine-shaped stones of coarse granite, from 30 to 50 lb. in weight, with a loop attached to each for receiving the foot: some divers use half-moon stones to hind round their waists that the feet may be free. The diver is also provided with a small basket, or bag, woven like a net, which he takes down to the bottom, and filled with the oysters as he collects them; and the rope is attached to his body, the end of which is held by the men in the boat. This rope he jerks when he wishes to be drawn up. While five divers are coming up, five are preparing to go down. When the diver reaches the bottom, he throws himself on his face and collects all he can. If the bank is rich, about 150 oysters can be taken in each dip; if, however, the oysters are scattered, not more than five to ten. The Arab can remain submerged for about ninety seconds, while the Moor or Tamil rarely exceeds seventy seconds. The former wears a nose compressor, but the others scorn the use of any such helps. The diving generally begins at sunrise, and continues till the sea breeze or west winds set in. The hours of work do not exceed six. The men enjoy the labour as a pleasant pastime, and never murmur or complain. The noise of going down from the several boats continues without interruption. From a little distance it resembles the dashing of a cataract.

When the day advances and sea breezes set in, the signal is made for the boats to set sail for the shore. It is a lovely sight to witness a flotilla of about 200 boats, with white sails set to catch the breeze, lightly skimming the blue waters in the dazzling sunlight. The oyster banks are some distance from the shore. As soon as the keels touch the sand, eager enquiries are made from all sides as to the results of the day's fishing. The fishing grounds are marked by buoys over the spots, ornamented with flags of different colours, giving the waters the festive appearance of a regatta. In the olden times the Governor visited the scene accompanied by a military guard armed to the teeth, to resist any raid from the Kandyan Chiefs bent on plunder. The beach from Condatohy Bay to the old fortress of Areppo is very convenient for boats, the water being deep close to the beach, and not agitated by any surf. When the signal for work is given at early dawn, the noise and shouts from those embarking is deafening in its clamour. Strango prayers are recited, hasty ablutions performed, and the solemn pall of night is pierced with a conglomerate shout of voices, which to European ears makes a din, strango and unearthly. The divers are a superstitious class given to charms and extraordinary ceremonies. No diver will go under water till the shark conjuror has performed his incantations. † Once the Government had to keep two of these functionaries in its pay, to remove the fear of the divers from their enemies, the sharks. The conjuror is stripped naked and shut up in a room, where he

* Whou ho wants the basket hauled up. The diver floats to the surface.—Ed. T. A.

† This statement raises a suspicion that the account is not first-hand. For many years back the shark charmers have ceased to be employed.—Ed. T. A.

* A most inaccurate description of a scene of exceptional fertility, by means of well and garden cultivation, and densely populated.—Ed. T. A.

mutter his spells in secret from the time of sailing until the boats return. While this is going on, the natives believe that the sharks cannot open their mouths. The waters of Ceylon abound with these remorseless pirates of the deep. Yet strange say to that the number of accidents in the fishing grounds are very few. If a shark is seen, the divers make a signal, when all the boats return; it is not often, however, this occurs, for, whether, it may be the charm or the multitudes or the noise, few of those monsters approach the scene during the diving operations. While at work no food is taken by the divers according to the instructions of the conjuror, else the charm for their protection is broken. They are, however, allowed unlimited privileges in drink. This permission is rarely abused by the divers, who are for the most part abstemious men.

On reaching the shore the boats are made fast, while the oysters are carried on the heads of boatmen to the "Kottus" or palisade enclosures on the sand, where they are thrown into heaps. Some boats land as many as 30,000, while others only five or six hundred. When all the shells are lauded under the careful eyes of the overseers, the whole is divided into heaps, two-thirds going to the Government, and one-third to the divers. The diving operations of the present year have proved a great success, exceeding the expectations of the official inspector. It was estimated that about 10,000,000 oysters could be available, whereas the actual number fished has reached 37,810,552, the Government share of which has realised Rs. 27,031, at an average price of Rs. 2-14 per thousand. The highest price obtained has been Rs. 50, and the lowest Rs. 28. The largest number of boats out on any one day has been 206, and the lowest 35. A further Rs. 1,00,000 should be realised by the Government, if the monsoon will only hold off, as the banks are not nearly exhausted. This is, I think, the largest sum that the fisheries have ever yielded, and is all clear gain to the revenue. I notice from the official statement showing the estimated revenue and expenditure for the year 1891 that the Pearl Fisheries are shown as yielding only Rs. 500! At the close of last year's operations, it was authoritatively asserted that there could be no operations this year, and the estimate of 10,000,000 oysters above alluded to was only an after-thought. Surely, the Government can be better served in a matter of this sort, by having the banks more carefully surveyed by a competent official. Oysters do not form pearls in the space of a day or two. It is to be hoped that all the other estimated figures of the budget will not go away, or there may be a deficit of some sum that will act disastrously.

The representative of the Government promptly holds an auction duly summoned by tom-tom, when its share of oysters in lots of 1,000 each are put up for sale, being knocked down to the highest bidder. The brokers, jewellers, and merchants who congregate bid and outbid each other in the most lively manner. About the same time a great fair is held, at which articles of all description from India and elsewhere are sold. A great number of beggars, cripples, and *fakers* find their way here. I noticed one of the latter who was doing penance, for which he wore round his neck a gridiron about a foot and a half long. I was told this strange ornament was not removed while either eating or sleeping. There were other loathsome practices exhibited, too filthy to chronicle.

The greatest care was taken to prevent theft. Yet I was informed that pearls are dexterously removed from the shells by means of a stiff piece of brass or bramble.

The natives think that the pearl is formed from the dew drops in connection with the sunbeams when the oyster comes to the surface to catch the drops of rain. Some think the pearls are formed as a defence against interior worms, while others state authoritatively that the pearl is the effect of disease. I find it is easier to criticise their speculations than to substitute a more rational theory, which I leave to the reader. Between one hundred and two hundred pearls have been found in a single oyster, while sometimes a hundred may be opened without finding any. The yellow or gold coloured pearl

is most prized by the natives. The largest I saw was about the size of a small pistol bullet; spotted pearls are cheap. For a long time it was supposed that the pearl oyster was anchored to a certain place, and that the crustacean was incapable of locomotion. More recent researches prove that it can detach itself from its moorings and form its byssus at pleasure, to prevent being carried away by the current. According to the statement of one naturalist, an oyster was seen taking a walk round the inside of a "chattrie" and mounting the glass side of a vivarium. They are supposed to change their places a dozen times in a month.

An oyster reaches maturity in its sixth year, and in its ovaria there are reckoned to be about twelve million eggs. Owing to its many enemies it is hardly necessary to add that few of these millions arrive at a mature condition. This curious family of crustacea are so human as to be gregarious in their habits, while they are addicted to night walking, not however, to be regarded as an aspersion on their character like that of the human biped, but solely on account of their enemies, darkness being their best protection. The pearl oyster is, on the whole, a hardy creature, capable of living in brackish water, inclined to leave its moorings if the water gets agitated and disgusted with the conduct of crabs and shrimps, which nibble at its byssus and compel emigration. The shape of this strange creature carrying so valuable a treasure is that of an imperfect oval, while the inside of its shell resembles a silver palace more beautiful than the pearl itself.—*Times of India*.

CINNAMON ADULTERATION IN AUSTRIA.—The Austrian ministry for home affairs has issued a circular to all police authorities throughout the country calling attention to the growing practice of adulterating spice, especially cinnamon, and enjoining a strict application of the laws against food adulteration. The circular states that it has been brought to the knowledge of the authorities that large quantities of hazel-nut shells are brought into commerce by way of Trieste for no other purpose than to be ground up with cinnamon.—*Chemist and Druggist*, June 13.

TECHNICAL SCHOOLS are very much in vogue in England now and the system of education is being extended to the youths of the upper classes. Sir Ed. Hay Currie, the founder of the People's Palace in London, has started one for the sons of gentlemen. Agriculture, Practical Engineering, Electricity &c. are taught with the ordinary subjects of a public school course, and the pupils are made to be proficient in riding, boating, swimming and other manly sports. The object is to make the sons of gentlemen who have to fight their way in the world more practical men as colonists than they are generally now. A knowledge of a few of the sciences with an aptitude for manual work enable a colonist to find employment without any great difficulty.—*Ceylon Colonist at home*.

FIBROUS PLANTS AND NEW PRODUCTS.—Here is an interesting paragraph from Mr. Moir's Administration Report for the Central Province just out;—

Negotiations have been in progress for some months with Messrs. Gordon Keever and W. Gow respecting the lease to them of a large tract of Crown land in Matale East, for experiments in growing fibre plants chiefly and other products. Unavoidable delay has occurred in concluding a formal agreement, but I trust that these gentlemen will be in possession of a portion, at any rate, of the land before long, and that their experiment will turn out a success. The land is, at present, profitless to Government, and success with the experiment would be a great boon to the neighbouring villagers, who are, I understand, anxious to see operations in progress, in order that they may obtain remunerative employment within easy reach of their homes.

PROGRESS IN "WEST HAPUTALE;"

"THE DARJEELING OF CEYLON"; A TEA COMPANY WANTED; ALL THE PRESENT PROPRIETORS TO BECOME SHAREHOLDERS?

We are indebted to a correspondent who supplements the recent notice of this district that appeared in our columns with the following further information:—

"In reading a correspondent's notes from West Haputale in your *Overland* sheet, I see he passed without mentioning Lentrán and Callendor, flourishing tea estates both owned by Mr. Dunsmure, who has established a tea factory in the centre of the Valley. On Wellatenu to Mr. Margary is opening land in tea. There must be well on to 700 acres of tea planted in the Kalupahana Valley out of a total of three thousand acres available in private lands. It would pay better to make it all into a Company with one factory if someone would take the matter up. In addition to being near the railway, the district has the advantage over the old estates in other districts in being all virgin soil, with ample fuel supply, and if properly managed the tea at that elevation should command a better price than the average. There is undoubtedly a fine field for a Company. Some of the present proprietors sank their capital by paying an average of R60 a acre at the Government land sale in 1880; and when cinchona failed, tea was only in its infancy, whereas now it is proved to succeed in the wind, which after all is much the same as in the rest of Haputale. There is a prejudice against Kalupahana, but it is the healthiest climate in Ceylon, and will yet grow the best tea. It runs to 7,000 feet in some parts where the climate and lay of the land has been compared to Darjeeling."

THE COLOMBO PUBLIC TEA SALES.

THE FIGURES FOR THE HALF-YEAR.

The public sales of tea in Colombo for the half-year closed with yesterday's heavy auction, and we have pleasure in supplying our readers with the figures for the six months, and the comparative totals for the latter half of 1890. This is the first year in which the season is being reckoned from January to December, instead of—as in the old coffee days from Oct. to Sept. The progress in the quantity of Ceylon tea placed in the world's markets are well-known to the public; but the figures below show that the tea trade of Colombo from the beginning of 1891 has made even greater progress compared with the total exported. The quantity offered in the local market in 1885-6 was about 20 per cent., while the following year it fell to 17 per cent. Since then, we believe it has not reached, or at any rate not exceeded, the 20 per cent., until the present occasion, for out of about 33,000,000 lb. of tea which by the 30th inst. will have been exported from Colombo since the 1st Jan. last, about 6,776,000 lb., or 21 per cent, will have been offered in public sale by the brokers of Ceylon. This is doubtless a great increase on the previous six months, but we are inclined to believe that it is a sign of greater confidence in the local market which will continue. From July to December last inclusive the number of packages offered and sold were 67,550 and 45,164 respectively as against 96,804 and 69,488 for the present six months. As to the number of lb. they can be easily calculated throughout, at the average rate of 70 lb to a chest or package. The following list, the figures of which we have obtained from our brokers, are for the half year concluded yesterday, and represent the number of packages offered and sold. It will be seen that Messrs. Forbes and Walker still hold a very secure first position, while from the indications of the last quarter more especially, the next three firms, which stand fairly

close together, are engaged in a keen competition for second place, or will be during the coming half-year.—The figures concerning Messrs. Benham's sales are necessary to make the totals.

PLANTING IN PERAK.

We are very pleased to hear of the good work being done in the Straits Settlements by old Ceylon Planters. From a letter just received from Mr. Thomas Fraser, we quote as follows:—

I suppose you have heard of the very favourable terms the Perak Government is offering land for, viz: blocks of 500 acres, of which any applicant can have two and select where he likes, at \$3 an acre and no quit rent and purchase in perpetuity. The Government however may impose an ad valorem duty of 2½ o/o or any part of it, should they wish to do so on the crop exported.

People at home are turning their attention to it and a very considerable acreage has already been taken up on these terms and there is plenty of capital to open it.

Our coffee, Arabian and Liberian, are both doing exceedingly well. The latter has certainly found a home here as it never did in Ceylon. Tea is also doing remarkably well and there is any quantity of land to be had suitable for its cultivation and cheap. I am surprised that some of your old coffee planters have not come over to take up land and so participate in the liberal terms now being offered by the Government.

WESTWARD HO!—THE COMMISSIONERS FOR PERU.

We have a letter from "Old Colonist" dated 31st May from on board the S. S. "Etruria" off Queenstown, Ireland—the precursor, we trust, of many chatty notes to follow. We quote his news so far:—

Here we are so far well and hopeful, the spirit indeed being very willing. Ross has had "La Grippe," but I hope a few days on the Atlantic will set him right. We may have a few days in New York. We are to visit Trinidad, but whether we may find it most convenient to do so in going or coming I do not know yet. This great Yankee liner of somewhere about 8,000 tons is no doubt a smart affair, but there is a quiet dignity about life on board the good old P. & O. which I have never found elsewhere at sea. Dear old "Logie" came down to see us off yesterday and stayed till the boll rang. Very kind of him. How well he looks! When I am asked "Who is the happiest man you ever met?" I'll think of "Logie." I wish he had been going along with us. You will probably see him soon en route for the Straits. Most kind letter from another old colonist, W. Donnán of Belfast today! Wants me to go to South Africa when I return! I presume it will be January 1892, before we can emerge from Peru, Brazil or Bolivia?

THE AMAZON STEAM NAVIGATION Company has sold its hundred steamers, and all its wharves, landings, and warehouses to the Brazilian Corporation, known as the Empresa de Ocas Publicas, for £850,000, making £350,000 by the transaction. This transaction renders the great rubber-carrying trade of the Amazon a Brazilian monopoly.—*Indiarubber Journal*.

CINCHONA BARK IMPORTS AND PROSPECTS.

Messrs. C. M. & C. Wodehouse in their latest monthly Report sum up the total imports of bark into the United Kingdom for a series of years, and we see at a glance how the same has begun steadily though slowly, to decline. The figures extend from 1885 to 1890 inclusive. The import from Ceylon fell off from 12,872,384 lb. (in 1886) to 8,135,156 lb. last year. From India, Java, and other parts of the East there has been an increase, however, the import rising in six years, from 935,264 lb. to 1,588,480 lb. [Of course the bulk of the Java bark goes to Holland.] In the case of South and Central America, West Indies, &c., we have 873,264 lb. imported thence in 1885 and only 335,552 lb. in 1890. Re-imports from the Continent of Europe, however, have increased from 573,120 lb. in 1885 to 1,023,344 lb. in 1890—this means of course Java bark mainly; for the grand total of imports into the United Kingdom, which was close on 1½ million lb. in 1885, and exceeded 16 million in each of the three succeeding years, fell to 1½ again in 1889 and to about 13 million lb. in 1890. This makes it all the stranger, in view of the increase in consumption and the clearing out of bark and quinine in second hands in London of late years, that the market for bark has not improved. That it has not done so, must be chiefly due to Java, which, it will be seen, has more than doubled its total export of high-class bark in four years.

COAL AND OTHER COMBUSTIBLES IN CEYLON.

From the letter of a Ceylon public servant now in England and who shows his patriotism by not forgetting his adopted land, we quote as follows:—

"I met Mr. Blanford of the Indian Meteorological Department lately, and in a discussion about coal in India he said it was not likely to be found in Ceylon, as the strata lying below the mountain ranges were of too recent formation and did not go back to the carboniferous period. The mountains themselves were of crystalline origin and belong to one of the oldest systems of rocks in geology. A good knowledge of chemistry however might lead to the discovery of some substitute for coal, as has been done in Italy recently. A description of this discovery will be found in the enclosed slip from the *Standard* of the 28th May."

Rome, Wednesday Night.—An experiment was successively carried out yesterday which will probably mark the commencement of a new era of prosperity for the mechanical industries of Italy, and especially for her carrying companies. A train was run yesterday from Rome to Frascati, furnished with a new combustible, prepared according to the invention of Signor Sapor, of Siena. It is a preparation of lignite, of which there are immense and rich deposits in Italy. It is found of two qualities, the xilofite and the schistose, of which the latter is the richer in combustible material. In yesterday's experiment the train ran easily and smoothly up one of the steepest gradients in Italy. The quantity of fuel used during the transit was three hundred and sixty-seven kilogrammes, as against three hundred of ordinary coal. The train was a heavy one, of eight carriages and luggage van; and there were seventy passengers, including members of Parliament, engineers, &c.

Lunch was served at the Hotel Frascati, at which toasts were given. An English gentleman said England would witness with pleasure the success of the experiment, and the commercial emancipation of Italy. A telegram was sent to the King, announcing the success of the experiment. A very brilliant gas is also to be obtained from lignite.

The importance of this new manufacture will be seen when it is remembered that Italy now pays from a

hundred to a hundred and twenty million francs yearly to other countries for coal, and that her supplies of lignite are practically unlimited. The smoke from the new combustible is very light, and not disagreeable in colour.

We should be only too well pleased if even lignite were found to exist in quantity in Ceylon. Meantime it is curious we have heard nothing further of the Si-am lignite which, a few years ago, a mining engineer told us abounded in a locality whence it could be cheaply shipped to Ceylon.

SALE OF TEA ESTATE PROPERTY.

A third share of the Mipitiakande estate in the Kelani Valley has been purchased by Messrs. Kennedy & Evans for £5,000 sterling. Mipitiakande has 260 acres of fine tea in full bearing with 112 acres of reserve. The price—£15,000 over all—is a handsome one, equal to £55 per acre for the tea.

COCONUTS AND CINNAMON.

Kadirana, June 20th

After an interval of fine weather, which lasted from the 6th to the 12th, rain set in again steadily yesterday, and the previous night being stormy with heavy rain; the gauge showing 3.46 inches in the 24 hours. The total for the month so far is 8.43 inches. With so much rain and vegetation is looking fresh and green, but it even would benefit by a few weeks of warm sunny weather. The vigour in the cinnamon bushes seems to be forcing out a "bad" which it is hoped will not be heavy, as it would interfere much with the peeling which is now good. The last cinnamon sales in London show no improvement in price or demand for fine spice; this is bad for those who cultivate well, for the preparation of lower quality cinnamon scarcely pays expenses. Ever I regret to say still prevails extensively all over the district; fresh cases are common, and relapses numerous, and this last is the most serious, as each relapse leaves the patient weaker. The poverty of the people will not permit of their lying up till strength is quite restored, for being poor they must work to maintain themselves and their families, and the food they can afford is not what one would prescribe for convalescent fever patients. Quinine is coming greatly into favour, and the various dispensaries and the hospitals are freely patronized. The people are beginning to recognise the fact that by the use of quinine fever can be subdued in a few days before the strength is much affected, while under native treatment the patient as a rule is fit for nothing for weeks after the fever has subsided. This is a serious matter to the poor.

THE STORY OF A TORTOISE.

Mr. J. H. Tuko contributes the following very interesting paper to the *Journal* of the Hitobin Natural History Club for May:—

[After recording the deaths of animals and birds from cold, the writer proceeds:—]

But to my family and myself, the loss of an old friend and summer visitant, who has for more than a quarter of a century amused and interested us by his odd ways and quaint old-world appearance, caused the deepest regret. He was a tortoise. I speak of him as a summer visitant, for with the regularity of a bird of passage he took his departure, leaving no trace behind of the quarters he had selected for his winter residence. It is a curious fact that that the self-burying of the tortoise is accomplished without any visible disturbance or heaping up of the earth, and we have rarely, if ever, been able to discover the precise spot, until on some warm day in the early spring his muddy form was partially seen at the mouth of his hole. Thence he usually confined himself to until he thought the warm weather was fully assured to him.

Then he commenced to ramble about the garden during the day, hiding at night under a shrub on the sunny side of the wall.

"For his winter residence he seldom selected a south aspect. The short grass on the lawn seemed in the early spring to give him the food he needed—dandelion and a variety of young seedlings or tender herbaceous plants were all devoured with evident relish. So much was this the case with certain plants—young *Aquilegia* for instance—that we lost some varieties which we have not been able to replace. But the 'bonne bouche' of the summer was evidently the soft juicy stalk and seed of the *ornithogalum nutans* (Star of Bethlehem). These seeds he devoured in large quantities and they were with the dandelion flower, the only food which we could tempt him to eat from our hands. The ravages he committed led to many complaints from the gardeners and various devices were resorted to, to restrain him within bounds. A low fence of wire netting six inches high enclosing a space of five or six feet square made him a convenient 'pound' where he was fed with lettuce and dandelion; but this imprisonment was evidently very irksome, as he spent most of his days in making a futile attack upon the wire netting; very amusing it was to watch him retreating a few inches from the wire and then with all his force rushing like a battering ram against the obstruction. Whether in revenge or not I cannot say, but of late years the tortoise took great delight in creeping after the gardeners and butting hard against their boots whilst they were engaged in work; and on 'mowing days' especially this became so troublesome that it was more needful to imprison him. In order to give him a wider range we at last resorted to the plan of inserting a wire ring into the outer edge of his shell to which a string was fastened to a short post which could at pleasure be moved to different parts of the lawn. This he more quietly resigned himself to, though it was evidently opposed to his quaintly active habits during the summer days. Even on summer nights he went to bed early. During the past autumn I had noticed that he appeared less active than usual and that food left for him was frequently untouched. The tortoise, however, disappeared as usual when the cold weather came, leaving no trace behind him, and it was only in April when the border was being dug up that he was found, and then, alas, it was discovered that he had perished from the extreme cold, and thus quietly ended his uneventful life.

"The tortoise had grown very considerably since he first came and his shell measured $9\frac{1}{2}$ inches across by 10 inches in length.

"I cannot recall that he evinced any peculiar affection for any of us, and the only sound he ever gave forth was a very angry hissing when lifted from the grass, which sounded like a vigorous attempt at cursing. But for all that we miss him more than many who have seen more, and we can place him among those of whom the poet says:—

'Alas for those that never sing
But die with all their music in them.'

Silently he lived his lonely little life, separated from his kindred, and silently he passed out of it. But he lived surrounded by friends who had a sincere regard for him, and who did what they could to make him happy, and he died lamented.

"I cannot remember where he came from, and I cannot guess how old he was; but for near thirty years he has wandered over our lawn in sunshine and cloud, and the children who loved to play with him when he first came are now grown men and women, and are scattered up and down the world. He had been with us for a generation, and we mourn for him as a 'link' with the past, though it be but a small one."

The mail of 5th June has brought us the following:—

A LIVING HEIRLOOM.—We are indebted to Mr. A. G. Jefferies, of the Gloucester Arms Hotel, for the following very interesting narrative:—"The interesting account of the life and lamented death of an old friend and summer visitant given by Mr. Take in the *Journal of the Hitchin Natural History Club*, and reproduced in the *Express*, has led me to record a few particulars of another sojourner in our town of the same species. This tortoise is named Jacko, and he has not, I am happy to say, succumbed to the late severe winter, but is, at the present moment, hale and hearty as ever. The scene of the earliest recorded event in Jacko's history is laid at Gloucester. There, about 55 years ago, he was purchased (like most of his kindred who have taken up their abode in this country) from a sailor, by the present owner's grandfather. He was then quite small; he now measures eleven inches in length and ten across. He has lived successively at Gloucester, Derby and Hitchin, and has been treated as a sort of heirloom by the family into which he was purchased, and has descended in a direct line to the present owner. Jacko is a very much domesticated tortoise. His food consists chiefly of bread soaked in milk, which constitutes his morning and principal meal; he is very fond of fruit, also of dandelion and lettuce. He apparently possesses affection for or partiality to some members of the household and will even follow those he is supposed to be fond of, but he is very sulky with strangers. He is the children's playfellow, and is very fond of snugly stowing himself away in a doll's cradle; at other times he prefers to sleep with the household cat, with whom he is on the most friendly terms. Though such an unostentatious creature, he has nevertheless figured to some extent in public life. On two occasions he has during his winter's sleep been exhibited at local bazaars as the "Sleeping beauty," when some of the speculators have seemed dubious as to his claims to this description. At autumn he has always been closely watched, and when his natural inclination to bury himself manifested itself he was placed in some warm and secure corner and covered up, and his burying propensities thwarted. During last winter he was well wrapped up in old cloth, and does not appear to have experienced any inconvenience from the severe weather. Jacko has met with one adventure in the course of his uneventful life. On this occasion he was lost—or, to be more accurate, I ought to say stolen—but, as a result of setting the Town Crier to work and advertising in the *Express*, he was soon after found lying on his back in the yard, having it is supposed, been thrown over the wall, and thus returned to his rightful owner. As a result of this experience he was seriously indisposed for a time, but eventually recovered. Jacko has now been a resident of Hitchin for 20 years."

[Perhaps some correspondent may put together all the authentic details which are available regarding the veteran tortoise, now blind, which has for so many years wandered in the Tanque Salgado swamp and the grounds of Uplands, Colombo?—Ed. T. A.]

ECHOES OF SCIENCE.

According to the annual report of the Agricultural Department on Injurious Insects and Fungi recently issued by the Board of Trade, it has been arranged with the Post Office to distribute leaflets on the attacks of crops in the rural districts. Trials of the plan have been made in the case of the Hessian fly and winter moth; posters showing magnified illustrations of these insects being also

displayed in the country post Offices to enable farmers to recognize them. The report also suggests that washes of sulphate of copper (blue vitriol) should be applied to potato crops not only to check the outbreak of the disease, but to prevent it. Recent experiments in France and Belgium have proved the efficacy of his remedy, as also of sulphate of iron (green vitriol) washes.

Figs.—The old Greeks had a notion that certain parts of the fig were good for digestion, and their observation is borne out by recent investigations. In 1880 M. Bouché pointed out that the fruit and branches of the fig-tree contained a fermentive juice which digested albuminoid substances. Quite recently, Dr. Musci has isolated the digestive principle, which he calls "cradina," after *krade*, the digestive part of the fig. The juice, when filtered and evaporated, and then treated with alcohol, yields a white precipitate, which, on being dried, becomes yellow. Treated with water it swells, and the insoluble residuum, when dissolved in acid or alkali, digests moist fibrin. It differs from pepsin by preserving its digestive properties in alkaline liquids, and from pepsin, in its action not being destroyed by hydrochloric acid. In a neutral liquid it has no digestive power over starch.

An imitation wine is made from figs in France and Algeria, by steeping the figs in warm water and fermenting the liquor obtained. When mingled with a little wine it is difficult to tell it from genuine wine; but M. P. Charles has found that by evaporating it, a residue is left containing a considerable quantity of mannite. As this substance is only an exceptional ingredient in wines, and is never present in anything like the same quantity, it, therefore, becomes a test of grape and fig wine.—*Globe*.

THROUGH SUMATRA.

(From the *Bataviaasch Nieuwsblad*.)

The intended working of the Ombilien coal fields and the construction of a railway to the West Coast of Sumatra has for a long time attracted general attention. People became still more interested when they learned that Mr. Yzerman, the well known Chief-engineer for the construction of the State railway, at the head of a commission, intended to make a journey overland to the East Coast in connection with the possible carriage of coals to that coast. Concerning the long and difficult journey on foot, we were not without fears for the fate of the travellers in this *terra incognita* of our Colonial dominion, and we received the news with joy that the scientific expedition after many difficulties, and with the loss of one of its members, by the treacherous murder of Inspector Van Raalte, had met engineer J. André de la Porte at Langgam in safety. It can astonish nobody therefore that a numerous and intelligent audience assembled at the Hall at the Gardens to hear the interesting information which Mr. Yzerman had been invited by the Administration of the Natural History Society of Netherlands India to give concerning the expedition across Sumatra. The lecture was illustrated by a large map of the explored ground. A branch of the Kwantan runs through the Ombilien coalfields; falls into lake Singkara; leaves the lake on its southern border and winds its way eastward. The object of the expedition was to seek a trace for the railway on the left side of this river. Of the great rivers on the East Coast of Sumatra the Sirk has the greatest navigable length and this river is intended to be made use of in the export of coals. On the 17th Feb. all who were to take part in the expedition were assembled at Si Djoendjaing, the station of the Controller of the united VII. Kotias. Besides Mr. Yzerman there were Mr. S. H. Koorders, forest department, Dr. Van Bommel, natural history, Lieut. Bakhuis chief of the topographical department at Padang, Inspector Van Ranten, Mr. Van Alphen, champion tiger hunter of the Padang highlands and Tuuka of Rau Rau. Eighty coolies were wanted for the baggage, instruments &c. Food, arms and clothing had to be carried, so that the whole expedition consisted of about 250 men. The journey along the Kwantan the lecturer described as one of the most beautiful of the many excursions on

the water he had made in the Archipelago. The steep wall of naked granite, porphyry and oalyx, tinted and shaded in hundreds of colours and crowned with gigantic forest trees were very imposing. The river here has cut out for itself a bed in the rocks from ten to twenty yards wide. High above the head of the traveller gigantic trees rear themselves whose branches meet above the stream which runs beneath their roots. Flowers of the most brilliant colours add life and glow to the exceedingly beautiful and natural scene. A solemn stillness reigns in the regions. It is virgin nature. The beautiful and interesting surroundings did not prevent the attention of the bold travellers being frequently drawn to the dangers which beset them on account of swiftness of the current, and great praise is due to the Malay boatmen of Salahé. Fallen trees blocked up the spaces between the rocks. This was only a foretaste of the difficulties which the voyagers were afterwards to meet. Mar Mokko-mokko the goods were taken out of the boats and brought overland past the waterfalls and currents to be placed again in the boats lower down. The place where this happened is called Solek and here a tunnel of 1800 meters will be necessary, which can however be built in two sections of 1,350 and 450 meters. Having arrived at Ambatjong a camp was formed and some days' rest were indulged in. The reception by Tuanku Kadi Radja was very hearty. A flask and a *stendang* were accepted as valuable presents by one of the chiefs which shows the primitive condition of the people in these parts. Labo Ambatjong is one of five districts which in name recognize the authority of the Radja of Basorah who has his residence at Tjarantel on Kwantan. In this region called the Kantau the authority is said to be merely nominal and in the district Luhu Jambi and Taloe which are hostile, the Radja has nothing to say. On account of information from Padang according to which the Taloes had declared themselves to be under the authority of the Radja of Basorah, Controller Rengat went to Indragiri to ask the chief for his co-operation and approval of making surveys for constructing a railway. These were granted and the travellers went there but they were firmly forbidden to enter the land as they wanted nothing to do with the *Blandis*. There is now some ground for this distrust. The authority of the Government in these regions is very weak. Districts under Dutch authority in case of war against independent provinces always ask the Controller for assistance and he invariably refuses for some reason or other, generally from inability to grant it. The auto Malay sees this at once and is *malu* to seek our support. Another reason, said the speaker, for hostility to us is the *ladies*. The women contrary to the custom in other Malay countries have an extraordinary amount of influence over their husbands and they make full use of it. While in other district, the man is spoken to as *angkau* and the woman as *kau*, the males in Taloe are disdainfully addressed as *kau*. A Malay legend gives the following as the cause. Once upon a time some men and women were working in a *ladang* when a gigantic tiger sprang roaring into the midst of them. The men instead of uniting to offer a courageous resistance took to their heels and left the women and children in the lurch. Thus came the men into bad odour. These people gave proofs of their hostility and Mr. Yzerman to avoid political questions was obliged to turn aside so as not to pass thro' their land. On the second of March this party left Logoi di Rambu. Messrs. Yzerman, Bommel and Koorders were in front, then came the coolies who formed a long train with Mr. Bakhuis behind. A few paces off came Messrs. Alphen and Ranten one armed with a Boanmont rifle and the other, with a revolver. Peaceful and without a thought of insecurity the journey was continued. Wherever we had been we were received in friendly manner and we had no suspicion that this day would have so sad an ending. Suddenly we in front heard rifle shots echoing thro' the jungle. Not suspecting any evil we continued calmly on our way, then cries from the coolies made us think somewhat was wrong. Again shots were heard and the coolies bolted. Those close behind us threw away their

bundles, ran past us followed by the others all frightened and panic-stricken. Thousands of enemies had attacked the rear of our party and had overthrown all those who did not take to flight. We did not try to rally the coolies; it would have been useless. Followed by some of the most courageous including a Javanese mandor we retreated to the rear and met Bakhuis. He had heard shots and turning round saw Van Raalten staggering out of the jungle and after going a few paces he placed his hand to his head and fell down. Van Alphen had seen Bakhuis fire at some figures that suddenly came out of the wood and then disappeared again in the thicket. Rifle fire was no use here. It was a case for calm reflection and parley with the enemy if possible. What could we, a handful of Europeans, do against such numerous enemies on ground known to be completely hostile. Do not shoot, was my order. These were the most painful moments of the journey and they will always remain in my recollection. The moment has come to express a word of sincere thanks to my fellow travelers. My time has been so much occupied that I have not been able to do so before. Then I learned to know them, not only as men inspired by a holy love for science but as men who in the hour of danger can be implicitly trusted. Whilst we stood there we decided on the one hand not under any consideration to take to flight and on the other to sell our lives as dearly as possible. More shots were fired and the Javanese mandor by my side fell mortally wounded. We found Van Raalten with a bullet in his head and a *klewang* wound on his body, lifeless on the path. The Malays had disappeared. All along the track goods that the coolies had carried were strewn about. A portion of the baggage had fallen into the hands of the robbers. Robbery, the Malay ideal, was the object of the attack. By degrees the coolies were persuaded to take up their loads, and we placed Van Raalten in a simple grave near where he was murdered. The expedition between Logei Ramban and Luggam met a number of natural obstacles. The land between Kampar and Kwanan is not as was supposed a series of swamps but just hilly and with comparatively little water. The formation of the land between Siak and Kampar differs little from that between Kwantan and Kampar only that it is more swampy in the neighbourhood of the Siak river. The way through the Sumatran woods in high situations is not difficult. They consist principally of upright trees of three feet or more in thickness and fifty feet high under which there is a thin lean undergrowth of young timber that has not had sufficient air and light to make it flourish properly. Here ten or twelve men armed with knives can easily cut a path for the bearers. Where, however, a thick growth of *alang* or what is worse extensive swamps lie in the way then difficulties begin. In the swamps a sort of root tree grows which spreads out a network of roots which catch the feet of the exhausted traveller as in a trap. Then the experienced catch hold of a branch, a creeper which offers support and his skin and flesh is torn by the saw-shaped bent, outting thorns which are completely hidden from the view by thick leaves and which cause intense pain. Besides these difficulties there are those from the animal world. The wasps in the jungle and *alang* fields, when the unwary traveller sets his foot on a nest of them, spring up, and he then experiences the painful consequences of their anger on his face, neck, and other bare parts of body. The horsefly sometimes comes in swarms and is very troublesome. But the worst of all is the ant. The ant, says the proverb, belongs to the east; and this is true with regard to Sumatra. All varieties of this insect are found in the woods, and fields; from the tiny black one that bites and torments the victim whilst he seeks in vain for him, to the gigantic red one. The population in these regions do not regularly cultivate the land and they are constantly on the move. Poverty rather than affluence is met with, as is usually the case in thinly populated lands. The Malay, however, is not discontented with his lot. We saw that the men as well as the women we met had intelligent friendly faces. The men have a comic appearance because they stroke upwards the few small hairs that adorn their upper

lips into a pointed moustache. Days passed without the travellers meeting a single human being. Deer and pigs were comparatively scarce in the bush. On the other hand there were numerous traces of pelyderms such as the elephant and rhinoceros. There were traces of bears' claws in the trees, so that these animals must be there in comparatively large numbers. To find the way in these almost limitless unfrequented woods is most difficult especially for the Malay who has no compass. The half cutting through branches on their way is a help to them and these bud out again and in this way serve as sign posts for years. At Luggam on the Kampar river on the 17th March the expedition met Engineer La Porte from Siak. On the 31st of that month the whole party arrived at Siak. Of the coolies there were twenty behind on account of sickness and desertion. The speaker finished his highly interesting reading with the wish that the iron horse should speedily break down the barrier which now separates the East Coast from the West Coast of Sumatra which will bring welfare and civilization to the impassable woods and inhospitable lands.

"HEMILEIA VASTATRIX."

PREVENTION IS BETTER THAN CURE.

BY WILLIAM PRINGLE, M. S. C. I.,

LATE AGRICULTURAL CHEMIST TO MESSRS. MATHESON & CO. IN COORG.

(Under special arrangement for publication in the "Ceylon Observer" and "Tropical Agriculturist")

Coffee leaf disease, *Hemileia vastatrix*, has produced such dire effects on the coffee of Ceylon and Southern India that most of your readers are quite familiar with the name and a brief outline of the life history of this deadly parasitic fungus will probably prove interesting. Those who wish for fuller information are requested to carefully read Mr. Morris's and Mr. Marshall Ward's reports.

I have carefully gone over the ground traversed by the latter gentleman, and can fully corroborate his statements.

When a field of coffee is attacked by the disease, the bright glossy green of the leaves is changed to a dull yellow, and on examination the under surface of the leaves is seen to be covered more or less with an orange-colored powder. This powder is composed of myriads of spores of the fungus *Hemileia vastatrix*. One of these uredo spores, sown on the under side of a leaf of a tree, if the conditions of light, heat, moisture, and texture of the epidermis be suitable, will in ten to twenty hours germinate, and penetrate the stomata of the leaf; if the medium on which it is planted prove unsuitable it dies, or may remain inert for months. On a coffee leaf Arabian species after germination in about three to five days a mycelium is formed, consisting of microscopic tubes. When these have absorbed all the food contained in the cell in which they were first formed, sucking organs are developed, which penetrate the neighbouring cell walls, feeding on the juices of the plant. As the cells' contents are removed and taken up by the fungus, so the mycelium extends, pushing its suckers into the surrounding tissues; when the cells are emptied a yellowish spot appears, generally visible about two to three days after the parent spore is planted.

The rust patch is formed in about two to four days after the appearance of the yellow spot as a rule when the conditions are favorable. If the weather is unfavorable or the medium on which the spore was sown unsuitable, the development is greatly retarded, and a yellow spot may show on a leaf for two or three weeks before any spores are shed, or they may not form at all.

The rust patch is formed when the spores are forced up through the stomata. As the mycelium spreads, and increases in size, more spores are developed, and the patch of rust grows larger, radiating from a central point.

As the work of destruction is carried on within the leaf by the mycelium, it is quite evident that remedies applied after the spores appear on the epidermis of the leaf are useless; they must destroy the tissues to reach the foe within. Any agent to be of use must be on the leaf before the spore finds a resting place on it.

When experimenting on the development of the spores on a coffee leaf, I took a clean seedling and raised it in a case prepared on Tyndall's method, with the result that I got a plant free from leaf-disease growing in sterilized soil. The spores only grew where planted on the leaf, nowhere else, and Mr. Marshall Ward's results were fully borne out. The disease is not constitutional: the spore of the parasite must be deposited on the leaf before the disease can appear.

A weak tree suffers more than a strong one from the loss of its leaves; and a tree weakened by injury to its roots, due to removal of the surface soil by wash, manotie digging, or other causes, recovers less rapidly, and if the attack of leaf disease or succession of attacks are virulent will in all probability succumb. The lower the vitality of the tree attacked the smaller its chance of recovery.

A half-starved coolie readily falls a victim to fever, cholera &c., while if well fed he more easily resists the attack of disease; so it is with the coffee tree.

The conditions most favorable to the development of the spores are a close, steamy, hot, stagnant atmosphere, with a subdued light.

Heavy dews followed by hot days, if a dense shade is over the coffee, aid in the fructification.

As a rule leaf disease is bad in South Coorg twice a year: just after the early rains, and during the autumn showers. In the hot weather we are practically free from it, though I have found the disease spots and rust patches in every month of the year.

Shade under which the coffee of South Coorg is grown affects the disease in two ways.

It acts as a wind screen and retards the passage of the spores from one estate to another. If the coffee is one continuous sheet the disease may start at one corner of the estate and roll right over it when the climatic conditions are favorable.

I have visited an estate on the first of the month, and though leaf disease was to be seen, it was not suffering to any extent; fourteen days after the estate was red from end to end, and by the end of the month it had resumed the appearance presented at the beginning.

This estate suffered from these periodical attacks, which always began at one corner, and swept over the estate in regular progression.

Further examination showed that it was not the only estate affected in this way; and in every case the starting point of the attack was where the shade was thick, with damp and sour ground below. The air was, especially in the early morning laden with moisture, with often not a breath of wind. As the sun rose, the best possible conditions for the development of the fungus came into play.

Here shade did more harm than good; being too thick it prevented the free admission of light, conserved the moisture to an undesirable extent, and aided greatly in the production of the moist heat necessary for the germination of the spores.

Under the circumstances the course to be pursued was first to render the conditions unsuitable to the fungus, by regulating the shade, and draining the land; then apply the remedies.

The reason why the lower leaves of the tree suffer most, is that the great resting-place of the spores is on the ground, on the dead and dying leaves resting thereon; the coolies pick up spores and dust as they walk through the coffee, and the bulk of the spores find a resting-place on the lowest leaves. These are shaded by the upper branches and intercept more of the moisture evaporated from the ground so that in general there are not only more spores on the lower leaves but the closer they are to the ground the more favorable the conditions are for the development.

Unless the ground and the jungle trees are treated, to say nothing of the neighboring estates, it will be impossible to eradicate leaf disease.

But an estate can be kept practically clear of the pest by one application to the ground and two to the leaves per annum.

In Franco remedies are applied to the vine four times per annum with great success. The work is not expensive; only labour must be there to do it at the right time.

The *Hemileia vastatrix* or a fungus so closely allied to it that I can see no difference between them is to be found on at least three jungle trees. Unfortunately I know next to nothing of botany, so cannot classify them. It was on the goni (*Ficus mysorensis*?) that I first found the spores: whether these are the uredo spore or the second sort of spore which prefers another host I am not sufficiently well up in cryptogamy to determine, but the spores taken from the goni and sown on the coffee leaf developed there.

I had a few failures, in transferring the spores from the coffee to the goni, but on the whole, results were satisfactory. The atty (*Ficus glomerata*) when a young plant was taken could also be infected. If the leaves are old, the yellow spots may show in the leaf, with but very few spores being formed.

Liberian coffee, which has a much tougher leaf than the Arabian, displays much the same characters as the atty and goni.

The damage done by the *Hemileia vastatrix* is entirely that of depriving the tree of its leaves. You can make a coffee tree sick by varnishing its leaves on the under surface and so preventing its breathing; consequently in selecting a remedy care must be taken that it does not clog up the pores of the epidermis. It would do more harm than good. Stripping off the diseased leaves ranks in the same category.

A tree must have its leaves which are its lungs in good order or it cannot develop its fruits. If all the blossom that appears would set, crops of from five to ten tons per acre would be common. As a matter of fact only from one or two to ten per cent set, and all of that does not come on.

The true use of a manure is to enable the tree to set its blossom, and to assist in the development of a healthy bean. My experimental plots being systematically manured were able to set a larger proportion of the blossom than the estates, though both received the same work, the only difference being in the manures and ———.* Though pruned and handlo down to the level of the estates, they had a finer show of leaf and wood, and recovered from an attack of leaf disease more rapidly.

The results from the estate where leaf disease was worst, taking the crop of 1887-8 as the basis and stating results as percentages on that, for both plots and estate, we get the following result:—

Year	1887-88.	1888-89.	1889-90.	1890-91.
Estate	100	69.1	34.2	8.5
Plot	100	90.9	239.5	36.3

This shows the value of steady systematic manuring broadcast annually, and this year the plots have a splendid crop on them.

It requires time, patience, and careful observation to get reliable results, and the results to be of value must form a series obtained by steady systematic work. Not knowing how the various manures would act on the coffee tree I began with only small plots of 3,200 trees, or rather the space occupied by that number when the estate was originally planted. Each manure acted on two plots of 100 trees each, and the results individually taken are not conclusive. Therefore I had to take for comparison the aggregate results, including good, bad, indifferent and the unmanured plots for comparison with the estates, which in most cases did not receive the manures I recommended, owing to failure of the supply of fish and other causes.

Now as to preventative measures. Steady systematic manuring annually holds the first place; drainage is in some cases quite as important, and the careful regulation of shade render the conditions under which the coffee is grown suitable to it, and unsuitable to the fungus; then special remedies can be successfully applied.

* A word which cannot be made out.—Ed. T.A.

Six months ago I did not know how the practical application of remedies was to be managed. Sponging the leaves over took from 15 to 20 minutes per tree, spraying with a syringe took from 5 to 10 minutes and was not thorough. Laboring under this difficulty I did not consider that any practical good was to be gained till this point was settled. For as Mr. Ward said it is not the most difficult thing to find a substance to destroy the fungus, but it was somewhat difficult to comply with the other conditions laid down, but I managed over that. And in February last two spray machines were sent from England by Messrs. Matheson & Co.: these fulfilled all the conditions necessary for practical work.

All that is now required is to test the remedy and method of application on a wholesale scale.

I have been engaged in practical work, ever since I left school, and I can honestly say that leaf disease is preventible by practical measures, if there is labor to carry through the work at the right time.

WILLIAM PRINGLE, M.S.C.I., Late Agricultural Chemist to Messrs. Matheson & Co., in Coorg.

WYNAAD PLANTERS' ASSOCIATION.

Proceedings of a general meeting held at Vayitri Jubilee Hall, 3rd June 1891.

LEAF DISEASE.—Revonue.—“The Government considers that it would be very desirable to comply with the request of the Wynaad Planters' Association (that Surgeon Major Barclay be sent to the coffee districts of Southern India on the special duty of investigating *Hemileia vastatrix*) and the Government of India will accordingly be addressed.”—Recorded with satisfaction. Read Honorary Secretary's letter of March 10th to Professor Galloway, Bureau of Vegetable Pathology, Washington, to which no answer has been received.—Read letter from Mr. Pringle, M.S.C.I. offering his services as a scientist and analyst: the Honorary Secretary was instructed to thank Mr. Pringle, and to inform him that the proposal to give a large reward for a practical cure for leaf disease was still under discussion.

TEA.—Mr. Hockio stated that five Essays had been received. Resolved:—“That Mr. G. L. Yonge be requested to act as Judge of the Essays.”

THE TEA MARKET AND VARIATION OF PRICES.

SIR,—Every year, when the tea market is low and prices poor, one hears a great deal said about the poor quality of the tea sold, and only in one or two cases are good prices realised. Now it appears to me that a good tea has no chance at all if sold when the market is low, as I will show. In January I had in the factory between 8 and 9,000 lb. tea, but, being unable to send it all forward in one invoice, I divided it as equally as I could and sent the first lot forward to London by the 8th of the same month valuations on samples giving, for Broken Pekoe 1s 1½, for Pekoe 1½d, Pekoe Souchong 9d, for which I got—for Broken Pekoe 1s 4d, Pekoe 1s, Pekoe Souchong 10½d, average 1s 1½d. Through one delay and another the second lot did not go forward to London before March. This was valued in Colombo at a higher figure than the other half (though the same make)—Broken Pekoe 1s 3d, Pekoe 1½d to 1s, Pekoe Souchong 10d, while the prices realized were Broken Pekoe 10½d, Pekoe 8½d, Pekoe Souchong 8½, average 9d, the same teas from one invoice fetching 1s 1½d and 9d average.

June 24th.

CORRESPONDENT.

—Local “Times.”

* And Money.—Ed. T.A.

THE CHOCO is a new plant or vine well known in the island of Samoa, which is creating great interest in Santa Barbara. The fruit weighs on the average about three pounds and has the flavor of a chestnut. It ripens in about 90 days and has been known to grow to weigh 20 pounds.—*Rural Californian*.

TEA IN JAPAN.—*The Japan Weekly Mail* of 13th June says:—

A large business has been done in Tea, and settlements to the 10th instant total 132,323 piculs. The leaf now being mostly handled is said to be not quite so good in cup as the same grades last season. Prices are well maintained, and second pickings are coming in.

The same paper in its issue of 20th June says:—

The Tea trade has not been quite so active, but prices have been well maintained. Second crop leaf is now in full supply, and total settlements to date are 20,000 piculs more than at same period last year.

THE COLONY OF THE LEeward ISLANDS.—The text of Mr. Morris's lecture on these islands has just been printed in the journal of the Royal Colonial Institute. It comprises a description of the natural features of the islands and their agricultural resources. As in the case of agriculturists nearer home, the colonists have manifested a tendency to put all their eggs into one basket, and with more or less disastrous results. Thanks to the initiative of Kew, and the energy of Mr. Morris, “botanical” stations, which should rather be called agricultural stations, have been instituted for the purpose of introducing and distributing tropical and other plants likely to be of economic importance and suitable for cultivation in particular districts, such as Coffee, Tea, Cane, tobacco in various forms, Cinchona, spices, fibre-plants, and so on. A great federation of botanical and agricultural stations, with Kew at the centre, has been the ideal of successive directors, and now the ideal is being realised. Perhaps in the future the West India Islands, or other suitable localities may be utilised as nurseries for Orchids and other tropical plants, whence the home market may be supplied, somewhat as the propagating houses at Kew furnish the decorative plants for the show houses.—*Gardeners' Chronicle*.

JAVA CINCHONA ESTATE DIVIDENDS.—The annual general meeting of shareholders in the Java Cinchona Planting Company, “Melattie,” was held in Amsterdam on June 3rd. A dividend of eleven per cent was declared for the working of the year 1890, while, in addition 2,000f. was written off for depreciation of buildings, 3,000f. carried to the reserve fund, and a balance of profit of 1002-54f. carried to now account. The name “Melattie,” does not occur among our list of Java estates. There is, however, a Goenoeng Melati estate, which is one of the best in the island, and produces an equivalent in bark of 4,000 to 6,000 kilos. sulphate of quinine per annum. It does not follow by any means, however that the dividend was not obtained from produce other than cinchona.—*Chemist and Druggist*, June 12.

THE NAME OF CEYLON and of its chief products, especially tea,—has probably been made known more widely through the *Tropical Agriculturist* than even through the Tea Fund or its agents. We got letters from the most out-of-the-way corners of the world in appreciation of the T. A. and its contents. One of the latest is from the editor of “The Telegram,” Colon, Central America, who thinks so highly of the periodical and of its usefulness to the agriculturists in his State, that he has begun advertising it without waiting for our order! The filing of the *Ceylon Tropical Agriculturist* in the Agricultural Department, Washington, makes reference to it not infrequent in the official papers which are issued by the Secretary to all the States of the Union. And so the name of Ceylon and its planting enterprise becomes known far and wide.

THE TARE WEIGHT OF TEA AND CEYLON TEA CHESTS.

We recur to this subject in order to make it clear what was done last year. The action of the Ceylon Association in London was then sought by our local planting representative body with the object of the removal of the cause of complaint. The letter addressed by the Secretary to that Association in reply to this request stated that after the fullest examination of the matter, which included the questioning of several of the leading Ceylon men in London, it was not found that the assertions as to undue deduction, emanating from this side, were borne out by the experience of those from whom evidence was obtained from home. That letter, however, proposed to our Planters' Association that a test case should be obtained. It suggested that a Commission, to be appointed by the last-mentioned body, should personally supervise the weighing and packing of a considerable consignment of our teas; that these should be sent home in the ordinary course and that parties to be nominated by the London Association should in the same careful manner supervise the weighing of the shipment when received in the London Docks. Now it seems to us that no fairer opportunity could be offered than this of ascertaining how far the complaints made were well-grounded or the reverse. Yet it appears to be the fact that no notice whatever has been taken of this suggestion. Must it not be naturally concluded therefore that the representatives of our planting interest were satisfied—that in the majority of instances at all events—substantial justice was done to Ceylon planters in this particular matter by the Custom authorities in London?

The London brokers and merchants go further and allege in effect that the whole mischief is due to neglect on this side of the Customs regulations with regard to weighing and packing here in Ceylon. It is pointed out how completely the fractional parts of a pound are ignored under those regulations. Thus if a chest turns out say 49 lb. 15 oz., it is reckoned as 50 lb. gross. Similarly, if a chest turn out but 49 lb. 2 oz., it is still reckoned for tare at the same weight. So in the one case the shipper would lose but one ounce on the tare weight, while in the other he would have to sacrifice 11 ounces. The object of our planters should therefore be, to see that their chests are of weights as close to, but under the full pound, as may be possible. It is alleged for the defence that in an exceedingly large number of instances of shipments from Ceylon this point is altogether overlooked: that in fact the whole burden of blame for what is complained of rests upon those on this side who carelessly or ignorantly overlook the conditions upon which their shipments will be dealt with by the Customs authorities at home.

We do not suppose that the latest suggestion made from London can affect this, but we should like to know if any of our planting community have had experience of the capacity for change of weight of ordinary tea chests under varying conditions of atmosphere. Mr. Cameron of the Eastern Estates and Produce Company is of opinion that a not inconsiderable part of the difficulties as to the tare weight of tea recently complained of, has been due to the changed weight of the tea boxes used here after the passage to London. Mr. Cameron thought this might amount to as much as half a pound; and he unsparingly condemned a large number of the packages in which our tea is sent home, as being of such unsuitable wood that damp in the hold of the vessel is readily absorbed by it and the tare

weight thereby most sensibly affected. Now as we have shown a very much smaller increase of weight than half-a-pound per chest would very injuriously affect the tare weight and the consequent burden to be borne by the planters. The advice from Mincing Lane is to weigh as close to the even pound—but below it—as possible for tare weighing, and we are advised to allow a margin of two or three ounces only. But if during the voyage home, a chest increases, owing to the absorption of damp, as much as half-a-pound in weight, that margin would be passed and—hey presto!—the Customs officials would tare the unfortunate one at the additional pound. The use of thoroughly seasoned wood for the chests will of course be recommended as the obvious remedy; but where is such wood to be obtained? No doubt it is quite within the power of our planters to accumulate a stock of wood and season it; but then, unfortunately, a very large proportion of our country-grown woods will not stand the process of seasoning without developing faults which render the boards cut from them wholly useless for the manufacture of tea boxes. No doubt Japan boxes have the advantage here and as a matter of fact it would be interesting to know if the complaints about loss of weight have all been confined to boxes of country-made wood? Some hopes were entertained, we believe, that the Stanley-Wrightson patent chests might not be affected by the damp and resultant increase of weight, but from all we hear this has scarcely proved to be the case. We really think this difficulty about absorption of moisture during voyage might well be employed as an argument towards inducing the Customs authorities at home to reconsider their present inaction with regard to their minute about weighing to the half-pound instead of to the pound. If this obstacle respecting the variable weight of tea chests cannot be got over, it is exceedingly hard that, despite all precaution by the planter, he should be mulcted in a pound weight as the result of a circumstance over which he can exercise little or no control. We have been told that the China teas imported give no trouble with respect to this question of tare, but that is solely because no China teas are bulked after arrival in London. There are very many objections to metal chests; but certainly this uncertainty about tare weight could not apply to them, and this might be a gain compensating for many minor disadvantages appertaining to their use.

VISIT TO JAMAICA.

Taking advantage of Mr. Plant's new Jamaica line from Tampa, I have just paid the island a two weeks' visit, chiefly for the purpose of gaining new ideas of methods of culture and propagation of tropical fruits. I think my experience is on the whole very flattering to our own State, though the object of my visit was not realized.

I found a truly tropical island with a deep, fertile soil, provided with tillable slopes, elevated enough to admit of the successful growth of apples and peaches, where a paternal government at a heavy annual outlay has for many years kept up extensive experimental gardens and nurseries presided over by talent from England, with trained and educated horticulturists for foremen; and still they are far behind us in methods of propagation and varieties. They still inarch the mango in the slow unsatisfactory way introduced from India. They plant only sweet seedling oranges and never bud. The peaches and apples of

slavery days have been allowed to die of neglect and forest fires. With an abundance of water-head in mountain streams they allow fertile plains to dry up and remain sterile for want of irrigation. But the Boston Fruit Company, represented by their founder and president, Capt. S. D. Baker, the banana king (as the natives call him), are making things move on the north side, and with a progressive governor and pushing earnest chief of their botanical department, bid fair to revolutionize Jamaica in a few years.

Most of the soil is stiff red or brown clay and but little of it seems suited to pineapples, while but little seems suited to bananas. We see them growing on the steepest hill-sides, so steep that the top of the stalk is nearer the ground horizontally than vertically. A large portion of the available land was all in sugar cane before abolition, but since then, though the slaves were all paid for, the planters could not pay running expenses, hiring the lazy freed-men; and gradually all the estates were turned into pasture or abandoned. The freed-men preferred to strike out for themselves and be independent, so they squatted here and there and have lived a lazy, hand-to-mouth existence, such as their forefathers enjoyed in Africa ever since. The paternal government only interferes with this for the first few years of their lives, obliging them to acquire a good common school education. These few years of enforced labor, I presume, are sufficient to reconcile the colored man to a prolonged rest during the balance of his life.

The Boston Fruit Company have acquired some 20,000 acres of these old sugar estates and are gradually reclaiming them for bananas and coconuts. They run steamers three or four times a week to Boston, making the run in five to seven days, and have never failed to carry their vegetables in better order than our railroads usually do. This year, for the first time, they secured the services of a market gardener from the North, and he has been experimenting with ten acres in vegetables as a trial. His tomatoes yielded almost as they would at the North, when they were not dried or drowned out; and his cucumbers seemed to be quite free from insect enemies and yielded much better than with us. Mango trees line the roads and are as abundant in the woods and fields as native forest trees, while coffee and cocoa trees form the underbrush everywhere in the abandoned estates; and here and there an enterprising colored family squat and make their living gathering and selling the fruit of these wild trees, which, however, they never cultivate. The all-spice, *pimenta officinalis*, is a native forest tree and the logwood, a leguminous tree, is the regular second growth timber, which, in time, with *lignumvita* and cactus, takes possession of old fields. A fair quality of tobacco is raised in the valleys by Cubans; Liberian coffee a hardier, more prolific and superior variety, is being introduced; also the coconut of India, which is used on account of its large amount of caffeine to give strength to chocolate. Nutmegs and cinamons are being tried also, but the great crop is bananas. From 10,000 to 15,000 bunches per day leave Jamaica for the States, three fourths of which are either carried or supplied by the Boston Fruit Company through the banana king, Capt. Baker.

The scenery is grand. A midrib of volcanic mountains serves as a background for the views inland on the east end of the island, towering to upwards of 7,000 feet. Innumerable ranges of foot hills, wooded to their summits, are intersected by crystal streams, cutting deep gorges through their rocky sides, all draped with luxuriant tropical foliage. Tall tree ferns wave on shaded slopes

while graceful coconut and royal palms raise their majestic heads proudly against the sky on mountain tops thousands of feet above the sea, which rolls "deeply, darkly, beautifully blue" at their feet. Tufts of feathery bamboo, like bunches of ostrich plumes, wave on every slope and plain, tall as the forest trees and indescribably soft and graceful; while large silk cotton trees with their ponderous, root-battered trunks and great straggling limbs seem to writhe and stagger beneath their burden of throttling vines and parasitic orchids. Aroids, climbing plants with the leaves of a caladium and stem of a sugar cane, climb to their summits and envelope the tree with long, white, rope-like roots, half an inch in diameter, which spring from every joint of the stem. When you add to these orchids with leaves like bananas, the efforts of the tree at foliage seem very insignificant and secondary.

Coolies and Chinese are found occasionally, and each one does the work of three negroes, though not nearly as large and muscular. Some of the ootaroons and quadroons make good foremen and under bosses as well as clerks and book keepers.

The government levies an apparently indiscriminate duty upon all imports, a tariff for revenue only, so far as I could learn, taxing flour \$2 per barrel, though they can raise no wheat, but strange to say, entering potatoes free! With the revenue thus collected splendid macadamized roads are kept up, abundance of excellent water supplied to every town and village, excellent nurseries (which supply trees at cost), good schools and efficient police force maintained. Enough money is left over to pay the Englishmen who exile themselves here to fill the higher government offices handsomely for their services; and if the bulk of the colored population is poor, they are happy; poor because they are lazy, and happy because they can be lazy.

Melbourne, Fla.

JOHN B. BRACH

—Florida Dispatch.

Cinchona cultivation is rapidly progressing in India though unfortunately the tree will not grow with any prospect of commercial success in any spot north of Lower Bengal, the Peninsula and the Straits Settlements. An American paper recently gave a graphic account of the plantations in Java which are ruining the Bolivian industry, and from this it appears that at the age of eight years the trees are ready to strip, or if the owner is hard up, as is usually the case, part of them may be utilised sooner; and young plants put in their places. In some sections it is customary to remove from each tree about a quarter of its bark every year, but in others the tree is cut down to the ground, its trunk and large limbs are peeled, and the sunniest branches carefully scraped clear of the leaves. An eight-year-old tree yields from twelve to fifteen pounds of bark. If the peeled-off bark happens to get wet it loses much of its alkaloid quinine, hence every planter has to build ample sheds in which to dry it. There are said to be no fewer than twenty-one varieties of the quina tree, some worthless, others ranging in the amount of quinine contained in the bark from one half per cent to seven per cent. The buyer must know his business, for if not an expert he is likely to be badly sold. The "gold brick" swindle has not been so often perpetrated in the United States as that of selling for cinchona bark the worthless bark of some other tree. A well known dealer of La Paz, who ought to have known what he was about after years of experience, recently lost \$150,000 at one fell swoop on a ship load of bark supposed to be cinchona, but which, when it arrived at the English market, turned out to be a species of oak good for nothing at all. The only way to test the bark is by testing it. That which gives out a better taste immediately on being taken into the mouth will yield a comparatively small amount of quinine, while the best must be chewed before the quinine taste is apparent.—*Indian Agriculturist*.

EMIGRATION OF THE UNEMPLOYED HIGHER CLASSES.

[An old Ceylon Colonist and friend—now of North Borneo—writes as follows in the *Field* of June 6th.—Ed. T. A.]

Lord Dorby, when speaking at Liverpool, on Dec. 29th, on the subject of emigration said that England cannot find employment for its increasing population. This applies to the rich as well as to the poor, and I would like to say a word through your columns to the unemployed sons of the richer classes in favour of a planter's life in British North Borneo. As I spent thirteen years in the coffee and tea districts of Ceylon, and have taken an active part during the last eight years in the planting industries of British North Borneo, I may reasonably claim an intimate knowledge of my subject, gained by twenty-one years' practical experience of tropical planting.

British North Borneo is rather larger than Ireland, and is situated at the northern extremity of the great island of Borneo, in the same latitude as Ceylon, which it much resembles in climate, but its hills are much higher, and cover an area probably five times as large as the central, hilly, province of Ceylon, and, what is of chief moment to the planter who desires cheap transport, good soil is obtainable near the sea—soil that has been proved to be suitable for tropical plants like tobacco, coffee, cocoa, pepper, gambier, sugar, &c.

Tobacco planting is being prosecuted on a very extensive scale, and the companies engaged have a nominal capital of about six millions sterling. Tobacco is an annual, and the accounts of the 1890 crop (amounting to 15,000 bales), which was cut before the rains began to fall in December, are very good, and indicate that the troubles connected with new enterprises are being overcome, and those who are most capable of judging anticipate a great future for the silky leaved tobacco grown in British North Borneo, which now obtains as much as 3s. per lb. for cigar wrappers, as compared with 8d. per lb. obtained by American tobacco, which is used as cigar fillers. The amount of land taken up by the tobacco companies on the low alluvial flats on the great and small rivers is about three quarters of a million acres, which afforded a reason for raising the price of land intended for tobacco planting to 6 dols. (one pound sterling) the acre. For other products than tobacco the price is still 3 dols. (10s.) the acre.

In Sumatra, where wrapper tobacco is cultivated, the price of suitable land is very high, and the Netherlands government has lately limited the sale of land in its colonies to Dutch subjects only.

Coffee appears likely to be the next product to be planted in large quantities in British North Borneo. The price for coffee is high, and the coffee brokers inform me that, as far as they can judge, they see no reason for a fall. In 1882, a coffee planter from Ceylon, Mr. T. S. Dobree, visited British North Borneo, and reported that the new colony was suitable for coffee, and that, in his opinion, it might become the greatest coffee producing country in the world. The island of Borneo is surrounded by the coffee-exporting countries of the Philippines, the Indian Peninsula, Java, Celebes and Sulu; but I have no knowledge of coffee exports from British North Borneo until 1887, when coffee and pepper appeared in the export return. Pepper, encouraged by high prices, is now largely cultivated by the Malays, who formerly supplied the markets of the world, until the cultivation of pepper was strangled by the exactions of the sultans; thanks, however, to our English rule, the agriculturist in British North Borneo can now pursue his vocation in peace.

Coffee has hitherto received little attention, cocoa being the rich Malay man's favourite beverage, and thriving well without much trouble; but enough coffee can be found to warrant the statement made by Mr. Dobree, that British North Borneo is very suitable for coffee growing. Since then we have learnt more about it, and a small pamphlet issued by the British North Borneo Company, in August 1890, gives details of the

steady progress, since 1882, of the cultivation of coffee, which has lately found favour among the immigrant Chinese who began to settle near Kudat, in 1883, and now number over one thousand. The coffee in the experimental garden at Silam, opened by the company in 1882, yielded 76 cwt. in 1887 from about six acres, and continues to bear well. Those who have no knowledge of coffee planting will understand the meaning of the above figures, when I say that at present prices the profit per cwt. on crops such as the above should be quite 30s. per cwt., and the cost of bringing coffee into bearing should not be more than £20 per acre, taking the cost of land at 10s.

When I was in Ceylon in the "seventies," good land was considered cheap at £10 the acre. The British North Borneo Company make only one charge for land, [now 10s the acre] and give a 999 years lease, which compares very favourably with land in Sumatra and India. In Sumatra land is leased for seventy-five years, and at Darjeeling for thirty years, on payment of a premium and a rental, and in both places the rent increases up to the fifth year, when it amounts to about sixteen pence per acre.

Having lived in British North Borneo, and being about to return for a further stay, I feel that my recommendation of emigration to this new and comparatively little known country is worth a hearing by those who like an outdoor life. At present there are about one hundred Europeans engaged in planting in our territory, among whom the proportion of married men is steadily increasing, and the ladies tell me they like the life. Comforts are obtainable by those who can manage properly, and have the wherewithal, which means about £15 a month for a bachelor, and £25 for a married couple, though, if necessary, it can be done upon less, and I have known men to live upon about half the above.

To show how the country is progressing, I quote the following returns for 1881 and 1889, in which time the imports and exports rose from £25,000 to £400,000; and the revenue from £3,000 to £80,000 sterling. For 1890, the returns of trade will be about thirty per cent more than those of 1889, and the statement made that British North Borneo is advancing by leaps and bounds is not out of place, as the yearly returns show a steady annual increase of over 30 per cent upon each preceding year. The commercial importance of British North Borneo has lately received acknowledgment by its admission into the Postal Union.

The laws are based upon English colonial usage, and have chiefly been adopted from those ruling in the Straits Settlements and British India. The distance of the territory from England is about thirty-five days steam, and the cost of a first-class passage varies from £50 to £70. Should any one desire to make a visit, good hotels will be found at the two chief ports, Sandakan and Kudat, and some sport with deer, cattle rhinoceros, and elephant can be had for the seeking.

The reason why I specially recommend coffee planting as a means of employment to some of our unemployed wealthier classes is, because it is within the means of men with from £2,000 to £5,000, and because coffee appears to have found a natural home in the climate and soil of British North Borneo, and promises to give very large returns.

The cultivation of cocoa, gambier and pepper can be combined with that of coffee, the same soil being suitable. I am particularly desirous of seeing gambier planted. I am told by the Mincing-lane brokers that the 40,000 tons of gambier now produced may be largely increased without lowering prices very much, and that all tanners use it. The leather trade of the world is so large, and markets for tanning materials are so numerous, that I believe the cultivation of gambier would be exceedingly remunerative, and I shall be glad to give figures of cost of production if desired.

15, Leadenhall-street.

HENRY WALKER.

THE AMSTERDAM CINCHONA SALES.

(Telegram from our Correspondent.)

At today's auctions, 2,606 packages Java bark were disposed of at an average unit of 6½d cents (equal to

about 1½d per lb. Manufacturing barks in quills, broken quills, and chips, realised from 9 to 57 cents (equal to 1½d to 10d) per lb.; ditto fine root, from 7 to 43 cents (equal to 1½d to 7½d). Druggists' barks in quills, broken quills, and chips, 17 to 139 cents (equal to 3d to 2s 1d); ditto root, 11 to 15 cents (equal to 2d to 3d). The principal buyers were Mr. Gustav Briegleb, the Brunswick Quinine Works, and the Auerbach Quinine Works.—*Chemist and Druggist*, June 13th.

NOTES ON PRODUCE AND FINANCE.

A SPLENDID RESULT.—The shareholders and directors of the Brahmopootra Tea Company, Limited, may congratulate one another upon the excellent result of the year's working and the handsome dividend earned. Mr. Robertson, who presided at the meeting, stated plainly that "the policy of the board was not to stint where good cause for spending was advocated," and so long as this policy, coupled with that of placing complete confidence to the local management, is productive of such a result as a 20 per cent. dividend, there will scarcely be two opinions as to its wisdom. The affairs of the Brahmopootra Company are excellently administered at home and in India, and allowing that this year's results are exceptional, the dividend just declared by this company is not only a source of satisfaction to its shareholders, but should prove encouraging to the tea industry generally, inasmuch as it establishes the fact that, given a good garden and capable management, there are few better and safer investments than Indian tea shares. Shareholders have been slow to recognise this, but it is beginning to dawn on them.—*H. & C. Mail*.

INDIAN AND CEYLON TEA.

38, MINING LANE, June 1891.

MESSRS. THOMPSONS' ANNUAL REVIEW.

If the course of the past season—though full of interest—has been unmarked by incidents which specially distinguish it from the years preceding, the fact may perhaps find no explanation in the assured position as a great industry which Indian [and especially Ceylon.—*Ed. T. A.*] Tea has attained, and the now well-matured experience on which that position is based.

As in the past so now, there have been difficulties to contend with; disappointments to encounter; competition to face; but these notwithstanding, the industry thrives and Indian tea continues to make its way in the markets of the world, justifying the enterprise of those who have made its interests their own.

The sanguine estimates of the crop—which we observe again prevail for the coming season—unfortunately were not realised; and the shortfall of 9 million lb., attributed to untoward weather at the beginning, and the early closing of the season, left the total supply but little larger than that of 1889 to meet the growing wants of the world.

In point of quality the crop was not altogether satisfactory: for while some districts, *e. g.*, Upper Assam and Nsongong, did exceedingly well, others fell below their usual standard until late in the season, when a general improvement took place. The Darjeeling crop with a few exceptions was a disappointing one; but under such conditions as prevailed nothing else could be expected, and its lowered value must not be taken to indicate any falling off in the estimation of good Darjeeling tea, which is far from the fact. Doours and Sylhet have again supplied a kind well suited to the needs of the great retailers, for whom the large breaks, uniform in character, thick and plain in cup, and purchaseable at a moderate price have a special attraction. The produce of the gardens in Travancore, though still limited in quantity, is growing, and promises to develop into a considerable item, now that tea is being planted successfully on the lower levels, and yields a quality which finds favour with consumers.

Throughout the greater part of the year the market was favourable to producers. From the increased consumption which followed the reduction in duty, India derived special benefit, felt not only in heavy deliveries, but also in a more general demand for the better qualities. During the early months rates were maintained without much variation at a level low enough to encourage consumption, yet not so low as to cause apprehension to producers; but before the end of the year prices gave way under the combined influence of the financial crises we suffer, and the inevitable pressure of supply. The

lowest point was reached about the beginning of December, but before the market closed a reaction set in, when it was seen that the crop was likely to weigh out far short of the estimate, and that supplies would be light from China. The movement initiated in December by substantial trade buying, fully warranted by the low prices and steadily increasing rate of consumption, was accelerated in January by speculative transactions, and the eagerness of those who held insufficient stocks to acquire them, with the result that in the space of a few weeks quotations for the lower grades advanced 25 to 30 per cent., and for medium grades 10 to 15 per cent. from the December level. The excellent quality of the latter portion of the crop also encouraged purchasers, and kept up prices without much fluctuation until the end of April, when the market began to feel the influence of the large supplies coming in from Ceylon, selling at gradually receding rates, and by the evidence which figures gave that the higher scale of price was reducing the percentage of Indian tea consumed.

Analysis of the Board of Trade Returns for the United Kingdom shows the fluctuation to have been as follows, viz.:

	Percentage consumed, 1890.	Dec. 1890.	Jan. 1891.	Feb.—April 1891.	May 1891.
	per cent.	per cent.	per cent.	per cent.	per cent.
Indian	52½	57	53½	51	45
Ceylon	18	17½	18½	20	28
China & Java	29½	25½	28	29	27

While ordinary qualities have been subject to these movements, the value of the finer descriptions has been supported more or less steadily throughout, which is due in some measure no doubt to the smaller quantity produced, but more, we think, to a growing appreciation of the merits of good tea; and to the fact, of which evidence accumulates, that formidable as the competition of Ceylon is, it does not affect the finest growths of India. The position indeed, is one that may well encourage those who have proved their gardens capable of producing fine tea, to make that their aim; and the more so at the present time, as the recent rates paid for the lower sorts will probably tempt many to work for heavy crops without special regard to quality. Should this be generally the case, a low range of price for common and medium sorts may eventually result, as it will be difficult to put into consumption another 10 or 12 million lb., wanting the attraction of quality, except by the process of underselling some other kind.

Reviewing the year's trade in its broadest features it appears that, allowing for difference in quality, growers have received more for their produce than in the two preceding seasons. As the average price to the consumer has not been raised in the interval, the inference is either that producers have received part of the remitted duty, or that there has been a shrinkage in the intermediate trade-profit. As regards this, we have authority for saying that a portion of the public elect to pay the price they did before duty was lowered, and to have a better tea; while it is the case that the trade of the country is finding its way into new channels, and is gradually passing from the small retailer into the hands of a class of large distributors, who in order to make and keep their business are compelled to submit to some sacrifice of profit. The extensive scale of their operations enables them to do this; and the producer benefits.

The rapid advance in January, on the mere possibility of a short supply, has also afforded the trade a useful objection on the contingent risk of the modern system of working on short stocks.

The extension of trade with other markets has progressed slowly, owing to the comparatively high prices of the kinds called for, but the increased demand from Australia promises well for the future; and the work which has been done in Canada and the States only waits to bear fruit until the kinds which suit them can be shipped at the rates they will pay. Whilst the United Kingdom absorbs nearly all the Indian tea produced, much expansion in other quarters cannot well be looked for.

CEYLON.—The fortunes of this industry are now closely interwoven with those of India; the same influences shape the course of events, and movements in the one market are quickly reflected in the other. The later months of 1890 were marked by few events calling for comment, production and consumption progressing on parallel lines, while values were maintained at a fairly remunerative level, and as high as could be expected for a crop not plentiful in fine tea, the highest point being reached in October. In the upward movement which took place in January, Ceylon participated, the lower grades rising to a point which carried the average value above the best of October, where they remained until it was seen that consumption was not growing fast enough to take off the large increase in supply. The gradual lowering of rates, however, has placed Ceylon in a better position with respect to other growths, which is of the utmost importance to producers, even though attained at the cost of price—and until more plentiful supplies of Indian are avail-

able, consumption should progress, for there is little prospect at current prices that China tea will be taken in preference by any who are not prejudiced in its favour; especially if the statement that the new crop from the North is "tarry" should prove correct.

The point which most urgently demands attention is that of quality: for the crops of the past year have again fallen short of their early promise, and in a way which justifies the opinion that the cause is within the Planter's control.* We refer, of course, to the absence of tea sufficiently marked by distinctly rich liquor, or finely made leaf, to lift it above the level of average quality, and to the predominance of tea too light in cup and pungent in taste to suit the general body of consumers, unless blended with other kinds. The narrowing range of quotations, to which we drew attention a year ago, has been still more marked of late, and it constitutes a serious drawback to Ceylon that among the large supplies now offered weekly there should be so few breaks worth more than 1s per lb., whereas in a similar quantity of Indian there would be numerous lines selling from 1s 6d upwards. A wide range of quotation is of great help to the buyers in re-selling, and it goes without saying that whatever makes the market a profitable one for them to operate in is for the good of the producer.

We must again refer to the multiplication of breaks. The business is developing so rapidly that buyers cannot value all the samples. Two invoices per week from an estate are frequently seen in print, which is of itself a disadvantage, apart from the extra work entailed. In India the problem has been widely solved by packing the tea directly as it is finished, and storing the chests until large consignments can be despatched. Experience shows that estates which do this, and bulk here, put their teas on the market in high condition; they unquestionably profit by offering larger quantities of their brand at less frequent intervals.

The average price of Ceylon sold in auction during the twelve months has been about 11d per lb.

The following figures for the past season, kindly supplied to us by proprietors, cover nearly 71,000 acres yielding 29,597,000 lb., an average of 413 lb. per acre, realising an average rate price of 11½d per lb.

[We quote all with crops exceeding 500,000 lb.—Ed. T. A.]

District.	Estate.	Average Yielding.	Crop.	Acres	Average Price.
Assam	Assam Co. ...	7,827	2,731,200	349	11-20
	Jokai Co. ...	4,408	2,360,000	521	1 0-75

1889-90...	73,000	29,800,000	408	0 11½
1888-89...	66,000	27,200,000	412	0 10-3-7
1887-88 ...	60,000	22,664,000	377	1 0-1-20
1886-87...	58,300	21,500,000	362	1 0

W. J. & H. THOMPSON, Brokers.

BARK AND DRUG REPORT.

(From the Chemist and Druggist.)

LONDON, June 13th.

ANNATTO.—Dull of sale. For 42 bags West Indian seeds, of good bright colour, 2½d per lb. was paid, while 10 packages very common and almost colourless seed from Ceylon sold at ½d to 1d per lb.

ARECA NUT.—Five bags realised 30s per cwt.

CINCHONA.—Of Crown bark, only a small quantity was offered, and sales are not of any importance; 24 packages very thin, but fair, Bolivian quills sold at 6½d to 7½d; good bright Maracaibo at 5½d; damaged at 2d

* Quality is largely dependent on meteorological conditions, which are certainly not within the control of planters. —ED. T. A.

and 4½d; and 30 packages bold, partly quilly, rather dark Carthagena, imported from Hamburg, and offered without reserve at from 3½d, rising to 4d per lb.

COCA LEAVES.—At today's auctions 1 bale of sound Ceylon leaves, imported via Madras, good strong rather dark leaves of Huanuco character sold at 8½d per lb. Another parcel of 8 bales thin brown leaves is held for 6½d per lb. There has just been a fresh arrival of 15 cases (weighing only about 225 lb. in the aggregate) of coca leaves from Ceylon. The leaves are well cured, but rather dark, of decided Huanuco character, and well packed in tea lead.

ESSENTIAL OIL.—Citronella oil was held for 11-16th d. per oz. in sale today.

QUININE.—The market has been exceedingly flat this week, and prices are lower. German bulk quinine could probably be bought from second-hand holders for 11d per oz., and 10,000 oz. are said to have changed hands at that figure early this week. Another report, however, gives the price as 11½d per oz.

PLANTING IN THE CENTRAL PROVINCE.

[CIRCULAR NOTES BY "WANDERER,"]

THE NEW TEA COMPANY—NO USE EXTENDING TEA—BETTER TEA—THE RAILWAY—THE TEA CROP—COFFEE—CACAO—TOBACCO.

Upcountry man seem to have settled to work, now that the levee gasteries in Kandy are all over.

A little "bolt from the blue" has fallen on employes of the C. T. P. Co., in the shape of "an absence on leave" circular from their jove, who sits on his Olympus in the Hill sanatorium. The Managers of that Company are so well dealt by in the matter of Home leave, that they must expect a little strictness, where absence from the estates on short leave is granted.

Higher rates of exchange, and low prices for tea are exercising the planting mind. The Labour question however is a more pressing one, and the general feeling is clear on the point, that the cases tried in Court so far have been most unfortunate ones, and give the outside public anything but a true insight as to the general relationship of master and coolie.

Many planters are of opinion that there is no use extending the tea area till we have a sufficiency of coolies to do justice to what we have already planted. They maintain that the yield of made tea and its quality depend most on a sufficiency of labour to "catch the flush on the hop." A planter of great experience told me the other day that he could get 500 lb per acre against the ordinary 350 lb, if he could be certain of his labour when he required it. Of course there is the other side of the question how to employ such a labour force when the flushing is scanty?

The New Tea Company deserves the support of all the Planting community. I presume it will run the Tea Kiosk, and supply the orders that will be handed to the manager of that institution.

The tea flushing is now moderated, and the tea turned out of the factories is consequently of better quality. I notice one of your correspondents advising his brother planters to prune in such a way, as to have light flushes in April, May and June. We all wish to get less tea in these months, but Dame Nature is a stubborn old lady. What we all aim at is to prune, so as to have no large portion of our estates coming into full flush at one time.

It is high time that the Government took steps to get their railway engine drivers, stokers and guards, in a less grumbling mood than they exhibit at present. The newly imported guards will no doubt tell their brethren in Ceylon, that Unionism can work wonders in the old country. Measures of reform should be anticipated by employers (Government or private) and not forced on them. A Pension Fund should be at once started, funds being contributed by the Government and (as the Government and the employers share) and ½d by the men themselves.—This will at once make the service a favourite one.

I don't think the outturn of tea will be so large in the last half of 1891, as in the first half.

Coffee will be a very feeble crop this season.

Cacao blossom is kept back by the long-continued wet weather, but we have all July before us.

Tobacco planting has I fear all ended "in smoke."

HAPUTALE WEST DISTRICT; AS IT WAS AND AS IT IS.

The following account of the plantations in this out-of-the-way district was written for us some time ago; but the manuscript got mislaid and so has never been used. The account is, however, of historical if not present interest; but in giving it to our readers, we have secured from a well-informed quarter, a supplementary Report which brings our information up to date. Here is the original paper:—

HAPUTALE WEST.

(Written in 1889)

BANNONG ESTATE.—A small place planted up almost entirely with reputed ledgeriana; since, all available bark harvested, and the place is now abandoned.

CALLANDER ESTATE in the Kalupahana Valley has a field of 40 acres of very fine coffee, which I believe gave 600 bushels parchment last year, and under favorable circumstances it ought to do better this year; it has a considerable amount of cinchona scattered throughout the coffee which has yielded, in shavings alone, large quantities of bark. Under a systematic shaving, from 8,000 to 10,000 lb. of bark, all renewed, ought to be procured. About 40 acres planted up in tea last N.-E. monsoon is coming forward very rapidly.

Mr. MAYOW'S BLOCK was originally planted up in cinchona, and this after the lapse of a year or two (3 years I think) was uprooted and the bark harvested. A very small nursery was laid down with tea seed and allowed to take its chance, and the plants in it thrive so well, that Mr. Mayow has, I believe, since planted up the whole 50 acres with tea.

DENEGAMA ESTATE properly speaking is not in the Haputale district at all, nor does it in any respect resemble the Haputale climate, or share the Haputale rainfall,—it is decidedly in the Balangoda district. I went over it some three months ago with Mr. Smart the superintendent. It has over a hundred acres of coffee which still bears, and I understand that last year's crop was over 3,000 bushels. It also has a considerable area planted up with tea rising two years old and for growth it will compare with any I have seen up here. I don't know what yield of bark it gave last year, but I should imagine that of renewed shavings they could get for the coming year say 15,000 lb. Part of the store has been converted into a tea factory, and plucking will be commenced shortly if they have not already started.

KEENAGAHALLIA ESTATE.—The same remarks apply here as in the case Denegama; the estate is actually within 3 miles of Balangoda town and distant about 18 miles from Haldummulla. It possesses 30 acres of tea in full bearing, besides a number of other products, coffee, cardamoms, cinchona succirubra, annatto, and orotons. The expected coffee crop is 1,000 bushels; and I am, I think, within the mark in putting tea down at 10,000 lb. Mr. Bastard informed me that the annatto and orotons had yielded him very handsome crops, and from the latter more especially which has given him handsome profits. From succirubra he ought, with judicious shaving, to get 5,000 lb. easily as although he has got no large area under cinchona what he has is chiefly 6 or 7 years old and has been only once shaved.

ETTRICK ESTATE has still got fair bearing coffee, but is being rapidly put into tea. They have been plucking leaf for the last nine months, and it is purchased and manufactured for Hiralouvar. The yield is increasing, and judging from the area which will come into bearing this year, 5,000 lb. ought to be easily obtained. I cannot speak as to the coffee or cinchona.

GALTAGANUA is now entirely abandoned, and so is also.

GRUCKERTYA in the Kalupahana Valley.

HIRALOUVAR.—I can give you pretty accurate information as to probable yield of all products here. Coffee, I estimate at say 1,200 bushels. Tea 10,300 lb. from 40 acres; cinchona—renewed shavings succirubra, officialis, and hybrid, from 15,000 to 20,000 lb. and cardamoms from 5 acres 500 lb. Tea promises well here and the growth is decidedly good. There are now 150 acres fully planted up with this product.

LENTRAN in the Kalupahana Valley has been almost entirely planted up with tea, although Mr. White still reaps enough from coffee and cinchona to enable him to plant tea without diving deeper into his purse. It last year gave 400 bushels coffee and about 10,000 lb. of shavings from cinchona, and it will do better still this year as there are some magnificent specimens of succirubra on the estate. The tea will not be bearing for another year yet as it was only last year planted, with the exception of a few thousands put out the previous year by way of experiment.

LEYBURN is another of the Kalupahana places, and now entirely abandoned. It was partly planted with tea, and in spite of the chena which now covers the whole estate, the tea bushes may be seen growing luxuriantly and holding its own against all the surroundings of chena, weeds, &c.

MEERIATENNE, LAST ESTATE IN THE KALUPAHANA VALLEY NEAR HALDUMMULLA.—Planted in coffee and cinchona, but the former is of very little account, and never will recoup the money expended on it. The cinchona is, however, remarkably fine, and nothing in Haputale that I have seen can compare with it. If the value of the product is not going to go out entirely, this will be one of the most valuable cinchona properties in the island. The estate contained at the lowest estimate a hundred thousand of all ages up to six years and the greater percentage is over 1 year old. The trees have never been shaved, and little or no lopping has been done, the proprietor, Mr. Anderson, having an idea that by allowing them to grow as naturally as possible the growth is very much accelerated, and that he will eventually reap much larger profits. Were he to shave the whole cinchona, he could, I think, easily obtain 50,000 lb. bark from one round. There is no tea on the estate.

NAORAK AND NIADOVA, KALUPAHANA VALLEY.—Mr. Orchard has 10 acres of tea here which he still cultivates as regards weeding. It is now rising three years old, and is being allowed to grow up with a view, I think, to becoming seed-bearing trees. If Mr. Orchard cared he might by plucking it regularly, after pruning down, get 3,000 lb. or 300 lb. per acre.

NONPAREIL AND UGALDUA I have never been over, and I cannot speak as to their capabilities. The former has, however, long retained a good name as a coffee-bearing estate.

WEST HAPUTALE is now fully planted with tea, and to those who cast disparaging remarks on the Kalupahana Valley let them visit this estate and believe what they see. The tea is now close on 2 years old, and a finer sheet of tea for its age is not to be found in the island. It is the best criterion that can be brought forward in proof of the Valley being best suited for the cultivation of this product, and we will yet, I think see this much despised corner the scene of busy life. This estate will, ere many years are over, fully repay the enterprize displayed by the proprietor, Mr. Mills, who is in every way worthy of it, for having stuck to his belief in the face of the surrounding proprietors, one and all, abandoning their properties.

WELATENNE is not yet planted up in tea, but the proprietors, I believe, meditate doing so this year. It still contains some very fine cinchona from which a lot of bark has been obtained, and it will still yield as much if a judicious course of shaving be adopted.

All the other blocks in West Haputale are either not opened up or have been opened and ultimately abandoned. There is no doubt about the entire success of tea in the Kalupahana Valley, wherever it has been tried; and I think it is equally certain that, if the article keeps up in price, we will, ere many years are past, see many hundreds of acres fully opened up in this product.

The Report just received says:—

HAPUTALE WEST IN 1891.

The detailed Report on the estate in this district written some three years ago was I think a very correct description and I would not attempt to give you such a careful Report on the present state

of each place, seeing I do not possess the information. In a general way I note any changes taking place when passing along the road, and nothing very striking has been done in Kalupahana to call for a fresh description since the last was written. I see a new factory on Oallender, and another on West Haputale. The open land has been gradually put into tea as the proprietors gained confidence, while they lost faith in coffee and clochona. The tea when planted seems to take a year or so longer to give a return than down in Dimbula, but when once it takes a grip of the soil, it holds its own against all enemies, of wind, or weather, and rather likes bad usage. The bushes after 4 years' growth are stronger than common, and look as if they will yield good results. Of the 3,000 acres sold in 1880, five blocks were entirely abandoned several years ago, after much outlay in opening, roading and building for cinchona estates. The whole is now grown up in jungle, and nothing to be seen except the roofs of deserted hungalows, or hoes. An expenditure of a few rupees an acre would clear the small jungle, and the land is there ready roaded for tea if the proprietors cared to begin again, but no one is in any hurry to return. The original loss of capital has much to do with checking progress, and it points to the formation of a company in which the owners of unopened land would take shares. Several blocks were never felled, and cannot be called abandoned. The best tea land is still unplanted, or at least the easiest lay of the land. The cinchona on some of the estates would have paid well had the average price for bark not fallen below a shilling a lb., but the cultivation will not pay of itself at current rates.

After so many disappointments the proprietors want a stimulus in some shape; and I think Government might make a few miles of a cart road from a station in Ohiya to join the Kalupahana bridle road at about the 6th milepost where I understand it can be made on an easy gradient. The land would gladly be given free if Government will do the rest without asking anything from the planters. The natives as well as Europeans want to use the railway; and a road of some kind must be made there, as well as in all directions where a station is situated. It will be said there is not enough produce to require a cart road yet until more land is brought into cultivation. This is more through the misfortune than the fault of the proprietors, who paid to Government R180,000 eleven years ago, and who hope yet to make something out of their properties. There is land there capable of producing yearly one million pounds of high class tea, if the railway can be made easy of access. It passes within half a mile of the valley, but unless there is a good cart road made to the nearest station on the line, it will be of no benefit to the Kalupahana estates and the produce will find its way to Colombo by Ratnapura at a cheaper rate than carting it back to the Haputale pass.

[We certainly think Government should make the short connecting road referred to—a truly productive work to them.—Ed. T. A.]

JAPAN AND CALIFORNIA.

[We are privileged to copy from a letter of Mrs. Barnett, the wife of the "Whitechapel Vicar" as follows.—Ed. T. A.]

Japan interested us greatly. It is not so picturesque as we expected. Indeed it is not Eastern at all in the sense in which India and China are Eastern. It is a unique fossil startled into life by the vision of the Holy Grail of Western ideas and ideals which it is now pursuing with feverish and passionate enthusiasm. Then the acceptance of Christianity is very beautiful, and I have seen few more impressive sights than the 700 ugly keen upturned faces of the Tokio undergraduates as they listened to the Vicar telling them of the poor and how they could help them. "This matter is not yet arrived with us"—one said—"but it will be with our nation soon and then it is well that we should have understood how to meet it." We had a very interesting time, and

instead of taking a travelling servant interpreter, we invited one of the University students to be our guest and interpreter. In this way we learnt much of the educated thought of young Japan.

Here, in California, there is much to make one sad. At every turn and corner one is cheated. Large firms lending themselves to lies and sharp practices that could be expected only from street hawkers at home. From the carman who cheats you in your change to this country's "Cook" who dodges you, expecting your ignorance of American geography, they all swindle you, and if you complain to what one would hope to be better class people, they say "Wa-e-l I guess it sharpens yer wits to have to look after yourself. You won't catch our young folk napping in this country,"—and you don't; but you do find them without trust in each other, and I think the great verse might be with truth transposed, so as to read "He who cannot trust his brother whom he has seen, how can he trust God whom he has not seen." But the country is wonderful. Miles and miles and miles of land—lovely, fertile, wooded, watered—ready to yield abundantly at man's merest touch.

SOUTHWARD HO!—IN NEW SOUTH WALES.

THE STRIKE—BIG FIRES—FRUIT-GROWING AT PARRAMATTA.

Kollyville, N. S. W., 12th June 1891.

Since my last letter we have had some stirring times in Sydney and in other seaport towns in consequence of the great maritime strike, which extended to the coal miners, sheep shearers, trolly and van drivers etc., etc. This foolish strike continued for 77 days and cost over 100,000 men in loss of wages and some three million pounds sterling, the shipowners and other employers of labor losing another two millions, making a total loss in money alone of 70½ millions of rupees! During these 79 days the public were subjected to much inconvenience and annoyance, the local trade being almost paralyzed. Most of the local shipowners were obliged to lay up their vessels and the few that did run were officered by spare captains (the only class not out on strike) and manned by seasick landmen. It is a matter of history now that the men were bouted all along the line, the fact being that there was no reason whatever for the movement. Some question as to whether or not mates and other officers should join the Trades Union. The men called out were satisfied with their wages, their hours and their employers. They blindly obeyed their leaders, a thing they are not likely to do again in a hurry. During the progress of this strike Sydney was like a city in a state of civil war. Large parties of mounted troopers (regulars and special) continually patrolled the streets, and over 3,000 gentlemen acted as special constables. In consequence of these precautions non-Union men were enabled to attend to their work and peace was preserved.

Then again we have had a great fire, when banks, club-houses and many places of business were destroyed at a loss of some millions sterling. The buildings were too high for the firemen to do much in the way of extinguishing the flames. The shafts of the various lifts used in such monster buildings became so many vast chimneys to draw up the flames, and no power could overcome such fire under such conditions. A law is to be brought in limiting the height of city buildings to seven or eight stories instead of 10, 11 and 12 stories which is now the rule. Later in the year there was another fire. I happened to be in Sydney at the time, and it was the grandest sight I have ever witnessed. A store containing 35 thousand cases of kerosene oil (just landed) took fire and for some three or four hours blazed away furiously. The flames fed by 280,000 gallons of kerosene reached a height of fully 200 feet, and as layer after layer of cases was reached by the fire the flames would shoot up afresh accompanied by loud explosions as the tins of burning oil were shot up into the air. The waters of that part of the harbour were at times one sheet of

fire, and a valuable wharf and a huge stock of timber were also destroyed. The Fire Brigade under Mr. Superintendent Bear worked splendidly. At times so hot were the flames that while one party of men played on the fire another party had to turn their noses on them to keep their clothes from taking fire. This fire was witnessed by some thousands of persons who covered all the heights surrounding the harbour, and altogether the spectacle was grand in the extreme. During the Easter military encampment at Sydney there was a sad catastrophe. A field day was being held, and at one stage of the operations a cutter with a crew of two officers and twelve men belonging to the Submarine Miners Corps left the wharf with two submarine torpedoes which they were to lay and fire (by means of a Siemens dynamo which they carried in the boat) for the edification of the Governor and others assembled to witness the sight. A mine or torpedo of 100 lb. gun-cotton was laid and the boat drawn off so as to fire it, when through some unaccountable blunder the wire belonging to the other torpedo of 150 lb. still hanging at the stern of the boat was placed in the dynamo. They consequently fired the mine still alongside the boat and blew themselves to atoms. The two officers and two men were thus destroyed. The remaining ten men escaped with comparatively trifling injuries, although it is feared that one of them has been rendered permanently deaf by the force of the explosion.

After a residence of twelve months at Milton surrounded by dairy farmers we have come to spend the remainder of my furlough amongst the orange groves and orchards of Parramatta. Fruit growing although not so profitable as dairy farming is still a great industry and is increasing. The chief drawback seems to lie in the difficulty to secure remunerative prices for the fruit. The orchardists of California make large fortunes out of their fruit, but then they have a population of 62 millions of fruit eaters to supply, whereas our Australian population is only about 3½ millions all told. Efforts are being made to send the surplus fruit, oranges in particular to Europe; but hitherto this business has been attended with great risk on account of the length of the voyage and other difficulties. A friend of mine, Mr. Acres, has recently sent 2,000 cases of oranges to London with very unsatisfactory results. As all of the fruit arrived more or less damaged from two causes—the skins of the oranges were not dry enough when packed and the cool chambers of the ship were too damp. Still under proper conditions Mr. Acres feels sure that it is possible to deliver vast quantities of oranges in London and elsewhere in Europe in sound condition at the very time of the year (August, September and October) when there is least fruit there from other parts of the world to compete with ours. In this neighbourhood the orchards vary in size from 10 to 400 acres, and in these are grown oranges, lemons, apples, pears, peaches, apricots, plums, nectarines, loquats, quinces and passion-fruit. The orange season is from June to about November. Lemons bear all the year round; apricots etc., called summer fruit, come in from November to May. The trees are planted 100 to the acre, and come into partial bearing in about four years and into full bearing probably in ten years, at which time each tree ought to yield a return of fruit to the value of four shillings per tree, or £20 per acre: an orchard of 20 acres will thus yield a gross income of £400 per annum. The cost of working such a place would be about £150, leaving £250 nett to the owner. Dear labour is the great drawback in this country where "Oao man one vote" reigned at, and where the majority being of the working class are doing their very best to keep out cheap labour so as to keep the rate of wages to as high a point as possible. False policy, as, with cheap labour, most of these very people who now work so hard could become employers of labour, occupy more land, make more money and enjoy life as we do in the Tropics. A properly managed orchard must be kept well worked and constantly ploughed and much like a well-mauaged coffee estate—be kept free from weeds. The trees must be well

washed with mixtures containing soft soap or sulphur or other chemical to destroy the various insects and fungoid pests. Bone dust and chemical manures are necessary to supply the lack of lime or phosphate or other wants. Certain trees requiring certain chemicals, e.g., oranges and lemons require phosphate of lime, sulphate of lime and sulphate of ammonia; peaches require in addition to these sulphate of potash &c. Unimproved orchard land costs in this district £30 per acre, and it is difficult to secure a good well-planted orchard at even £100 per acre. There is a good deal of hard work necessary on an orchard; but to one capable of working a piece on scientific lines the work is most interesting as well as profitable. Thousands of acres of splendid orchards have gone out of cultivation in consequence of the ignorance and the slothfulness of the owners. "Knowledge is power" here as well as elsewhere. The climate here is colder than that of Milton: we have already had several nights of hard frost. In Milton we had no frost until July. I must now close. In my next I shall have something to say on the question of "Ceylon Tea in Australia."

HENRY R. PIGOTT.

ECHOES OF SCIENCE.

The Government of the United States have appropriated 9,000 dol. to assist some experiments in the production of rain, which are about to be undertaken by Colonel Dyerfurth, of Washington, during this month in the State of Western Kansas. The principle of the experiments is the well-known effect of concussion in producing rain. It has often been remarked that artillery fire in battle has brought down showers of rain; and Colonel Dyerfurth proposes to send up balloons filled with oxygen and hydrogen gas into the atmosphere, and explode them by means of an electric spark sent along a wire attached to the balloons. These elevated concussions will also be assisted by dynamite explosions on the ground. Rain is a great desideratum in the Western Prairie States, and hence the Government support.

A new machine for taking the contour of a country in a short time is in course of construction. It is a bicycle which is simply wheeled on the ground, and as it rises over a hill or descends into a hollow, traces the curve of the surface on a sheet of paper by means of an adjusted pencil. The theory of the machine is too mathematical to enter into; but engineers in trying climates will be glad to avail themselves of an instrument so convenient.

Mr. E. Deville, the Surveyor General of Canada, has introduced a speedy method of surveying in the Rocky Mountain region of the Dominion. It is to photograph the country by a specially designed camera, which is carefully levelled and adjusted. Ortho-chromatic gelatine plates were found to give the best results. Mr. Deville considers the photographs as accurate as a plan which has been laid down by means of a very good protractor. The method is likely to be useful in military operations.—*Globe*.

CONSTITUENTS OF COCONUT MILK, IN UNRIPE AND RIPE NUTS.

Our readers will observe, by the following extract, that the weight of the liquid in unripe coconuts ranges from 230 to 383 grams, while in ripe fruits the weight of the milk was reduced to between 109 and 151. The explanation, of course, is the solidifying into kernel in ripe coconuts of a very large proportion of the substances which were liquid in the young fruit. The proportion of water in the clear milk of young coconuts ranged from 91 per cent to 96, which in the turbid milk of ripe coconuts was reduced to 91. The saccharine matter in the milk of young coconuts is in the form of glucose, varying from 3.45 per cent to 4.58. In the milk of the ripe nut,

glucoso disappears in favour of cane sugar, as nearly as possible equal in quantity. The varying figures for protoids and fat are curious. Had the kernels been analysed, those of ripe nuts would, of course, have shown a large proportion of fat:—

Analysis of Milk of Ripe and Unripe Coconuts.—By F. L. Van Slyke (*American Chemical Journal*). The milk of the unripe coconuts was transparent like water, containing in suspension a little cloudy white substance, which was readily removed by filtration. In the ripe nut the milk was quite turbid in appearance and did not filter clear. The specific gravity was determined by a pycnometer, water by drying at 60° C. and proteids by Gunning's modification of Kjeldahl's method. Hammerbacher's analysis probably refers to ripe coconuts.

Milk of ripe Coconuts. Hammerbacher's analysis.

A NATIVE ACCOUNT OF THE KEKUNA TREE.

We print, *literatim*, a contribution sent to us as a specimen of what the author could do for a free copy of the *Observer*. One sentence must be corrected: the kekuna does not grow "in any district." It is essentially a lowcountry tree which we do not recollect seeing at an altitude of over 3,000 feet.

ABOUT KAKOONA TREES. (By an Upcountry Resident.)

I think some of the tea planters are glad to hear a small article about these trees, although many people have seen them, I do not think they understand the name and what for they are. The Kokoona tree is a very fast growing tree in any district and do not require weeding or anything. These trees are very useful thing to upcountry villagers, many of the poor villagers who have no money to spend for Kerosine oil, they generally using these oil in their houses to light only. In this month many of these poor villagers very busy in collecting these seeds; from 3 to 3½ years the tree will grow up very straight as "toona," and began to give crop 2 times a year. The heavy crop is from this month, (March). When the seeds are ripe, all falling down, the childrens are collecting them once a day generally in every morning. After they collect the seed they have to clean them from the shells and put in the sun to dry them well, when they soon it properly dried, again they have to break it by stones or hammer and to make oil. There are two ways taking oil from kokoona: one way is pressing by a wooden thing, made like a thing press; they have made these things 5 or 6 to a large village, and some baskets made by Kitool. The other way is to take oil by a big chattie from 2 measures of kokoona will give 3 to 3½ bottles oil. This oil can sell 12 to 15 cents for a bottle, after the oil is taken out, the dust is like a ponnac, this is a very good manure for them, I think this ponnac is very good for manuring tea, &c.

BARK AND DRUG REPORT.

(From the *Chemist and Druggist*.)

London, June 20th.

CINCIONA.—A rather moderate supply of bark was offered at auction on Tuesday, the total supply consisting of:—

	Packages	do	do
Ceylon cinchona	600	533	were sold
East Indian cinchona	1,116	1,031	do
Java cinchona	18	18	do
South American cinchona	321	82	do
Total	2,055	1,666	do

The excess in the supply of Indian over Ceylon grown bark, which has been noticeable at our bark auctions for some months, is still maintained, the East India cinchona on this occasion comprised one or two parcels of unusual alkaloidal richness. These were the produce of the well-known "Wentworth" plantation in British India and were shipped from Calicut. One of the parcels in question consisted of 1,180 lb. of natural Lodge's shavings (said to contain an equivalent of 10 per cent s. q.), which after vigorous bidding, commencing at 7d per lb. was disposed of at 1½d per lb.; another (which was reported to analyse 8.85 per cent s. q.), sold at 10d per lb. The proportion of yellow barks (Calisaya and Ledger) at the auctions was unusually large, whereas the grey varieties were offered exceedingly sparingly. The tone was a fairly good one throughout the sales, and over 91 per cent of the Eastern barks sold, with pretty steady competition, at unaltered prices, the unit ranging from 1½d to 1½d per lb.

The following are the approximate quantities purchased by the principal buyers:—

	Lbs.
Agents for the Mannheim and Amsterdam works	135,073
Agents for the Brunswick work	64,400
Agents for the Frankfurt o/M. and Stuttgart works	65,553
Agents for the Amerbach works	39,942
Agents for the American and Italian works	34,080
Messrs. Howards & sons	29,903
Mr. Thomas Whiffen	1,990
Sundry druggists	41,874

Total amount of bark sold	412,415
Bought in or withdrawn	69,824

Total amount of bark offered ... 482,299

It should be well understood that the mere weight of bark purchased affords no guide whatever to the quinine yield represented by it, firms who buy a small quantity of bark by weight frequently take the richest lots and *vice versa*.

An analysis of the sales of manufacturing barks effected at the last Amsterdam auction shows that an equivalent of 1,167 kilos sulphate of quinine sold at 6 cents; 1,406 kilos at 8½ cents; 2,280 kilos at 7 and 317 kilos at 7 cents per unit. Druggists' barks in quills were offered very sparingly. For long Saccubra quills of first quality the figure of 18 s½d per lb. was reached. The richest bark offered was a lot of 27 packages Government-grown Ledger bark in broken stem quills. It analysed 8.27 per cent s. q., and sold at 55 to 57 cents per ½ kilo. The next Amsterdam sales will be held on July 16th.

COCONUT OIL.—Singlish—fine Ceylon, 29s 3d; good Cochin, 34s per cwt.

ORCHILLA.—Ceylon weed is cheaper, a parcel of 33 bales fair flat having sold at 20s per owt. at the auctions.

QUININE.—The market has been very flat this week, and the only sale of which we have heard was one of 7,000 oz. Brunswick in second hands at 10½d per oz., the figure showing a fresh decline in value; that is still the nearest quotation today, but the manufacturers themselves do not seem to care to give any quotation at all near the second-hand price.

NOTES ON PRODUCE AND FINANCE.

THE DUTY ON TEA.—On Wednesday in the House of Commons, on the motion for the third reading of the Customs and Inland Revenue Bill, Mr. Pioton called attention to the large increase in the consumption of tea since the reduction of the duty. According to the statistics given by an eminent firm of teabrokers, the increase in 1890 was between nine and ten million pounds' weight of tea. It might be said that at the time of the reduction of the twopence on the tea duty a large amount of tea had been kept in bond, and was suddenly drawn out. But the statistics, as far as they were available, showed that the increase had continued. This was an indication that the enjoyment

of a healthy beverage was prevented by the duty placed upon it. It was a serious consideration that the effect of a tax of this kind was to keep down below the natural level the consumption of an article of necessity. He thought it was quite plain that the present or any succeeding Chancellor of the Exchequer could not stop at the present point, and that the whole tendency of opinion and of expediency would urge them on until the duty was finally abolished. Apart from the inconvenience involved, there was always an amount of uneasiness occasioned among business men by the existence of the duty and its possible alteration. He hoped the Chancellor of the Exchequer would bear this matter in mind. It was not only the duty that had to be considered, but also the expense of collecting it; and both fell disproportionately on the poor, because the teas recently sold at fabulous prices did not pay and more duty than the cheapest teas. The Chancellor of the Exchequer said the hon. member would not expect him to reply. There was satisfaction in reflecting that the reduction of the duty was one of the causes of the increased consumption of tea. The Bill was then read a third time.

TEA AND ITS DRINKERS.—The British people are doing their best to maintain their pre-eminence as tea drinkers, and this circumstance should console in some degree those who are worried by the vast extent to which rum, whisky, and other intoxicants contribute to the resources of the Chancellor of the Exchequer. For the season ended on the 31st ultimo, the consumption of tea in this country was over 198,000,000 lb. in weight, against a little over 14½ millions a century ago. Of course the population has increased in the interval, but tea consumption has developed a great deal more, and is now much more than three times what it was per head of population in the year 1700.

TOO MUCH PACKET TEA.—That the trade in packet tea has been for some time overdone, is known both at home and abroad. There is, according to the *Grocers' Chronicle*, too much Ceylon packet tea in the market. It says:—"The rapidly increasing popularity of Ceylon tea has, as might be expected, attracted all classes of dealers into handling it. Just as when some years ago, we were inundated with Indian packet tea companies, so almost every week now we find a Ceylon packet tea Company, 'breaking out in a fresh place.' The consequence is that we now have striking titles ending 'Walle,' 'Yalley,' 'Boddie,' and so on, attached to 'judicious blends' of Ceylon and Indian teas, so skilfully blended and named, that they are like the boy stolen by gipsies, who was so altered and disguised that his own mother did not know him. Many a Ceylon tea planter would, we suspect, find it difficult to say what estate the contents of some of those 'Ceylon tea' packets come from, whilst the Cingalose might be forgiven if they failed to recognise or understand their mother tongue 'as she is spok'o' by those responsible for the titles they bear. It was to put a stop to the practice of palming off on the public Ceylon blends containing but a small percentage of the genuine article that the planters presented and obtained convictions against certain tea packers some time ago, and from statements that have reached us it seems that the practice was only 'scotched, not killed,' and we commend the matter to their attention. But another complaint which we have heard about this packet tea trade, and one which specially affects our readers, is the way unprincipled dealers are treating grocers who become agents for them. An enterprising traveller goes into a town and presently secures a respectable grocer to undertake what is promised to be a sole agency for the 'Bottowaddeville' Ceylon tea. Under the belief that this arrangement will be adhered to, the agent pushes the article and works up a trade in it. But no sooner has he done so than he finds the firm for whom he has been acting as agent has appointed others in the same town or district who thus reap the benefit of his efforts. Remonstrance with the packers is unavailing, and at length the agent gives up the matter hopelessly, and resolves that he will never again take up a sole agency."

LAST WEEK'S TEA SALES.—The *Produce Markets' Review* says:—"Owing to the poor assortment of Indian tea the demand continues inactive, and no improvement can be expected until more desirable teas are available. The bulk of the supply brought forward mainly consisted of the lower qualities, which met with a slow enquiry at about late rates. For the few lots of the medium kinds, and particularly broken pekoes, the competition, owing to the unusually small supply offered, was fairly active at higher prices. An increased quantity of New Season's tea, representing several districts, has been placed on the market. The quality is fairly representative of early imports, the infusion generally being thin, and the demand has been only moderate. The quality of the Ceylon teas brought forward during the last two weeks has happily been better than for the previous two months, but this has evidently been due more to the favourable weather than to any extra care in the manufacture of the leaf. When more attention is paid to this many Ceylon planters should easily obtain the rates frequently commanded by Indian teas worth between 1s 9d and 2s 3d."—*H. and C. Mail.*

A FLORIDA PAPER SAYS there are "over thirty-three" varieties of sweet oranges, not to mention the "natural stock," which is a larger and handsomer fruit than the sweet orange, and it is excellent for orangeade and marmalade, but, being very sour, is seldom shipped North. The medium sizes are apt to be the choicest and "probably the very sweetest orange that is marketed is the rusty-coated and rather ill-looking orange, which might be considered inferior by an amateur." Furthermore, "the way to test oranges is to 'bait' them in your hands: pick out the thick skinned, heavy fruit, and you will be right." The light weight fruit is apt to be juiceless—a condition caused either by slight freezing while on the trees, or more probably by the poverty of the soil in which it grows.—*British Quarterly Trade Review.*

THE FRENCH Consul-General of Guatemala directs attention to the great advance which coffee cultivation has made in that country during the last few years. Statistical reports make it appear that in ten years production has more than doubled, and the prices realised by the product have more than quadrupled. It was calculated at the time the Consul-General wrote (11th February) that the harvest of 1890 would reach about 700,000 quintals, representing the sum of \$16,100,000. The extraordinary high price of coffee has led to a transformation of the country; small landowners, who drew from their harvest resources merely sufficient for working purposes, find themselves now with considerable capital, with which they can improve their property. These good results have led to unbridled speculation, and large companies, principally German, have been formed for creating vast "exploitations"; "they have bought for 7 to 8 hundred thousand piasters, or 3 million francs, properties that three years since were estimated to be worth 2 to 3 hundred thousand dollars." The impulse has become general, and every small artisan who was able to save a little has abandoned his first work and turned agriculturist. "This will last as long as the price of coffee rules so high, but a reaction may be produced shortly, and complete ruin will be the consequence of a large number of producers. The harvest of Brazil, which was last year only 1,200,000 bags, is 9 millions this year. The European markets will therefore be largely supplied, and the Guatemala coffee will have to bear a fall in price, of which the reflex will make itself felt on the economic condition of the whole country."—*Indian Agriculturist.*

CEYLON TEAS IN LONDON.

A good many people are expressing the opinion that prices have now touched bottom and that the up-grade has been reached. They are partly induced to believe this because the Ceylon printed Returns have arrived, and these show only 6,200,000 lb. shipped during April, instead of the 7,000,000 lb. which had previously been telegraphed. Others, however, there are who are not so hopeful.

Westhall Estate, Ceylon, had three boxes each containing 5 lb. of Golden Tip, in one case, duty paid, at auction on Thursday. This was one of the fancy lines. The bidding, however, only reached £1 2s 6d, which was declined. It will probably never get any thing like as good a bid again. This Fancy Market is a ticklish one, and no price over good value, such as 5s a lb. should be refused. The mistake made in this case was that of being greedy. The Westhall Estate appears to have been governed by the idea that it would send plenty and get the fancy prices for a decent quantity, fifteen pounds was greedy. Thus as £30 was the last top price paid per lb., the next advertising bidder, to create his sensation must top that bid, and the buyer of the £30 per lb. tea must try and protect his £30 bid or his position at top. So to best record the next fancy line (if they are not already tired of the game), is not likely to sell at less than £35 per lb. Now 5 lb. at £30, the last top price, is only £150 for the advertisement. But 15 lb. at £35 would be £525, altogether too dear a price for the advertisement. Had Westhall Estate been contented with sending over 5 lb., it is not improbable that it would have realized £35 per lb. or £175 for the 5 lb.—as against the bid of £1 2s 6d, or £15 7s 6d for the 15 lb. which they declined, and which they are not likely to see anywhere approached again. Rather a severe blow this. One can understand that at first starting the bidding for a "Fancy Tea," after what has passed of late, several "starting" bids may have been made by parties who had not the slightest intention of buying the tea at such prices, but who jocosely merely lifted it along, to start it on the record-breaking track. Take the advertisement value out of the tea and it sinks back to commercial level, and 7s 6d becomes a fancy price for it, and 5s good value. Being such a simple matter of calculation, a very slight knowledge of the advertising world should have sufficed to caution people from expecting £525 for such an advertisement as this. There is a limit to its value. That limit I should put at £150 to £200, originally, but it is depreciating with each sale in my opinion. Others may differ from this view. Certainly much of the sensation of novelty has become dulled, and the public are beginning to detect the quackery and to laugh at it. Nevertheless, it would pay today, to buy one lb. at £100, for several reasons, as e.g., among others, it would be a cheap advertisement at the price, and it would not be likely to have its record beaten for some time, owing to this class of advertisement being almost played out; so the record would probably be an enduring one, though it should be borne in mind, that as it is the total cost of the purchase, which governs the price paid, there is no reason why, if this class of advertisement is not played out (or is not deemed to be by these buyers, which amounts to the same thing), we should not find these fancy prices should not be paid per ounce, instead of per lb. so soon as the price per lb. becomes so extravagant as to be prohibitory from the advertisers' point of view.

Westhall Estate is now suffering for its lack of grasp of this common-sense view of the situation, and has reduced the value of a good round number of lbs. by having withdrawn the "tip" therefrom. It has not been altogether alone in this failure, as there are Brekers too, who have failed to see the governing factors, from the advertisers' (purchaser's) point of view. This craze may collapse at any moment and waste the effort, otherwise I would venture to suggest a tin box of 10 ounces of superlative tea being sent home, parcels post, duty paid, just to test the matter. Instructions should accompany any; that it is to be sold per ounce (being the first tea ever so sold, would of itself be a great advertisement, and an attraction to buyers, as anything distinctly new always is).

Instructions should also be given that it should be well "puffed," among the competing advertising buyers as some of the recent "Fancy Teas" have been. If the craze is not over by the time such a box arrives, it would probably stand an excellent chance of boasting record. Another tip to Planters is, that, the first few lots of the "Fancy Teas" of late were called Golden Tip. The last, i.e., the one which sold at £30 per lb., was called Silvery Tip. That struck a new line, and of itself was worth a lot to that Tea. There is something in a name, after all. Don't under name your teas; it distinctly depreciates them.—London Cor., *Indian Planters Gazette*.

PADDY CULTIVATION AND POLICY IN THE KANDY DISTRICTS.

An old resident—a European gentleman with most friendly feelings towards the natives, but who has never been blind to their weaknesses, nor to the need of a patriarchal administration—once more addresses us on this subject. His subject is the mischief that will be done, in the Kandy districts especially, if an indiscriminating "abolition" policy is carried out. He says it is quite disgusting to one like himself who has known the people for thirty years (first living in a Kandy village in 1861) to see the ignorant and yet dogmatic, *ex cathedra* way in which certain press writers (the editor of the "Independent" and his correspondents) discourse on a matter of which they can know little or nothing except from hearsay; for their knowledge is based solely on what some of them may have seen in the hilly parts of the Central Province. We extract as follows from the letter before us:—

"I have asserted before, and I now again assert, that in my opinion, an opinion based on 30 years' experience, if the paddy rent be removed it will (in the Kandy districts) simply result in a proportionately smaller area of land being cultivated. It has several times been my lot to see none of the fields cultivated, although water was abundant, and on my asking why, to be told that as their last crop was sufficient for two years, they had no occasion to grow rice during that season.

"What I would suggest is this,—that the Government Agents of the North-Central and North-Western Provinces be asked to send in a return showing:—

"1st.—The extent of soweddumized land left uncultivated during the whole year although there was a sufficiency of water.

"2nd.—The extent of soweddumized land cultivated for only one crop, although there was a sufficiency of water for two crops.

"3rd.—The number of cases where, instead of cultivating soweddumized land lying under their tanks, they had preferred to cultivate the beds of the tanks, specifying those instances in which the hind of the tank had been out and all the water drained off to begin with, so that, should the rains fall, the crops must fail also.

"A Government Agent would probably be slow to admit, but it is nevertheless a fact, that he has no opportunities of seeing the goiyias in their everyday life. He visits a village and is met by tomtom-beaters, flags are flying, and he passes under a triumphal arch to the place where he is to stay. He sees all the men idle, but of course that is because they have made a holiday on account of his visit. But he might go as a tourist, a Surveyor or P. W. D. officer for 300 days in the year, and still find every man idle.

"The goiyia feels perfectly safe from the consequences of his own improvidence; for if he has consumed all his rice, and his growing crop has failed, a relief work is at once started at which such man is paid daily in rice. One result of those relief works speaks for itself, viz., that all local employers of Sinhalese labour lose their coolies, who at once leave them to flock to the relief works."

This is evidently, we fear, a true picture of laziness, improvidence and utter want of shame in being pauperized. One feels that something more than a mild form of coercion is required; and certainly if the only influence now brought to bear to secure cultivation, is prematurely removed, the consequences will lie at the door of a Government that has been fully and fairly warned.

NOTES ON POPULAR SCIENCE.

By DR. J. E. TAYLOR, F. L. S., F. G. S., & C.,
EDITOR OF "SCIENCE GOSSIP."

One of our young agricultural experimenters has just published the results of his application of sulphate of iron to fruit trees and plants generally. Most soils contain iron, but lack sulphur; nevertheless, sulphur is one of the necessary six ingredients in the composition of protoplasm. Grape vines shank and fruit trees canker for lack of it. There can now be no question that sulphate of iron is best of all manures for fruit trees of all kinds. This has been proved to be especially the case when the soil had an excess of lime. Even old apple and pear trees frisked up into rejuvenescent life when their roots were treated to a solution of this mineral. The mixture applied was in the proportion of half a pound of sulphate of iron dissolved in four or five gallons of water, and applied to the roots in a small trench dug for the purpose round the tree.

Dr. M. C. Cooke, the well-known fungologist, evidently does not agree with the suggestion that the attractive colours of fungi are for the purpose of attracting insects, &c., to them, so as to induce them to carry away and distribute the spores. But Dr. Cooke draws the attention of botanists to another class of phenomena, the mimetic resemblances of fungi. He shows that some poisonous species resemble the edible and harmless kinds so closely that only a skillful and careful botanist could distinguish the difference.

Two American chemists, Messrs. W. O. Atwater and O. D. Woods, have published in the *American Chemical Journal* the results of a large number of experiments they have been making on the important subject of the acquisition of atmospheric nitrogen by plants. They experimented with peas, oats, and corn, and they concluded that nitrogen is readily absorbed from the atmosphere by these plants, when treated with "soil-infusion," and that the gain of nitrogen is dependent on the number of root-tubercles which the application of "soil-infusion" induces. It should be remembered, however, that these root-tubercles have been found to be literally nests of bacteria, so that the latter may probably produce the nitrogen by assisting in the nitrification of the soil.

More interesting experiments on this subject still have been conducted by two French chemists, Messrs. Schloesling and Laurent. It has long been suspected that the natural order of plants leguminosae had the power somehow of absorbing atmospheric nitrogen. The leguminosae plants experimented upon were grown in closed vessels, which were so arranged that the gases introduced and withdrawn could be accurately measured and analysed. They found that when the leguminosae plants were watered with an infusion of nodosities from other plants of the same order, there was an absorption of nitrogen much greater than could be put down to errors of experiment. On the other hand, when the leguminosae plants had not been inoculated in this way, and were therefore free from nodosities, no such absorption of nitrogen was observable. It is believed, therefore, these experiments demonstrate that under the influence of microbes leguminosae plants can fix and utilise the gaseous nitrogen of the atmosphere.—*Australasian*.

CEYLON TEA is taking first rank, says the *L. and C. Express*, both for large supplies and moderate prices. The yield for 1891 put at 60,000,000 lb., is somewhat of a staggerer to China traders.

PLANTATION PRODUCTS IN THE CENTRAL PROVINCE:

TEA—COTTON—TOBACCO—CAOAO—ANATTO.

[From the Administration Report for 1890 of
Hon. R. W. Moir.]

The assured and increasing success of the tea enterprise has led to the area cultivated with tea being largely extended during the year. Not only have European proprietors added to their properties, but the facilities afforded at several factories for the disposal of green leaf plucked on native gardens have encouraged natives to plant up abandoned coffee land and chenais. And the improvement observable in the circumstances of the people generally, consequent upon the largely increased circulation of money amongst them in many different ways connected with the tea enterprise, is very marked. The opportunity also for obtaining employment, promptly paid for, which the estates offer, is a great help to the residents in villages where the cultivation of paddy and dry grain has suffered, as it has in many parts of the country suffered, from successive unfavorable seasons.

Experiments made in the cultivation of cotton did not prove successful, and the success appear not to have been generally favourable for tobacco, with which also experiments were tried. Cacao thrives well in Tumpane, Harispattu, and Dumbaru, and numerous small patches are in native hands, but the cultivation of this product does not appear to be appreciably extended by the natives.

[From the Administration Report for 1890 of Mr.
G. S. Saxton, Matala.]

Mr. Hugh Fraser, of Bandarapola estate, has kindly supplied me with the following information:—

Tea is prospering, and is being extended in Matala North, Matala East, Bandarapola, Ukkuwala, Laggala, and the Matala East end of Kotebakka. From 500 to 600 acres were added to the previous area in tea. More expensive machinery, and more of it, is required for tea than for coffee; and it is pleasing, after one gets over the idea of the cost, to see the successful efforts made by engineers to provide tea planters with such suitable and good machinery.

Cotton and annatto have had a check in popular esteem, and have not been much extended. Moisture and insects are the bane of the one, and low prices, consequent on limited demand, of the other. It is believed cotton would do better in a drier climate.

The south-west monsoon was comparatively a failure in the matter of rain; consequently the season was an unfavourable one for tobacco, and the large clearings in Matala are below expectations. This enterprise deserves better results, and these I hope await further efforts.

Cacao continues to improve in favor, and there is the encouraging fact that prices have kept up. Small patches of native plantations of this product are to be seen here and there at long intervals in the villages, but a great deal more might be done in this direction, and further effort impressed on the villagers. Mooron traders are at present prambulating the district, paying 50 cents a pound, equal to R56 a cwt., for cacao, cured in a very primitive fashion. The European cultivation of cacao in various portions of Matala, as for instance Warispola, Mr. Barber's Grevo estate, Yatawatta, Sylvakanda, and many others, is equal to anything to be seen elsewhere in the Island.

Cardamom does well in suitable situations at the higher elevations, but unfortunately there is not much suitable land left unopened, so the extension of this product is scarcely possible. The Mysore variety does better than the Malabar. The lowlands do not seem to be suitable for the successful cultivation of either variety.

An experiment on a limited scale has been made in the district with Coorg coffee, and the result of this clearing will doubtless be watched with interest.

GRAIN CROPS IN CEYLON.

From the abstract of seasons reports for June 1891, published in the *Gazette*, of July 10th we learn that in the Colombo district of the Western Province heavy rain and floods had injured the prospects of crops in low-lying villages to a great extent, but it was not expected that there would be extensive or complete failure of crops in any particular locality. In the Negombo district an unusually large extent had been sown for yala, and crops were thriving; very little damage having been done by floods. The Mahaoya valley dry grain crops were very small, but thriving well. In the Kalutara and Panadura totamunna prospects were good; in Rayigum korala slight damage was caused by floods in paddy bordering Bolgoda lake; in Padun korala low-lying lands generally were damaged by floods. In the Kandy district of the Central Province the prospects of yala harvest so far were very favourable, there having been abundant rain. The yala chena crops in Yatinnuara and Pats Dumbara promised well. In Matale district rains in Matale south were favourable to yala; in Matale north lands under tanks were partly cultivated; in Matale east the maha crop just reaped was damaged by rain; tala and chillies were successful in the north; a good crop was expected from the ohonas generally. In Walapana paddy crops had failed. Coming to the Northern Province, we learn that the prospects of various crops were on the whole good. In the Southern Province the Galle and Matara districts had suffered considerable damage from heavy rain and floods; but the dry grain crops in some parts were very good. In the Hambantota district the yala crop at Tissae was damaged by flies; in other parts prospects were good or fair, except in Tangalla, where the crops were greatly damaged by floods. Indian corn however was ripening a good crop. From the Eastern Province a cheering report comes from Batticaloa district:—

Early and late pinnari crops cut, and turned out excellent. Large sowings in progress for Ettala, including 4,000 acres of pinnari lands cultivated a second time in consequence of large supply of water in the big tanks and the favourable season. Paddy in hand largely in excess of local requirements, and heavy sales being made for export to Jaffna at Rs. 41 per bushel delivered in town and Rs. 25 on threshing-floors in Mannunai pattu. High price due to scarcity in India. Chennai crops all over, but good supply of plantains in markets, and manioc being dried and exported to Jaffna. General condition of district prosperous, and as money is available for reinvestment there is a brisk demand for land for paddy and coconut cultivation to be cleared before next rains. No cattle murrain; foot-and-mouth disease not severe. In Trincomalee district the paddy prospects were good. In the North-Western Province the crop were generally good. From the Anuradhapura district of the North-Central Province the report was:—

Nuwarakalawiya cultivation for yala, prospect good—somewhat restricted by want of seed paddy in some villages. The rain having fallen only at end of May there was no time to arrange for supply of seed paddy to those who wanted it. Most of the village tanks filled except in Keligan and Korosagalla tulaas. Chenas are being reaped. Gingelly crops fair. Tavalu cultivation not yet commenced. Menuri and chillies are being reaped, fair crop. Tamankaduwa tanks are half to one-fourth full. Condition of crops fair. No rain since the heavy rain on May 20th.

In the Province of Uva the prospects were pretty good on the whole, except in Bintenna, where they were unsatisfactory owing to drought and flies. In Wellawaya potatoes were being plauted. Coming to the Province of Sabaragamuwa, we learn that in the Ratnapura district the prospects for the yala harvest in all korales were favourable, though some damage was reported from recent floods. In the Kegalla district also, the yala prospects were good, fair, or middling; and the dry ground crops also promised well on the whole.

SPONGE FISHING OFF FLORIDA.

"The sponge is a strange beast," says an old fisher, who has grown gray in the chase himself. "He ain't a fish, or a hainimal, or a vegetable, an' yet he's all three. Nobody knows what they grows from, or how they does it. But sometimes we'll scrape a place clean and conclude that that's done for, for good. Next year we goes back, an' there's just as many of 'em as hever. An' do you know if you ents up a green sponge under water an' scatters the hits, each hit 'il grow by hitself?" This is authentic. "Nat" Niles, a local celebrity, started a "sponge farm" on Torch Key, thirty miles from Key West, and failed only for want of a cement to hold the sponges to the bottom under water. During the fishing the schooner keeps its catches in wooden pens along the quay-beaches. There the animal matter decomposes, and the ebb and flow of the tide washes it away. When the end of the cruise approaches, the men jump into the water up to their waists at the pens and beat each sponge separately with sticks, rising and squeezing it until the "moat" is all eliminated. Then they load up, run a needle through the sponges, string them together in bunches of ten or a dozen, and joyfully turn homeward.

The largest vessels, of course, can make the biggest hauls, since they can send out the most men in dingies. But the crews all share in the same proportion. A five-ton boat, carrying five hands, including the captain, will perhaps bring back from a three weeks' trip 300 bunches of sponge. These are spread out on the wharf at Key West and sold to the highest bidder, the skippers often agreeing together informally to take nothing below a fixed price. Two hundred good bunches should bring 400 dols. Of this sum the vessel receives a third, and the captain and crew divide the balance equally. The vessel costs about 150 dols. a year for repairs. Where the merchant is the owner, the shares are graded according to the crew's duties. Some years ago Mr. E. J. Arapian, a shrewd Greek, who has practically built up this trade, sank about 12,000 dols. in trying to introduce the Turkish style of diving for sponges. He brought expert divers from the Levant and purchased elaborate apparatus. But when the water is deep enough for divers, it is too deep for small vessels to manoeuvre safely. The State Government since prohibited diving. Appalachicola, in Western Florida, was once a great sponge port, but the industry has fallen off there considerably for lack of attention.

Except in October, the "harricau month" the sponger makes a trip of three weeks every month the year round, spending other week in harbour. "Do I like the life?" says the old skipper before quoted. "No, indeed. It keeps us scatchin' for a livin' an' it's the same thing hever and hever again. We never gets nowhere to see notbink, an' we're away from our families half the time." The cry of "Shark ho!" is the most exciting the sponger usually hears. Among the "keys," where the water has the prismatic tints of emerald and sapphire that you see in Bermuda and the Bahamas, "bonnet-noses" and "shovel-noses" are plentiful. The shovel-nose is a little too fierce a foe for the peaceable spongers. But his conquerer they readily harpoon and "play" until he gets exhausted. Then they bury an axe in his head, hoist him on board, cut out his liver and throw the carcass overboard, where it sinks to the bottom. Many people think the sailors' use of oil for calming troubled waters is a device of modern science. Yet these spongers have been trying out sharks' livers for a generation to get a clearer view of the bottom in breezy weather. The spongers fish twice a week for their own larder. They are better judges of turtle than Chesapeake aldermen. The Florida sponge is superior to that of Bahama, and inferior to that of Turkey. The best native sponge is the sheeps-wool, with a firm but open texture. The grass sponges grow in the shape of hats and pine apples. Sponges are used in nearly all trades, even by carriers for finishing leather, and by potters for glazing their ware. The sponges as they come ashore are bleached with secret preparations (the formula elsewhere is

oxalic acid, potash, and soda), clipped into merchantable shade, and short and haled for shipment. The Malloy steamers for New York always carry a great quantity. There is a large market in England and France. Since Turkey forbade diving in the Archipelago, the best "Turkey" sponges have come from the Barbary coast. There are now more spongers in these waters than ever before, yet the supply was never so great.—*New York Tribune.*

THE CEYLON TEA INDUSTRY.

To the Editor of the "Manchester Guardian."

Sir,—Referring to your article on Ceylon in your issue of today, the following figures will testify to the wonderful development of the Ceylon tea trade:—

	Shipments. lb.	Annual increase.	Percentage of annual increase.
1885	4,411,578	—	—
1886	8,111,137	3,699,559	84
1887	13,600,545	5,689,408	70
1888	24,381,296	10,580,751	75
1889	34,043,935	9,666,789	40
1890	46,901,554	12,858,469	37
1891 (Estim.)	63,000,000	16,098,446	34

The annual percentages of increases in shipments, nearly all of which come to the London market, cannot fail to impress everyone taking any interest whatsoever in the development of British-grown tea generally. The fortunes of Ceylon tea-planters are now closely interwoven with those of their brethren in India. To a very great extent the movements in one market are quickly reflected in the other. The analysis of the Board of Trade returns for the United Kingdom published lately in their annual review by Messrs. William, James, and Henry Thompson shows the fluctuations to have been as follows, viz:—

Percentage Consumption.

	Dec. 1890.	Jan. 1891.	April 1891.	May. 1891.
Indian	52½	57	53½	51
Ceylon.....	18	17½	18½	20
China and Java	29½	25½	28	29
	100	100	100	100

The same authorities are also responsible for the following figures:—

Home Consumption of Tea in the United Kingdom for 12 months ending May 31st 1891.

Indian lb.	China lb.	Ceylon lb.	Total lb.
98,381,000	53,246,000	41,189,000	192,816,000

In addition to which there was re-exported from the United Kingdom for the same period, as per Board of Trade:—

Indian lb.	China lb.	Ceylon lb.	Total lb.
2,327,200	28,952,800	1,426,000	31,806,000

Indian like Ceylon tea nearly all finds its way to the London market, the direct demand for other markets being yet very small and of singularly slow growth. The demands made for these strong teas for export from the United Kingdom is also small as yet, as evidenced by the re-export figures above. While admitting that today Ceylon holds by far the better position with respect to other growths, yet it has been attained only by a sudden lowering of prices, and I think that I cannot be rightly charged with taking a too pessimistic view of the near future when it is admitted by the best authorities that Ceylon exports will again increase this year so very largely. India and Java will also very appreciably increase their shipments to the London market, leaving, in fact, no room for weak China and Japan teas. Indian exports this season to London are estimated at 112,000,000 lb. The London Produce Clearing-house daily quotations are, however, evidence enough that the "good old days" for tea are not considered likely to return in a hurry. Every additional 1d per lb. lost on present low prices means incalculable things

to the British tea planters, who, happily, still continue to be blest with a cheap silver exchange, failing which their prospects would, even now, become somewhat embarrassing. It will be astonishing if, at present prices for British-grown tea, China tea should still be taken in preference by any who are not prejudiced in its favour.—Yours, &c.,

ONE INTERESTED IN CEYLON.

Colwyn Bay, June 15th, 1891.

DIVING.

THE SIEBE-GORMAN DIVING DRESS.

The Siebe-Gorman diving dress as we see today in the tank at the Naval Exhibition is the development of the Siebe costume invented in 1837. The dress is used in all parts of the world, and all submarine operations. The diver must, therefore, be a practical man, able to turn his hand to any trade. Prior construction, wreck-raising, submarine mining, the cleaning and repairing of ships, work in collieries and tunnels—in all such operations the diver is required,

HOW DEEP IN THE DEEP.

Mr. Gorman has drawn up from his large experiences a valuable paper on the art of diving. Here, for instance, is a table which shows the pressure on the square inch at a given depth of water:—

feet.	lb.	feet.	lb.	feet.	lb.
20	8½	90	39	150	65½
30	12½	100	43½	Limit.	
40	17½	110	47½	160	69½
50	21½	120	52½	170	74
60	26½	130	56½	180	78
70	30½	140	60½	190	82½
80	34½			*204	86½

It is obvious that the least flaw in the construction of the dress would be fatal to the diver, and Mr. Gorman is very proud of the fact that no diver has died owing to faulty manufacture. The air pipes are tested to bear a pressure of 100 pounds to the square inch.

SPONGE AND PEARL FISHERIES.

Within these last ten to fifteen years a large commerce has sprung up in the above fisheries, and this can only be attributed to the use of the diving apparatus, which is now daily becoming of greater importance for those purposes: formerly naked divers only were employed, and the result was only the recovery of a limited quantity, as the diver could not remain but a few seconds to collect, and then only in reach of his arms' length; now the divers remain from two to four hours under water, collecting in that time what would have required twenty naked divers. In the sponge fishery in the Mediterranean waters there are employed over three hundred sets of diving apparatus, without reckoning the fisheries at the Bahamas, Bermuda and off the coast of Australia and other parts of the world. The pearl fisheries are rapidly becoming of the greatest importance, not only for the pearls, but also for the shells, the last-named of a certain species fetching from £7 to £8 the cwt. The pearl oyster (classified as the *Avicula margaritifera*) is an oyster slightly larger than the European congoer, and is valuable for the pearl it bears, the shells themselves being of no commercial value; these are found more or less in all parts of the world, but more principally on the coasts of Ceylon, West Australia, Fiji Islands, Malacca, Straits and some parts of the coasts of the West India Islands. The pearl oyster (*Melagrina margaritifera*) is valuable for the shells only, a pair of them weighing about two pounds. These are found in great quantities all over the north coast of Australia, and in the Malacca Straits and coasts of Guinea. Large fisheries are now being conducted with considerable success and profit; and, as the diving apparatus is now being more and more introduced into those fisheries, we may expect them to become a very important industry.

CORAL AND AMBER.

Coral has received as yet very little advancement from the use of the diving apparatus, and the fishermen seem at present bound to their ancient style of

* The greatest depth any diver has descended.

fishery. Whether it is the shortsightedness of the fishermen thinking to keep up the price of coral, or the want of knowledge in the use of the apparatus, we cannot tell; but in the cases where we have supplied diving apparatus the owners have spoken of their great success in obtaining pure specimens in all colours, from the pale pink to the dark red, and in some cases black, and we believe they have not complained either in the commercial point of view. Amber is found in the Baltic, on the coast of Prussia, in tolerable quantities, but as yet the use of the diving apparatus has not formed any important industry. We hope when the attention of practical men has been brought to this fishery, like those already mentioned, the diving apparatus will be the only means of obtaining this important resinous exudation of an extinct genus of coniferous trees from the depths of the seas.*

How to Dive.

Here are a few hints which Mr. Gorman gives to divers:—With inexperienced men it is advisable to have a rope ladder down to the bottom, but an expert diver prefers simply a rope; they must both be weighted at the bottom. Each diver while under water requires a signalman to hold his life-line and air-pipe, both of which should be kept just taut, clear of the gunnel, so that any movement of the diver may be felt. The diver should descend slowly, halting for a few minutes after his head is under water, to satisfy himself that everything is correct, and then continue the descent. If he feels oppressed or experiences any humming noise in his ears, he should rise a yard or two and swallow his saliva several times; he must not continue to descend unless he feels comfortable. If oppression, ringing in the ears, or headache continue he must not persevere, but return slowly to the surface. To dive to great depths, such as 130 or 150 feet, requires men of great practice and able to sustain the consequent enormous pressure. On arriving at the bottom the diver will give one pull on the life-line to notify that he is "all right." In returning from great depths the diver should ascend very slowly, and thus avoid the effects of passing too abruptly from considerable pressure to that of the open air; if he stops now and then, he gets gradually and regularly accustomed to the change. The ascent from the depth of twenty fathoms should occupy about five minutes. "It is more important to move slowly in rising than in descending." The diver takes down with him the ladder line, which he secures to the foot of the ladder or rope by which he has descended; this line should be coiled up in his hand with a loop round his wrist, and as he leaves the ladder he lets the line gradually uncoil, so that if he be at any distance off he can find his way back to the ladder when he wants to return. If working in thick water, while at the bottom he should never let go the ladder line; if by any accident he does so, and cannot find the latter, he must make the signal to be hauled up.—*Fall Mall Budget,*

THE ART OF MANURING COFFEE.

To the Editor Madras Mail.

Sir,—In your issue of the 9th instant you have a long article on this subject by Mr. Pringle, in which he gives the public gratis information that has cost us £5,000 sterling. In the first column, on page 5, he writes:—"The great question is, what is necessary, and how much? To help in the settlement of this question, I submit the aggregate results of some of my experiments, giving the weight of clean coffee yielded." Then follow the results. I think it right to warn your readers that these results are, by Mr. Pringle's own confession, *valueless*. He wrote Messrs. Matheson & Co., in connection therewith, as follows:—"I am very sorry to say that the crop from the experimental plots is very disappointing," and in a letter to myself, added—"The plots were too small, and each one has affected its neighbour. I have compared the results in every way, and it is impossible to say what manure is best." He wrote me again, on 31st March last, "and

though my experiments in regard to manures and leaf disease are incomplete, they have thrown considerable light on the subjects, and the *doubtful* results I have obtained may yet be turned to useful account." In further proof that the results are unreliable, I may mention that the *manured* plots gave an average for 4 years of only cwt. 3.20 per acre, while the *unmanured* gave cwt. 3.05. The excess was, therefore, only cwt. 0.15 per acre, worth, on the trees, say R6, or about a sixth of the cost of the manures and application necessary to produce it. The self-evident conclusion is that manuring, except as a means of keeping the estates alive, is a mistake which carries absurdity on the face of it. His figures with regard to cattle and cattle manure, too, are fallacious and misleading. There is not a bandy and pair of bullocks in Coorg that costs R23-15-4 per annum. If they did, the work they perform would be worth R1-8-0 a day instead of a rupee, and they would work 26 days instead of 24. The profit, therefore, instead of being 8 pie per month plus the manure, would be R16 plus the manure. *Mercers, 12th June.*

C. MEYNELL,

Attorney for Matheson and Co.

II.

Sir,—There is no doubt that planters like the farmers of old in England have a distrust of Agricultural Chemists. Two gentlemen now claim they can cure leaf-disease. It has long been known that any given coffee tree can be cured and kept clear of leaf-disease by the use of sulphur and other agents. As far as a laboratory or garden experiment goes there is no great difficulty in the matter. In fact, without the use of any such agents, if the soil is made rich enough in the ingredients coffee loves (decayed vegetable matter being the chief) a coffee tree will practically defy leaf-disease—that is it will bear heavy and continuous crops and not suffer from them. What any man has to do who wishes to get planters to adopt his cure for leaf-disease is to show them a field of 10 or 20 acres in an estate which he has kept clear of disease for 3 years; which has borne an average crop of at least 5 tons per acre for 3 years, and which shows a marked superiority in appearance and yield to the fields adjoining it. Any man who can do that and patents his process may be sure of every planter adopting his process and paying him a handsome royalty. No system which cannot do this at a moderate cost will ever be carried beyond a garden experiment. Now of the two gentlemen who are offering their cures for our acceptance Mr. Vernode is I believe a planter, and Mr. Pringle has been experimenting for 4 years on Messrs. Matheson and Co.'s estates. Presumably these gentlemen have applied their slop and infallible cures to at least one of the fields under their care. Let them show us those fields and the records of their crops, and if they can show they have made coffee averaging £3 per acre yield an average of £6 per acre by keeping it clear of leaf-disease and borer the planter will be convinced, but *nothing else will convince him.*

I should like to make a few remarks on the article on the art of manuring coffee as it rather illustrates why a planter distrusts an Agricultural Chemist. Mr. Pringle gravely assures us that gram-fed cattle who do not work cannot be made to produce manure under R150 for ten tons of manure. I don't suppose any practical planter ever gives gram to cattle which do not work, but I can assure Mr. Pringle that a cattle manure which has excellent effects on coffee can be made in Wynnad and applied to the coffee at the rate of 15 to 22 tons an acre for R50 per acre—including every charge for tending cattle, cattle sheds, a certain amount of feeding stuffs for the hot weather and medicines, carting and application, and that this is habitually done in the Wynnad over large acreages. I have done as much as 100 acres a year for two or three years, and I know other places where it is done. How Mr. Pringle gets his cost of application up to R3 per acre I don't know. If a cooly applies manure to 100 trees, that is 3 per acre of 1,200 trees, he could fork 70 trees, which would make a total of R704. Another R1 for filling baskets and commission to the

* Amber is washed on to the shores of the Baltic in considerable quantities after storms.—*Ed. T. A.*

maistry would be ample. As 10 tons to an acre is under 20lb. of manure a tree it would not be very hard work and could be easily done for £10 an acre as the total cost of application. Carting can generally be avoided, but if it cannot it would not average over £2 an acre (less at 10 tons to the acre) as carting could not be necessary on all fields. As a matter of fact, planters apply 20 to 30lb to each of 1,742 trees in an acre, or 15 to 22 tons, and this can be done for a cost of from Rs. 13 to £17-8 for application, according to the distance and lay of land etc.

It would be a not desirable state of things if we could dispense with bulky manures, and depend entirely on the advice of the chemist as to the use of small doses of artificial manures. But only the result of which planters so far are certain is that if they can apply sufficient bulky manures, such as cattle manure or decayed vegetable matter, they can be certain of abundant crops. Even those who have been most successful with bone and poona recognise that bulky manure once in three years at least are a necessity, although large accumulations of leaf are received from the shade-trees which are now a *sine qua non* with coffee. Nor do they believe in small doses. £4 of steamed bone dust and £12 of poona every year is a minimum dose, and men would apply more if they could afford it. This may be absolute waste from a chemist's point of view, but it is a fact that such over manuring is the only way to make coffee pay. Nor is this remarkable when we know that over-doses of phosphoric acid improve all crops, even those which have only a small proportion of that element in them. I do not wish to seem captious, I am exceedingly grateful to Mr. Pringle for the information he has given us and would be delighted if he would eradicate borer and leaf-disease. But we have found so often that the teaching of the chemist does not, for some unforeseen reason, produce in the field the effect it theoretically should produce, that we prefer to go on with our old wasteful ways,—certain that the result will be that if we can only apply enough, something or other in the old fashioned manures does tell. If is only rotten wood, 2 or 3 inches of it on 6 inches of mould, will grow such coffee as no artificial manure can. If Mr. Pringle wishes to turn us from our ways let him grow finer fields on regulation doses of artificial manures and we will believe; but that is the only way. SOLVITUR AMBULANDO.

P. S.—How does Mr. Pringle get Incense, clover, etc., to grow under good coffee? I have tried gram (koolty) and find it will not grow under any shade. Of course it might be grown in young coffee.

THE LEAF DISEASE OF COFFEE.

Sir,—In your issue of the 30th there is a misprint, days being written for weeks in the sentences "When the cells are emptied a yellowish spot appears, generally visible about two to three weeks (not days) after the parent spore is planted." In the next column are three errors viz. "the estate was rid of it from end to end," should be "the estate was red with it from end to end." Lower down "The coolies pick up spores" should be "coolies kick up spores," and the word "post" for "host." Now in regard to your Coorg correspondent's letter of the 27th re leguminous trees, *Dalbergia latifolia* (Beetie) is given in Vol. I of the Mysore and Coorg Gazetteer as one; it is certainly the best shade tree in South Coorg judging by the coffee under it. I would suggest that Mr. Cameron of the Lal Bagh, and the Manager of the Madras Agricultural Gardens, Mr. Gleeson, be asked to furnish a list of the leguminous trees that are not surface feeders. Here is an extract which will, I hope, show your readers how the question of the fixation of nitrogen is being worked at:—"It was first in the year 1878 that it was shown by Schloesing and Muntz to be dependent upon the presence of certain minute forms of life, or micro-organisms, or to other words to be a fermentation change." Quoted from F. and G. O. Franklin's "The nitrifying process and its specific ferment." The following is quoted from

"New experiments on the question of the fixation of free nitrogen by Sir J. B. Lawes and Dr. J. H. Gilbert":—"Experiments similar to the well-known ones of Hellriegel, which were commenced in 1883, have been made by the authors at Rothamsted in 1888 and 1889. The results fully confirm Hellriegel's statements, and show large gains of nitrogen over that contained in seed and manure in many cases of leguminous plants grown in prepared sand or soil containing known percentages of nitrogen. The ones showing this luxuriant growth and increase in nitrogen were those in which the root tubercles were well developed and this was brought about by adding a little aqueous extract of the crushed tubercles to the prepared soil, or by watering them with the washings of soil in which similar leguminous crops, provided with root tubercles, had grown. The authors therefore are now prepared to endorse the conclusion drawn from Hellriegel's experiments that although chlorophyllous plants may not directly utilise the free nitrogen of the air, some of them at any rate may acquire nitrogen brought into combination under the influence of lower organisms, the development of which is apparently, in some cases, a coincident of the growth of the higher plant whose nutrition they are to serve." There are over a dozen of the cleverest chemists of Europe and America working steadily experimentally at these questions, and every point is tested by independent investigators, keenly critical, as is shown by the above extract. Leguminous plants may be said to have a parasitic beneficent lower organism developed with them, which possesses the power of rendering nitrogen capable of being fixed by the plant. Thus it is that they afford a cheap means of obtaining nitrogen from the air. As regards shade trees my experience is that, in South Coorg, all surface feeders are bad, and I do not think surface feeding leguminous trees would be exception, but they might. Only experiments can decide the question.

WILLIAM PRINGLE, M. A. C. I.

Bangalore, July 2nd.

COAL IN CEYLON; ELEPHANT LEATHER.

Great interest is felt here in your announcement that coal has at length been discovered in Ceylon. If it can be demonstrated that the material found is absolutely coal, any inferiority of quality which may be reported as to the samples sent home need have no effect in disheartening you as to the ultimate value of the find. All experience has shown that surface coal is of little relative value, and the real quality can never be ascertained until a considerable depth has been reached. Should preliminary reports justify it, we hope to hear that some deep borings have been made in order to obtain samples which may enable an accurate test of quality to be established. We think that geologists who have visited Ceylon hitherto have generally reported adversely as to the likelihood of coal being found in the island but these reports have not shaken the faith of many who have entertained a confident hope that the mineral would be discovered some day or other.

Having read your extract from an American paper referring to the use of elephant leather, I paid a visit this week to Messrs. Toulmin & Gale to learn what they know of the subject. I was assured by them that they had never heard of elephant leather being employed in the manufacture of the articles mentioned in your extract referred to. They said a leather was known in their trade as "elephant leather," but this was only cowhide stamped in imitation of the latter, and they expressed their belief that it was impossible to work up the genuine thing into bags, pocket-books &c. They showed me a piece of elephant hide in their possession and asked me if I did not see the impracticability of so adapting it. However, they obligingly sent for the foreman of their works, with

whom we discussed this matter. He gave his opinion as a practical workman that he could use the leather, but it must be carefully tanned and cut down in thickness as soon as it was lifted out of the tanning pits. Perhaps this is what is done in America, but it is certain that no such process is known here. It must be a very costly one, and to cut down a hide said in your extract to be 1½ inch in thickness to a thinness which would render it available for working up into fancy goods, seems to me to be a useless waste of labour. Even when all was done the leather could scarcely be as supple or as sound as crocodile leather, and it has none of the handsome and peculiar marking which makes the latter such a favourite.—London Cor.

THE INCIDENCE OF OUR ROAD TAXATION

There are few of what we may term our fiscal arrangements that have called forth more criticism from time to time than the relative burden imposed by the collection of money for the upkeep of our roads. At first sight it appears to be an anomaly that the agricultural laborer should be called upon to contribute towards this in the same degree as his more wealthy fellow subjects. But there are few anomalies in the matter of taxation the redress of which would not produce further anomalies which are impossible of being taken into account, or even of being accurately foreseen and provided against.

It is this difficulty no doubt that led to those who originally devised this method of upkeep and extending our roads to ignore altogether any scheme of assessment such as could alone distribute evenly the burden to which we have referred, and to substitute for it a level impost of so many days' labour. Power to commute in money was a necessity of the case. Had not this been allowed, the existing anomaly—if anomaly there really be—would have been intensified; the higher among our social grades would have contributed at rates varying from say £1 to £10 per diem, while the agricultural laborer would have contributed but from 3 pence to 9 pence per day. The power to commute the days of labour for a fixed rate of money payment became therefore absolute, and unless a sliding scale were fixed muleting the planter in so much, the native proprietor at so much, and so on throughout the many varied grades and occupations, it was necessary that the current value of a day's ordinary road labour should be accepted as the standard for everyone whatever his rank or degree in life. Many among those who have brought this question forward from time to time have contented themselves with drawing a sharp line of distinction between natives and Europeans only. They have advanced that the latter should be amerced to a greater extent than the former. They would follow the absurd coach-fare practice still carried out, of so much for Europeans, so much less for Burghers, and so much less for natives. This argument is a ridiculous one, for many natives paying road tax are really better off in this world's gear than are hundreds among our hard-working European population.

There is a strong feeling in most of the more advanced countries of the world that the working classes, as the rule, do not contribute their fair quota to the taxation which provides for them the comforts and security of civilized Government in which all share alike. The difficulty is as to how to reach such classes without imposing inordinate burdens. It is all very well to attempt to fix a boundary line between rich and poor

but it is an acknowledged fact that many of the working classes are better off in their degree than many who rank higher in the social scale. Their burdens are in many respects lighter, and from their circumstances are more easy, relatively, to be borne. In a vast number of cases, too, to increase the burden of the higher classes is to place a tax upon the industry or intelligence which has enabled these to rise in life out of the dead level of the mass of the community. Now in the case of road upkeep everyone is equally benefited. For if proper attention to our roads enables the more wealthy to pass from place to place the more readily in pursuit of mere pleasure, it equally provides facilities whereby an enormous number—in fact the greater portion of the population—can earn a living. Were it attempted, therefore, to impose a tax for road upkeep in proportion to apparent means, the wealthier would be called upon even far more than they do at present to pay for a privilege which is shared in equally by every member of the community.

But it should not be forgotten that in respect of district roads in planting districts—a series of roads by which the Central Province has been scored—half of the original cost, as well as half of the cost of upkeep, is directly imposed on the planters. The native agriculturist in the low country gets a road to his village or neighbourhood, and through it finds a profitable market for his straw and grain, paying no more than his commutation; while the planter for his district road often pays a large sum every year, apart from commutation.

And it must in addition be recollected that the contribution made under the road ordinance is but a proportion only of the outlay required for the efficient maintenance of our highways. Now whence is the balance for this derived? It is drawn from the general revenue, and this we know to be chiefly raised, not from the labour of the classes who elect to work out their apportioned task on the roads rather than commute for it by a money payment, but from the fruits of the industry of the higher classes among the people. No means, we feel assured, could have been better devised to ensure that contribution should be made towards a general good by those who in other respects are relatively free from taxation than this demand for a certain number of days' labour from each and all alike. It enables those who are poor in cash to bear their share of the burden, while it makes it possible for those whose day's labour would be worth a hundred-fold that of the goyia to escape the anomaly that would fall upon them were they compelled to the absolute performance of so many days of labour on the roads. Were this not so, the anomaly complained of as regards present arrangements would be, as we have said, largely increased. All should contribute to a common good, and no method suggests itself whereby this can be more fairly enforced than by the present operation of our Road Ordinance.

COFFEE PLANTING IN EAST-CENTRAL AFRICA.

(By an ex-Ceylon Planter.)

Nyassaland, East-Central Africa,
May 4th, 1891.

Mails to this part of the world are slow and irregular, I got your papers by fits and starts; the last lot just to hand is wishing your readers a prosperous New Year! We hope soon to have more regular mails. The commander of the gunboats on the shore is doing his best with the homo

Government to get a Postal Union Service to the Chinde mouth of the Zambezi, as well as a telegraph station, which I've no doubt we shall get in due course. It is terrible the way the Portuguese humbug the British subjects here, stealing letters containing drafts &c. and only despatching whatever telegrams they think proper, excusing themselves by saying the line is out of order &c.

The British gunboats have just gone down to the Chinde mouth to await the final decision re the free navigation of the rivers. The S. S. "Jamea Stevenson," African Lake Co. Shiré boat, is made the subject of frequent insults to the British flag by the Portuguese; they fire across her bows at night, stop her firewood &c., &c., till the gunboats are constantly running up and down the rivers demanding explanations, &c.

I may tell you I have settled down at planting in this outlandish spot, but would not advise any Ceylon than to come here yet a while, at all events till the country has a settled government. There are two of us, myself and an assistant, armed to the teeth with Martini-Henry rifles and nearly 1,000 rounds of ammunition in the midst of a surrounding population of savages. Although a peaceable and unwarlike people, the life of anyone, black or white, is in the hands of the Chief; so it is as well to be prepared, but it is to be hoped no rupture will take place here, for ours is a peaceful mission and our arms for defense only.

The climate here is like that of Udapussellawa; but there is a lot of fever. After the first few attacks however it only comes in a very mild form, which is easily shaken off by a few doses of quinine.

Until I know you get my letters, as the Portuguese are, and justly too, accused of destroying lots of letters belonging to British subjects, I won't write much.

I may say however that coffee grows here and the climate seems to suit it, but cultivation there is none, the trees are allowed to run to wood, get smothered by weeds, and bear all the crop they can stand without killing them outright, so the planters wonder—and well they may—why the trees won't crop for two years after a bumper.

There is no leaf-disease here, but there is a bean disease; in the inside of the bean black rot sets in, destroying it completely, in most cases leaving only the parchment shell, so that the crop is worthless on some fields. Messrs. Buchanan Brothers attribute the disease to a small scarlet-spotted bug called the ladybird, but I think differently, and blame the clay subsoil for rotting the roots, and crop as the result. Perhaps you would kindly let us know the cause of the disease, and I shall be glad to give you more on the subject.*

Slave-raiding and murder are as common as ever about here. A Chief near this told his people to kill a man of another tribe, and they at once pulled him limb from limb and buried their victim in pieces, for which brutality only a few pieces of calico were paid to the Chief to whom the man belonged.

The Lake Shirwa people and the Matchingeries have been at war for some time and only last week a lot of slaves were sold to an Arab caravan on its way from Kilimane to Nyassa, war prisoners no doubt. It's high time the African Lakes Co. got a charter, or the British Government protected the people and not have such scenes taking place within the sight and hearing of European British subjects who cannot interfere because of their weakness.

P.S.—I send you two mission papers. There has been an unprecedented number of deaths amongst the missionaries lately who have really done good work here about.

The cultivation of the giant sunflower for oil-making purposes is making great strides in Southern Russia.—*E. Mail.*

THE JAVA COFFEE CROP.—According to a telegram from the Governor-General of Netherlands India, the Government's coffee crop in Java for 1891 is estimated at 354,160 piculs.

TEA SALE.—We learn that there is a very good *jat* of tea in the Wynaad, introduced from Assam by Colonel S. Ponsenby Scott, and that one rupee per pound for good *sun* seed is being freely paid. It is also said that several persons are visiting the locality in search of tea land, and it is to be hoped that success has attended them. Time will shew.—*South of India Observer.*

CHINA TEA SEED FOR CALIFORNIA.—The *N. C. Herald* states:—"The Chamber of Commerce at Los Angeles, California, are getting tea seed from Hankow, in order to experiment in tea culture." Even if severe "frozes" were out of the question, the absence of cheap labour would ensure failure.

CONSUMPTION OF NON-ALCOHOLIC BEVERAGES IN THE UNITED STATES.—The accounts for the ten months ended April 30th confirm the view that, while cacao makes good progress in the United States and coffee consumption increases enormously, the use of tea remains about stationary. In the case of cacao, there was an increase from \$1,846,000 in 1889 to \$2,270,000. Coffee rose from \$52,191,000 to \$79,431,000. Tea, which showed a value of \$15,000,000 in 1886 and went down to \$11,345,000 in 1889, recovered only to \$12,865,000. Tea has probably fallen in value, but clearly the Americans are not yet by any means a tea-drinking people.

STEADY PROGRESS IN THE SISAL INDUSTRY OF the Bahama islands is reported by Consul McLain. No small amount of Canadian, English and Scotch capital has been invested therein during the past year. Joseph Chamberlain, for one, has bought substantially the whole of a small island, and one of his sons will manage the enterprise. The matured product is yet small, but by next year will make a very large quantity. The few tons already shipped found a ready market, and samples sold in London were pronounced to be of the best possible quality, and brought 40 per cent higher prices than the Mexican or Yucatan fiber. Little or no American money has gone into the business, notwithstanding the fact that the United States supplies most of the imports of the Bahamas. Possibly Florida will become distinguished for sisal production in course of time. The natural conditions in that state are favorable.—*Bradstreet's.*

EXPERIMENTS in fostering the growth of seeds by electricity are not a novelty, since they were made by Mr. Andrew Cross many years ago, and even in the last century by a Scotch electrician but M. Spechnoff, a Russian agriculturist, has recently drawn attention to the subject. He electrified the seeds of peas, beans, and rye for two minutes by passing a current through them, and then sowed them. The result was that the plants which sprang from the seeds thus treated were much more vigorous than those from unelectrified seeds. Mr. Spechnoff also electrified the soil by burying plates of zinc and copper in it so as to make what is called an "earth-battery." The plates were connected above ground by an iron wire, and the electricity circulated from one plate to the other through the intervening ground. Vegetable seeds planted in this ground gave rise to an astonishing crop. A radish grew over 17in. in length and 5½in. thick; a carrot 10½ in. diameter weighed 4½lb. M. Spechnoff estimates that for root crops the harvest in the electrified earth was four times greater than that in unelectrified ground; and for ordinary plants two or three times greater.—*Globe.*

* Will some expert give us an opinion?—ED. T. A.

Correspondence.

To the Editor.

APICULTURE.

Glasgow, June 25th.

DEAR SIR,—I enclose a cutting from the *British Beekeepers' Record* in answer to a query of mine regarding *Apis dorsata*. I was much obliged for the *Tropical Agriculturist* which you kindly sent me.—Yours truly,

APIS.

[The large bee of Java (*Apis dorsata*) has never been domesticated in Europe. An attempt was made several years ago by a gentleman resident in Barmah (as reported in the *American Bee Journal*) to locate a swarm of these bees in an observatory hive; but after remaining for twelve days in the hive they refused to submit to the ways of civilised bees and absconded. The writer says of them:—

'In the Padang-Karen country, about eighty miles north-east from Toungoo, these bees are in some sense domesticated, as is also the *Apis indica*. In order to secure the services of the *Apis dorsata*, the Padangs dig a trench in a side hill, and drive a stout stake, inclined about 45° towards the down slope of the hill, into the ground, and lean branches of trees against the stake on either side, making a shield from the wind. The *Apis dorsata* returns to these places year after year, and the natives secure beautiful harvests of wax and honey, always leaving some for their yellow workers. May it not be that the *Apis dorsata* builds one comb only because it does not usually find a place to build double combs? The comb is so large that it is lodged in a large limb of a tree to give room for double combs. I am strongly inclined to believe that the *Apis dorsata* can be domesticated, especially the black-coloured species. Yet, to ensure success, doubtless much study must be given to the habits of this bee.' The same gentleman, in a subsequent number of *Gleanings*, again refers to the departure of his swarm as follows:—'The comb of the *Apis dorsata* left with no measures about 2 ft. long by 1½ ft. deep. The honey-comb and brood-comb are quite distinct. The honey-comb is placed always highest up on the limb of the tree on which the nest is built. From this, which is on the right in my comb, the brood-comb extends to the left, new comb being added along the whole edge, from the honey-comb around to the limb again. The honey-comb is three inches thick in its thickest part, but built in a cylindrical form. The natives say they have seen this honey-chattel 6 in. in diameter. The cells are 1½ inches deep, and less as the slope changes. There are three honey-cells to the inch. This comb is beautifully white, and the walls of the cell are almost transparent. Honey is also deposited among the brood, but it seems to be of a different kind from that in the honey-chattel. The brood cells are from ½ to ¾ of an inch deep. The number to the inch varies from 4 to 4½, or 23 cells to 5 square inches. The brood-comb varies a little in thickness, and is about 1½ in., and is a light brown in colour. These bees on the comb form one of the most beautiful sights in nature I ever saw. During their stay they built comb and brought honey and water, but they did not at any time work as if they were happy. Just before leaving there was a great running to and fro, and preening of wings and legs, preparatory to flight. Not more than half a dozen bees remained.'—Ed. T. A.

A TEA WITHERER.

June 25th.

DEAR SIR,—Some short time back I read a letter in your paper suggesting that Mr. Jackson should invent a "witherer." This has already been done, and anyone desirous of seeing same at work can do so on applying to me,

The "Cyclone Witherer" is much used in Assam now, and is patented in Ceylon by the inventor. I understand, it is advertised in the *Indian Planters' Gazette* in India, and it is all the inventor claims for it—a thorough witherer—and I wonder it is not advertised here also. I shall call Mr. Turton's attention to this. He wrote me he would be in Ceylon in February last, but, I fancy, has not had time.

I send you his pamphlet. The one here represented is his first attempt. His improved one is very much better and more effective. I have diagrams of it to show anyone who thinks of getting one.—Yours truly,

WALTER AGAR.

[It is certainly surprising, if the "Cyclone Witherer" is a success in India, that it has not been advertised in Ceylon; but we have seen it strongly condemned by "Peripatetic Planter," Mr. Lepper: Perhaps that may have been an unimproved one.—Ed. T. A.]

IRRIGATION IN SIND.

The Indus Valley Steam Irrigation & Trading Co., Limited, Bombay, June 25th.

DEAR SIR,—May I venture to ask if you would kindly reproduce the article appearing in today's *Bombay Gazette* in respect to Irrigation in Sind, the development of which this company proposes to undertake.—I am dear sir, yours faithfully,

JOHN CRIPER, Managing Director.

SIND IRRIGATION OLD AND NEW.

According to a Government Resolution on irrigation in Sind, which was issued a few days ago, there were during the official year 1880-90 2,109,804 acres of Government lands and 240,015 acres of Jaghir lands under cultivation, or an increase on the figures for 1859 of 223,248 acres and 8,936 acres, respectively, while the revenue, deducting remissions and land share, increased from R44,12,756 to R47,80,323. There is thus an increase in cultivation of nearly eleven per cent, and in total canal revenue of nearly seven and three quarters per cent, over the figures for 1858-59, and of twenty-four per cent, and twenty-one and three-quarters per cent, respectively, over the results for 1857-58. Large as these figures appear, they are very small compared with the total area irrigable in Sind, and much smaller still when contrasted with those of the irrigation works of other provinces. The Ganges Canal, for instance, comprises 437 miles of main canal and 3,569 miles of distributaries, and irrigates 807,574 acres. The Sirhind Canal in the Punjab has 542 miles of main channel and 4,389 miles of distributaries. The Godavari, Krishna, and Cauvery irrigation system in Madras totals 1,246 miles of canal, and waters two million acres. In Sind the system is much simpler, and under existing conditions much less effective. The inundation canals are for the most part mere earthen channels, innocent of masonry dams and scribes, and supplied by the annual rise in May of the Indus and its tributaries. Simple as the system is so far, the method of the ryot in getting the water from these channels to irrigate his lands is even more rudimentary, for he knows no better appliance than the clumsy Persian wheel which has been in use for thousands of years. The cultivator with three pairs of bullocks capable of ploughing an acre and a half per day, has to employ two of these pairs night and day to raise a scanty supply of water barely sufficient to irrigate enough land to keep the other pair of bullocks ploughing six hours a day. Slow and costly as this method is—according to an official return it is estimated that each acre costs on this system R32.8 to irrigate—the Sindhee practically knows none other, and until recently little or no attention has been given to the question of finding a cheap and effective substitute for this dear and effete system.

Recently, however, a Company has been formed under the title of the Indus Valley Steam Irrigation

and Trading Company (Ld.), which, according to the prospectus, proposes to effect this very desirable reform. The capital of the company is £50,000, divided into £5 shares, of which the prospectus informs us £30,000 worth have already been subscribed for in England. The directorate includes the names of Dr. George Yeates Hunter, late Civil Surgeon, Kurrachee; General McLeod Innes, R. E., late Accountant-General to the Government of India; Colonel Ernest Schreiber, of Woking; Captain W. F. Ammesley, of East Sheen; and Mr. John Cripser, Managing Director in India; and a local Board of Directors is in course of formation. Mr. S. W. Anderson, Kurrachee, being the Secretary pro tem. The Company proposes to purchase as a going concern the cotton-ginning factory, and the buildings, stores, plant, machinery, tools, appliances, and all effects connected with it, at Kh-ker, Sind; to erect two other ginning factories of a similar kind at Dera Gazi Khan, and at Mozaffargarh, in the centre of neighbouring cotton districts in the South Punjab, and to develop and work the same under one control; and to take over the business of Mr. J. Cripser of steam irrigation and the supply of water to ryots for the cultivation of cotton and other produce, together with the cultivation leases of about 32,000 acres on the Sarfraz, Inamva, and other Government irrigation canals of the rich lands of the Delta of the Indus, and to irrigate and cultivate them. Ginning operations last roughly from December to April, and in that time, according to the prospectus, each factory working twenty of Messrs. Platt's machines for six days a week, with an output of 100 maunds of marketable cotton per day, can make a net profit of £27,000, at an exchange of 1s. 5d., or say, £1,912, or £5,736 on the intended three establishments for ginning alone. Added to this is the merchant's profit on the purchase of the cotton from the grower of about one rupee per maund—or on the three factories £2,550, making a total profit on the two items of ginning and purchasing cotton of £3,266 nett. At the termination of the cotton season, the engines, which are portable, are removed to the irrigation works, where it is estimated by the promoters very profitable employment will be found for them. The cultivator in Sind during the irrigation season usually takes up for cultivation a small area of about 20 gheribs (10 acres), which is named a Huvla, if worked by a Persian wheel. He requires three pairs of bullocks, or two camels and one pair of bullocks, for this area, and two men and a boy. Two pairs of bullocks are employed day and night at the wheel raising water, and one man is employed in making small channels to convey the water raised over the land. After about a month it is moistened sufficiently to allow of ploughing being commenced. The third pair of bullocks is then set to plough; but water is still required to be continually raised day and night until the close of the season. Consequent on the limited area for which a Persian wheel can provide water, only land immediately adjacent to the canal can, as a rule, be cultivated by lift irrigation, and all beyond 1,000 yards or thereabouts is fallow virgin soil. Lift cultivation is open to such enormous risks owing to the rise and fall of the Indus and consequently of the canals, that the ryot is at one time raising water from possibly a two to three feet lift, and the next week ten to twelve feet, making a difference of two-thirds of the quantity of water raised, the loss on the crop, as remarked by General Pife, in his Note on this subject, being correspondingly great. An average kharif crop in Sind requires about 20 inches, and an ordinary Persian wheel under favourable circumstances as to height of the Indus, &c., it is computed can only provide 12 to 16 inches. On the other hand, when steam irrigation comes into use, it is claimed by the promoters of the company under notice that a 15-inch centrifugal pump raising 4,000 gallons (makers guarantee 5,000 gallons) of water per minute, at lifts of 15 to 20 feet can raise 633,600,000 gallons in 110 days, or one season. This equals 24 inches to 1,000 acres and 22,622 gallons is equal to one inch to one acre. One engine and pump will irrigate 800

acres, while one Persian wheel will only irrigate 10 acres, so that it would require eighty Persian wheels to do the work of one steam-pump. To do the work therefore of which one engine and pump are capable, the ryot, according to the prospectus, at first spends Rs. 200, in wheel, pots, pans, &c., without including the value of the 480 bullocks (about Rs. 10,000 in Sind) required, and their food for the entire year. Steam irrigation will release his bullocks from the main part of their toil, and enable him to plough forty-five acres instead of ten; and for doing this work the ryot is, it is stated, willing to pay seven-twelfths of the crop produced. The company irrigate his food, but it is cultivated entirely by the ryot himself and at his own expense. In connection with this project it is pointed out that the Hyderabad-Omerkore Railway is already commenced, and passes within eight miles of the factory and land proposed to be irrigated, while the Delhi-Kotri Railway has been surveyed, and a company is about to be formed for it. As to ginning, it is also to be noted that the average rate obtained in the Bombay Presidency per maund of 82 lb. is Rs. 1-5 as against Rs. 2-4 in Sind, while the cost of wood fuel in the Bombay Presidency averages Rs. 19 per maund, and in Sind Rs. 13 per maund.

[Mr. Akbar of Negombo, the enterprising coconut planter, who first systematically applied irrigation to palm trees on a big scale in Ceylon, utilizes the steam engine—devoted to the pumps in the dry season,—in the wet season, to run a sawmill.—Ed.]

COFFEE DISEASE IN KANDY.
DEAR SIR,—C. F. Pringle's letter to the *Observer* on the topic against Mr. Pringle's letter to the *Observer* are interesting and his conclusions reasonable, but his proposed remedies appear to be impracticable. I am inclined to believe with General Braybrooke, who, if I mistake not, wrote in your journal years ago, that the disease was to be looked for at the root of the coffee tree, due to some unfavourable condition of the soil; for there can be no doubt that there is a very great diminution and in some instances total absence of the white thread-like rootlets which were in former days so abundant just below the surface all round the foot of healthy coffee trees. In writing to one of your contemporaries a few days ago, your "alphabetical" friend expressed the opinion that he thought the value of salt in agriculture was somewhat exaggerated. It may be so, yet I mention that some time back I procured a cask of compressed seaweed and applied it as a manure to a few coffee trees growing in my compound in Kandy, and it had a very beneficial effect as regards the appearance of the trees; but unfortunately I left Kandy before the time of fruiting, and am unable to say the after results. Examination, however, of the roots of trees a short time after the application of the seaweed showed that numerous little white rootlets were permeating the cakes of seaweed in every direction. An experienced planter told me the other day that bug and leaf-disease are repugnant to each other. That however had bug may be, it disappears immediately *hemiteia* puts in an appearance. There must be some change coming over our seasons, for leaf-disease has come several weeks earlier than usual this year, and bug accordingly took its departure correspondingly early. This change is further indicated by the very unusual phenomenon of albatross being seen in the latitude of Ceylon. I an occurrence I imagine never before heard of.—Yours faithfully,
E. F. TRANCHELL.

TEA PRUNING.

July 8th.

DEAR SIR,—We do not want an "Arboriculturist" to teach us tea-pruning. The science of forcing bushes to give us the maximum amount of flushes

is not the science of the arboriculturist. It is a science peculiar to itself and has been studied on its own merits. As far as I have made it out, the matter stands thus:—The art of pruning for flush depends on the skill of training coolies to recognize red wood and prune accordingly. The man who is fortunate in having rich loamy soil and good developed trees of high jāt on flat ground and sheltered from marauding winds, this man can prune high and make the most of his bushes. But even he will have to cut down now and again to stimulate his bushes. The man who has a great many white-wooded trees of low jāt which are inclined to go to seed; the man who has exposed fields and unfavourable soil, or high elevation and cold temperature,—these men have to prune "as if they were angry with the bush." It is a matter of experience. Commonsense will tell you that bushes which soon shut up, whether on account of soil, jāt, aspect, or elevation, must be kept down and plucked hard from the start. The old idea of pruning for breadth is exploded. You have a fine big bush, and your fields look luxuriant and the ground is well covered; but if you count the number of available shoots in the old method as compared with those in the severe method there is no comparison. We don't want to cultivate trees, and we don't want to kill our bushes. On the one hand we do not want our bushes to run away up, neither do we want to kill them outright. But I think experience shows that the greater distance from the ground the greater likelihood of the sap coagulating. Those "thick leafless sticks" that your tree-cultivator is so angry with are just those from which you will get a red wood. Follow the red wood.

If you have not got a bush with plenty of it cut it down. Follow the red wood according to its individual characteristics and idiosyncracies. If your bushes are white, inclined to blossom, or sulky, or backward in any way—cut away and force a crop of red wood. If you can't get red wood, pull the whole blooming as it is up. But a word to the wise. Don't prune severely in very dry weather, or it is the very devil. The old way of pruning high, then leaving a long pipe of 6 inches on the top of that (to prune into next year, "don'tcher know"), which makes the bushes sulk as long as a pruning, or rather which is in itself a second pruning, then mild plucking on the top of that:—why, before the year is out your bushes are away high up and only the centres are yielding flush. Then the jealous way with which the side branches were guarded from the coolies' ruthless hands. Why, if you leave this they become "bangey," and don't come on. If you pluck them you encourage flushing and draw them up.

Let your maxims be:—

- (1) Follow the red wood;
- (2) No stagnation;
- (3) Commonsense;
- (4) Sweat and shoe-leather.

PRACTICAL MAN.

MICA AND TALC; USEFUL INFORMATION.

SIR,—That talc and mica are commercially interchangeable terms may account for the fact that many people use the term talc when speaking of mica, but how anyone who knows anything of geology could confuse two substances so distinct in composition, appearance and properties, is difficult to explain. There are some who are under the impression that mica only when it occurs as flakes as it does in many igneous rocks, inherits the name of mica; but that when it is found as a distinct

mineral in plates of any size, it should be termed talc. This is as unreasonable as supposing that graphite when it occurs in flakes as a rock constituent must only be called plumbago; but when it is found in any quantity, as a separate mineral it should receive another name. The micas are silicates of alumina with silicates of potash, magnesia and other bases: they crystallize in prismatic forms, and are all remarkable for their very perfect cleavage—splitting into very thin laminae which are flexible and elastic. Talc is a hydrated magnesium silicate and is monoclinic: it is very sectile with a greasy feel, and splits up into thin non-elastic folia. But these definitions and descriptions, which can be found in any book on mineralogy, are quite unnecessary to one who has once seen and felt talc and mica. The soapy feeling to the touch is sufficient to enable anyone to distinguish talc from mica with closed eyes. However excusable it may be for commercial men to confuse these terms, that those who as scientific authorities and heads of scientific institutions should do so, and what is more mislead others, is unpardonable.—Yours D.

"D" renders a useful service in making clear the scientific and practical distinction between Mica and Talc. In the Export Trade accounts of the Government of India we find the heading to ruu:—"Mica (commercially called Talc)"! In the Ceylon Customs accounts, now, the heading "Mica" is omitted and only "Talc" given.—Ed. T. A.]

COTTON CULTIVATION TO BE STARTED AT KARATIVU.—July 19th. Lord A. Osborne and Mr. Butler have been the guests here of Mr. Pennycuik, but left two or three days ago for the Karativu island—a long strip of land lying north of Dutch Bay. It is their intention, I am told, to buy up this island and to plant it with cotton—a capital idea, and one which I hope will be carried out!—Puttalam Cor.

COCONUT CULTIVATION IN THE NORTH-CENTRAL PROVINCE.—By returns received for our Directory, we are glad to see that coconut—like paddy—cultivation under the influence of the new state of things, is fast extending in the North-Central Province. The Government Agent lately instituted a census of palm trees and the result so far as coconuts are concerned is:—

47,613 bearing coconut palms.

34,470 young palms not in bearing.

So that in the past five years, the number of coconut palms previously existing has been increased by 75 per cent. At 50 trees to an acre, the total of 82,083 palms represents 1,026 acres fully planted in the North-Central Province.

RICE CULTIVATION IN THE UNITED STATES.—An elaborate article on this subject, illustrated by engravings, principally from quaint Burmese drawings, appears in the *Louisiana Planter and Sugar Manufacturer*. After a sketch of the history of rice culture and the kinds used and modes of cultivation in Egypt, China, India, Burma, Ceylon, &c., the whole process of growth and "manufacture" in the United States is described at great length. We are reprinting the article in the *Household Register and Tropical Agriculturist*, because hints useful in Ceylon may be obtained from the widely different mode of culture observed in the Western land whether rice seems to have come from Madagascar. In slavery time the enterprise was of great importance, but it was ruined in the Civil War; and the writer of the paper is not hopeful of its revival to any great extent by means of expensive free labour. We have hill rice and irrigated rice in Ceylon: in Carolina the grain is amphibious;—being grown in water, but ripened on dry soil,

COST AND VALUE OF CEYLON COCONUT PROPERTY.

(Communicated.)

Some years ago there appeared in the *Observer* a notice of the sale of two coconut properties, at R38 and R40 per acre, to which the reporter appended the remark, that it was a good price, as they were not in full bearing. It is very possible that the price paid for these properties may be their full value, as they may have been treated on the old native system, or some slight modification of it, that instead of adding yearly to the value tends to depress it below that of the original jungle. At all events, the price paid for the fields in question is less than old ebena in a favourite district commands.

Suppose a would-be coconut planter secures at R20 per acre a tract of land of the average quality of the undulating uplands of the lowcountry, and that he dispenses with the services of goiyas and thus avoids the deteriorating effects of their operations, his first year's work will cost R20, which with the price of the land will make up R40 at the end of the first year. R10 per acre per annum will provide for a conserving but not for a high and forcing cultivation,—such a style of cultivation as will produce the first appreciable crop in the eighth year and its full measure of yield in the fourteenth or fifteenth, by which time the crops will have run up to 2500 nuts per acre at current prices worth R60. At ten years' purchase on the net proceeds, the value of the estate in the fifteenth year will be R50 per acre, having cleared off the whole expenditure with 10 per cent of interest during the previous seven years.

The following table shows the principal and interest of expenditure, the probable crops, and the annual increment of value for each year of the series.

COST AND VALUE OF COCONUT PROPERTY.

Years.	Expenditure and Interest per acre, R.	Proceeds per acre R.	Value R. per acre.	Remarks.
1st.	40	...	50	There are lands that at the same cost will give much better results, and others that will give worse, but this is a fair average result, and one that can nowhere be attained at less cost. At a return of 10 per cent it is better to keep than to sell a coconut estate, in view of the average returns of other agricultural investments; accordingly no one sells coconut property except under financial pressure, or incompatibility of joint ownership, which affords the wanted opportunity to the larger capitalists, who usually make great bargains of any such property that may come into the market. The value of coconut property depends most on the character of the cultivation. Even good soil will not tell under neglect, and indifferent soil may be made to pay well, by liberal and judicious treatment. A dozen years ago, there were hardly any means of comparing different measures of cultivation; now there are plenty of examples of various modes, between the extremes of a close cover of lantana, and garden culture, with heavy manuring,—the one costing R5 or R6 once in three or four years, and the other taking from R20 to R25 per annum. Here are two fields with a strip of paddy field between them, the one four and the other nine years old; one has merely been kept lean, and the other has lately been cleared of

four years' growth of lantana; the plants on the younger field are the bigger and stronger of the two. Here are two adjoining pieces, the one six and the other three years old, the one has been cleared of three years' lantana, and the younger field is four years nearer bearing than the older.

A JAPAN CHEMIST ON THE CONSTITUENTS OF TEA;

AND THE EFFECT OF EXCLUSION OF LIGHT FROM THE GROWING PLANTS.

Paragraphs have appeared in the newspapers regarding some interesting experiments made by a Japanese scientist on tea leaves grown under normal conditions of full exposure to light and on others which were shaded long enough to produce the effect of bleaching on the flush. The result was that the shaded tea was deemed superior, from increased amount of theine and not from diminished proportion of tannin,—the conclusion being thus in support of the dictum of Mr. Hooper, the Madras Chemist, that by no known method of preparation could tannin in tea leaves be increased or diminished, and that the superiority of tea seemed to rest on the larger quantity of tannin contained in it. Professor Y. Kozai's experiments are taken as justifying the inferences, not only that the bleached leaves yielded a finer infusion, but that this finer tea acted more strongly on the human frame than tea normally grown and manufactured. Such are the conclusions indicated in the full and interesting abstract of Professor Kozai's paper which we copy into our *Tropical Agriculturist* from the *Chemist and Druggist*, and which we recommend to the careful attention of orthodox planters who consider shade trees amongst tea as objectionable as if the cultured product were coffee. When tea is well established, experience would seem to show that trees judiciously chosen, primarily for shelter and ultimately for fuel and timber, can be planted over the fields, without danger of injury to the tea accruing from the shade. In the Japanese experiment light was entirely excluded, and with results which, if they can be depended upon, are certainly very curious and suggestive. A partial analysis of bleached and normal leaves showed nearly 1 per cent more theine in the former, with more than 1 per cent excess of total nitrogen and an appreciable increase in "theine nitrogen." Hence, no doubt, the finer aroma and high quality of the tea. But if the analysis of bleached leaves confirmed Mr. Hooper's conclusion respecting tannin, what are we to say—what will Mr. Hooper say—to the figures (if they are correct) for the analyses of leaves prepared as green or unfermented and black or fermented tea? As the result of Professor Kozai's experiments, it is distinctly affirmed that the fermenting process in the manufacture of black tea is destructive of tannin! The figures are so astounding that we cannot help suspecting some error. The percentage of tannin in the original leaves, 12.91, was reduced, so it is affirmed, to 10.61 when the leaves were prepared as green tea, and to 4.89 when manufactured as black tea! What renders this low figure for tannin in black tea the more puzzling is that the proportion of tannin in medium Japan tea is subsequently given at 17.65 per cent. Even recognizing the fact that Japan "oolongs" are more of a green tea than a black, the discrepancy is astonishing. Mr. Hooper will, no doubt, have something to say on a result so directly contrary to that obtained by him. A black tea with only 4.89 of tannin and 3.80 of theine would doubtless be pronounced "delicate in flavour but deplorably deficient in strength."

We cannot help suspecting some serious error in the experiment of the Japanese scientist, for no tea analysis we have ever seen has given a figure for tannin at all approaching 5 per cent in lowness. Indeed 10 per cent is a low proportion. Could the results of the Japanese experiments be at all depended on, it is obvious that due regulation and oven arrest of the fermenting or oxygenizing process would assume a new importance in the manufacture of tea. The low percentage of tannin in the Japanese Professor's experiment may, however, after all, be explained by the technical statement as to "the conversion of large quantities of soluble tannin into insoluble phlobaphene," whatever that may be. It is interesting to learn that the process of refining teas ("final firing" is the term in Ceylon) preparatory to packing in hermetically closed packages, improves the quality of the teas.

RESEARCHES ON THE MANUFACTURE AND ANALYSES OF VARIOUS KINDS OF TEA.

In a recent bulletin issued from the Imperial College at Tokyo, Komaba, Japan, is a very interesting account of some investigations into the values of various kinds of tea by Professor Y. Kozai, of which we give an abstract.

Since good tea can only be prepared from very young leaves, liberally supplied with manure, there should be some difference in the composition of the leaves of young and of old, and perhaps also of manured and unmanured plants. Researches have shown that very material alterations take place in the tea leaf—particularly in its earlier periods of growth—thus:

a. The percentage of water in the leaves continually decreases from the spring up to the autumn.

b. Crude protein and nitrogen-free extract regularly diminish, while crude fibre and etheral extract increase proportionally.

c. Theine diminishes gradually while tannin increases slightly.

d. Substances soluble in hot water gradually diminish up to a certain period, and then increase slowly.

e. As regards the quantity of ash, there is but a slight fluctuation throughout the year, but its components undergo a remarkable alteration: thus, there are a decided diminution of potash and phosphoric acid, and a considerable enhancement of lime, magnesia, and iron; furthermore, the quantities of soda, manugauose, and sulphuric acid increase, while the percentage of silica and chlorine remains nearly constant.

Whether the age of the tea plant may have some influence upon the composition of the leaves is a subject not yet experimented upon, although the opinion that older plants produce hotter leaves prevails among tea-planters. Hence the practice of preferring—or, rather, selecting—the older plants for the preparation of a superior kind of tea: for instance, dew-drops. It is, however, certain that careful pruning and liberal manuring are necessary to obtain a fair crop of the leaves from the older plants.

Still another factor which exerts an influence upon the composition of tea leaves is the peculiar method of screening the plants from light for a week or two just before the time of picking. By this means a peculiar, fine aroma is said to be conferred upon the tea, so that it is very easy, according to Japanese tea-drinkers, to tell beforehand whether or not the tea they drink originated from screened plants. It is, *a priori*, certain that there should be some difference in the composition of the leaves of normally-grown and those of screened plants.

three weeks, after which time the leaves in both parts were picked, when the leaves of the screened plants were found to have been completely bleached. A partial analysis of these two specimens of leaves gave the following figures (per cent. of dry matter).

	Grown in darkness	Grown in light
Theine	4.532	3.784
Total nitrogen ...	7.835	6.945
Theine nitrogen ...	1.311	1.094

A special trial showed that there was no practical difference in the amount of tannin contained in the tea leaves, whether etiolated or green. It seems, therefore, that the chief difference in the composition of these two specimens of leaves lies in the quantities of theine contained. This difference is, however, not due to any new production of the said alkaloid in the darkened plants, but is simply caused by the formation of various organic substances, such as fibre, &c., in the leaves normally grown, and by the destruction of nitrogen-free matters by the continuous respiration in the shaded plants. It is concluded that the tea originating from darkened plants acts more strongly upon the human frame than that from the normal plants.

A large quantity of young tea leaves were next carefully collected from a part of a large tea plantation where the most uniform shooting was observed. The leaves were thoroughly mixed together and treated as follows:—

1. 500 grs. were immediately dried at 85° C.
 2. 1,500 grs. were made into green tea.
 3. 1,500 grs. were manufactured into black tea.
- The following table gives the percentage composition of the dry substance of these three specimens.

	Original Leaves	Green Tea	Black Tea
Crude protein ...	37.33	37.43	38.09
Crude fibre ...	10.44	10.08	10.07
Etheral extract ...	6.49	5.52	5.52
Other nitrogen-free extract...	27.86	31.43	35.59
Ash ...	4.97	4.92	4.93
Theine ...	3.30	3.20	3.30
Tannin ...	12.91	10.64	4.89
Soluble in hot water ...	50.97	53.74	47.23
Total nitrogen ...	6.97	6.97	8.22
Albumin id nitrogen ...	4.11	3.94	4.11
Theine nitrogen ...	0.96	0.93	0.96
Amido nitrogen ...	0.91	1.13	1.16

From this it will be seen that the loss of etheral extract is somewhat remarkable owing to a conversion of a part of the tannin into a form insoluble in ether as a consequence, nitrogen-free extract shows a remarkable increase. The fact that the loss of etheral extract in black tea is less than in the green indicates the formation of organic acids and other components soluble in ether during the fermentation of the leaves. Ash, too, suffers in both cases a slight loss, owing to the mechanical loss of the sap in which it is partly dissolved. The trifling loss of theine may also be attributed to the same source of loss rather than to its sublimation during firing. The destruction chiefly concerns tannin, this happening chiefly during the process of rolling and drying and, in the case of black tea, fermentation is the most energetic agent for the destruction of tannin. It is, indeed, true that it is very prone to alteration, since even during the mere drying of tea leaves in the sun a slight but appreciable quantity of tannin is destroyed. The diminution of extractive matter in black tea is most probably owing to the conversion of large quantities of soluble tannin into insoluble phlobaphene, and also the decomposition of organic matters by the organised ferments during the fermentation of leaves, while in the case of green tea, though a fraction of tannin is decomposed, it will not suffer so far-reaching a change as in that of black tea, and the decomposition-products thus formed may be soluble in water.

From the foregoing it is evident that black tea suffers mere material alterations during preparation than green, since in the former the leaves are subjected to fermentation, while the manufacture of the latter consists entirely of mere mechanical manipulations,

were harvested during the year, but the bulk of this being held with the hope that prices will improve.

CARDAMOMS.—The acreage under cardamoms is given at 295 and the crop at 7,100 lb.

Tobacco has been tried for the first time on a large scale in the Madulsima district, and 200 cwt. have been successfully cured and favourably reported upon. If the experiment should prove financially successful it will no doubt lead to more extensive cultivation.

Cacao at recent prices has proved very profitable, and its cultivation appears to be now better understood, but the area available for it is restricted. The introduction of suitable shade trees has worked wonders in re-enslating old and apparently worn-out trees, and it is to be hoped that whenever suitable soil is available the planting of cacao will now be extended. It is most disappointing to find how little interest the natives take in growing cacao, for in the native gardens as a rule are to be found the soil and surroundings most conducive to its successful cultivation. 725 acres are under cultivation, and the crop for the year amounted to 1,050 cwt.

COCONUT PLANTING IN THE LITTORAL OF THE N.-W. PROVINCE.

It is not often that I trouble the "Old Rag" with 'a few remarks,' as I hope you will give the following a spare corner in an early issue in the interest of those who, unaffected by the glamour of "Tea," will think it desirable to find some role other than that dangerously overdone in which capital might be invested with a prospect of equally valuable if not equally quick returns. Reference is of course made to "Coconuts," and especially to coconuts in the Chilaw district, which are rapidly making it one of the most promising of the younger districts in the Island. Since last writing, the further progress of converting unprofitable jungle into thriving young plantations of coconuts, plantains and manioc—well laid out and neatly hedged with sapan fences—has gone on at a steady rate; and where formerly solitude and all it means reigned supreme, one now sees signs of life and health, prosperity and happiness on every side; due almost entirely to the new start which agriculture has made here and enhanced by the beneficial effects of regular and healthy toil upon the people. Sufficient time has now elapsed since planting was begun, in real earnest, north of the river Deduruoya (not inaptly termed by strangers "the Dreadoya," and which we hope to see spanned by a substantial iron bridge shortly)—to enable us to arrive at reliable conclusions as to the staying properties of our soil, the sandy nature of which has so often proved a stumbling block to otherwise willing settlers. Piles within my knowledge have commenced to blossom in the 5th year, and in the 7th year (quite unaided by manure) are now showing from 12 to 15 per cent of the total number of trees carrying very fair crops. These figures are well within the mark. These trees have not the sickly, early-bearing, early decaying look about them that one might suspect; on the contrary, they have all the appearance that only thoroughly well-established palms from good seed can develop, viz. big boles, healthy bark, dark glossy foliage and well formed nuts distinctly denoting that an abundance of sap is present. To say that this state of things will not continue for very long on our soil without chemical aid is saying much; but to say that with the natural adaptability of the particular form of root-growth of the coconut, the question,—with the perennial manure of the soil at a moderate depth which has enabled the young trees to withstand already one severe drought,—with the salt-laden breezes incessantly sweeping over the land and the example

of mature trees close by in robust health, and with a modicum of manure (without which no real cultivation can be carried on) applied judiciously—the trees will respond to the extent of returning two ropes where only one was expended, is I think as true as it is satisfactory to landholders. Grass is abundant, and consequently cattle-manure can be availed of at a small cost. Labor is now more plentiful than formerly, since most of the Sinhalese villagers have had it practically demonstrated to them, that a good day's work will earn a good day's wage, and have thrown off their so-called "inherent" laziness, and go to work regularly, except during sowing and harvest and their all-too-frequent festivals, which, however, can only be looked upon patiently and as a set-off to the absence of that troublesome system of coast advances in vogue in connection with Tamil immigrants. There is a very large extent of land in this and the adjoining districts suitable for the cultivation of coconuts and which the Government is, I think, desirous of selling. It will all be ultimately sold and the best blocks will of course go first, and my main object in writing now is to put the matter before the Planting public as one solution of the difficulty in regard to easing the tea industry of the burden of congestion which undoubtedly threatens it, but which I for one

will not give up for many years to come. I repeat, it is a fancy to coopt coconut planting, and to maintain fallacies which have taken hold of the minds, concerning delay in obtaining returns, their capital amongst other things, but these fallacies are now exploded; and if Europeans still continue to believe in them, the Ceylonese do not, and they are now making all the running. You will excuse the length of this letter, but will recognise the importance of the finding some outlet for the capital and energies of the Ceylon planter. You may give my name to anyone desirous of making enquiries, to whom I shall be happy to give all information in my power.

G. D. M.

[No one can doubt the importance of the coconut planting enterprise;—the practically permanent character of a coconut plantation, when it is once in full bearing, so that it is a good form of inheritance for one's family, being a full compensation for delayed returns. The establishment of desiccating factories, for the product of which there is, apart from Britain and Europe generally, a very large demand in the United States, adds a new item to the exported products of the palm, while, as population increases, the already great local demand will go on largely increasing. As our correspondent has mentioned plantains, we should like to know if this culture is as exhaustive in the North-Western as in the Eastern Province, where, according to an administration report, a plantain orchard is abandoned at the end of three years. In Western hemisphere plantain orchards when to last many years with no other manure than that of the decaying stalks and leaves,—so we have recently read.—Ed. T. A.]

TEA PREPARING MACHINERY.

It seems to be generally acknowledged that there is no better machine of its kind than Messrs. Brown, Roe & Co.'s Tea Sifter. We hear it well spoken of on every side, and combined with the "Elaston" Cutter, it is likely to grow in planting favour. The makers are kept so busy with orders that no merchant entirely connected with them, informs us, they are booked full with orders to cover at least three months to come! Altogether the firm have sold over 200 Sifters and several have gone to India, indeed as far as Assam from Ceylon.

PACKET TEAS.

For some years past a new development of the tea trade has, to the surprise of the older wholesale and retail dealers, assumed a good deal of prominence. If the advertisement columns of the newspapers, and startling placards at railway stations and on boardings, form a criterion, the public has taken a liking to tea packed in leaden packages, and under fancy names—the latter having generally little connection with any locality where the leaves are grown. That the public should buy, to a certain extent, anything persistently forced upon its attention, is perhaps possible, but tea packed in small leaden packets would have seemed a somewhat hopeless direction, in which to attempt to drive John Bull's tastes. Tea in bulk, in a proper lead-lined chest, undoubtedly keeps better, and has a better aroma and flavour, than it can have it exposed in this climate, and packed into unseasoned lead, ornamented with a label which, the more gorgeous it is, the more it is apt to communicate a taste of paint or glue, to the tea it is meant to adorn. Then these lead packets add as nearly as possible 2½ per lb. to the cost of the tea, and the expense of flaunting them before the eyes of the public must also be enormous.

A new form of advertising has been recently hit on, and a few pounds avirdupois of Tea—whether by concerted action or not does not appear doubtful to the initiated—have been run up at public auction to prices exceeding £10 to £30 sterling per pound weight. Then this fact is similitaneously, and apparently gratuitously, blazoned throughout the Press, of course as a sign of the extraordinary quality of the Tea that the so-and-so companies deal in. As the said companies sell their Tea by retail at 2s to 2s 6d per pound, it ought to be pretty obvious, even to the most casual observer, that they cannot use tea in their packets, costing £5, £10, £20, or as in the case of the last sensational sale, £30, per pound. To purchase five or six pounds at such prices, and worth intrinsically perhaps 3s or 4s per pound, is in reality a cheap form of advertisement so long as people can be found who cannot see through so very transparent an operation. Of course the minute quantity sold at these absurd prices is as far as possible kept quiet.

The public, naturally, are ill-informed in such matters, and the tea trade might look with amused surprise on the apparent demand for packet tea, if it were not that a considerable number of grocers appear to be bitten with the new system. Engaged as most of them are in trying to stop the plague of all sorts of proprietary goods, which yield them so little profit and render them the servants of the manufacturers, it is singular that other grocers should be found, who are actually adopting the system with tea. A grocer cannot manufacture mustard, nor can he grow wine or distil whisky or brandy, or brew beer. But he can, as generations of grocers have done before him, sell good tea out of an hoast tea chest, and make a living out of it for himself, and not for others, while serving the public well. Surely the attitude of the grocers on this question of Packet tea should not be doubtful. They should make it clear to the public that they can sell better and fresher tea of their own, and with a far better guarantee that the source of supply named is adhered to, than if a label, however handsome, is trusted to.

Of course, there can be no reason why every Grocer, if he see fit, should not offer lead packet tea with his own name upon it, if the public desire a costly package, with no advantage attaching to it. But it seems marvellous that any number of retailers, thoroughly understanding their business, should turn their old legitimate remunerative tea business, into a means of sinking their own individuality, and ultimately, of losing their profit for the benefit of others.

One excuse for the new development, is that Ceylon tea will not keep; but if that be so it will surely keep as well, and probably a good deal better, if retained in the original lead-lined chest, than if it is turned out in a London warehouse, perhaps in a smoke fog, passed through mixing machines, and then packed into small packages. It would also be interesting to

know how large a proportion of so-called Ceylon Packet Tea ever saw its nominal place of origin. The trade are well aware that a very great deal of it never was shipped at Galle or Colombo.—*Produce Markets' Review.*

SALAWK GOLDEN TIPS.—We hear that the small parcel of tips from this estate has been sold privately at K20 per lb.

THE TEA MARKET.—A broker writes:—"Did you ever see such an irregular market? The *poorness* of the teas is keeping prices down—and unless you and the rest of the press advise planters to go in more for quality we shall see still lower rates!"

A SERIOUS CHARGE AGAINST CEYLON TEA AND TEA PLANTERS is thus preferred by the London correspondent of the *Indian Planters' Gazette*:—

Ceylon—The quality so far from improving is still on the down grade, and invoices containing any Teas with the old characteristic Ceylon quality are now getting extremely rare, and when they are offered, command very good prices. On Thursday the bulk being poor, prices fell ¼d to ½d per lb. It looks as though quality were being set aside for quantity in Ceylon, and a race begun for record in yield per acre. The more the pity. Is it that, having made the record for price, (as made so much of in advertisements now-a-days) there is an intention to show wonderful yields per acre, that allusions to the prices obtained by Ceylon Teas plus a heavy yield per acre, may make prospectives of future Ceylon Tea Companies, Limited, all the better bait to catch the British investor? Are there such Companies in nubibus? If not, why this abandoning of quality and desire to excel in quantity?

COFFEE PLANTING IN DUMBARA.—The following information which we have collated for our Directory is of interest at this time, to our planting readers generally.—

At Koudesalle in Dumbara in 1887 Mr. Hamlin, the General Superintendent Oriental Bank Estates Co., commenced opening some old coffee land which had been abandoned for about 20 years. 104 acres were planted with coffee plants raised from "Nalkanaad" Coorg seed—the coffee was planted 5½ ft. × 5½ ft. and *Cacao Forastero* 11 × 11. The clearing was planted also 11 × 11 with *Ficus glomerata* for shade, all the ridges were planted with grevilles. The clearing now in its fourth year is most encouraging; the coffee is very vigorous and is bearing a crop which will more than pay the cost of the clearing—the cacao is unusually robust and the shade is most satisfactory, it having been carefully pruned and thinned out. The above company is extending more land on this system which appears a paying one, for even should the coffee not last many years, it would have served the purpose of bringing the cacao to bearing, free of cost to the proprietor.

COCONUT PLANTING AS AN INVESTMENT.—The great drawback to coconut palm cultivation as an investment, in the estimation of Europeans, is the long delay in obtaining a return on the capital invested. "Who is to wait 15 or even 12 years," says the colonist bent on an income within 5 or 6 years, but who, nevertheless is too often destined to remain hard at work, long after the time at which coconuts would have come into bearing. Still 15 years is a long period to look forward to for adequate returns; and therefore the report on the Chiraw district—or rather that of Puttalam as just North of the Deduruoya,—with good big palms beginning to bear well by the 7th year, opens up a new prospect, and offers special encouragement to invest in a culture so steadily, if not handsomely remunerative as coconuts are generally recognized to be. "G. D. M." is known as the European planting pioneer of the Rajakadalawa district, and we believe he does not exaggerate in his description of conditions and prospects, as qualified by enquiries in our footnote.

THE PLANTING INDUSTRY IN WYNAAD.

A brief discussion has recently been held in these columns between our Wynaad correspondent and our contributor of planting notes, "St. Louis," concerning the state of the planting enterprise, and more especially Arabian Coffee, in Wynaad. Wynaad is that tract of upland country which lies between the Nilgiri plateau and the Western Ghats, at the extreme southern end of these before they fall away and form what is commonly known as the Palghat gap. The elevation varies from 2,000 feet at Macintoddy, North Wynaad, to over 4,000 feet at Nellacotta in South-East Wynaad. The rainfall along the ghats runs as high as 200 inches in the year, while in the districts remote from them 70 inches may be stated to be the annual average. Wynaad obtained a notoriety in the London financial markets early last decade by the reckless and prodigal manner in which Gold Mining Companies were floated, and in the majority of cases nothing was ever done to justify their existence. These Companies still exist, and own large tracts of land in South-East Wynaad. After most of their capital had been squandered in the purchase of worthless machinery, in the erection of extravagant buildings and the construction of unnecessary roads, in the remunerations of directors and the upkeep of a large establishment in London, and after the cultivation had been permitted to go to rack and ruin for several years, they suddenly turned their attention to this, and devoted the residue of their capital to irregular and perfumatory operations in the field. The natural consequence has been that the cultivation has hardly paid its way, and where a profit has been made which was not entirely swamped by London charges, it has been so dwarfed by the gigantic original capital as to appear next to *nil*. It is no wonder that the British investor should come to look on Wynaad as a veritable "Dismal Swamp" in which no one except a Mark Tapley could be happy. He has been told that it is the land of Ophir, but discovers that gold is conspicuous by its absence. It is pointed out to him as a second Omani, a land flowing with milk and honey, or, to be exact, rich in coffee and quinine, but so far as his balance at his bankers is concerned, it might be a howling Sahara. These Companies are doing much to retard the planting industry. It would be a fortunate day when an influential Company with a small capital was started to take over these tracts of land and to open out cultivation on a sensible and economical plan. With work carried on systematically and regularly and the cultivation of several products undertaken on a paying scale, there is but little doubt that such a Company would be able, in the course of a few years, to return handsome dividends to its shareholders.

The first fact that particularly impresses itself on the mind of the Planter travelling through Wynaad for the first time is that it is essentially not a one product district. Coffee, both Arabian and Liberian, tea, cinchona and pepper all grow vigorously and crop well, and if we are beside the mark when we say that money was made out of all these products last year, a disastrous bad season; yet if we except Liberian coffee, which has just begun to be planted up, we are well within the truth when we state that during the past quinquennium, coffee, cinchona, tea and pepper have all yielded a handsome profit in one or other district of Wynaad. Wynaad is split into three divisions, known as North, South, and South-East. The first two are in the collectorate of Malabar, the last in that of the Nilgiris. These divisions, with the exception of North Wynaad, are sub-divided into planting districts, the South into Vayitri, Meppadi and Sultan's Battery; the South-East into Nellacotta, Devala and Cherambadi. Vayitri, Devala and Cherambadi are situated on the ghats, but where the ghats at Vayitri face the west, at Devala and Cherambadi they face the south. Meppadi lies close to the Ghats, but is protected by the Vellora Mulla range of hills. Sultan's Battery and Nellacotta are inland; and their rainfall only averages from 60 to 70 inches in the year. The various situations of the districts, with their different rainfall and

elevations, make one district better suited for one product and one for another; so that we find at Vayitri that tea, cinchona and pepper thrive best; at Meppadi, coffee, cinchona and pepper; at Sultan's Battery, coffee and pepper; at Cherambadi, cinchona; at Devala, tea; and at Nellacotta, coffee and cinchona. Sultan's Battery and Nellacotta have the best reputation for coffee planting at the present day. The latter is a comparatively new district which has attracted the attention of successful coffee-growers in other parts of Wynaad and in Coorg, but there are some old estates there which have given splendid results for many seasons in succession. In Devala tea has lately been opened out with the most satisfactory results, and it will in every probability do equally well at Cherambadi, now simply a cinchona producing country; and as these two districts have a large supply of local labour, Coymbure and jungle tribes which live in Wynaad all the year round, there should never be a want of hands for plucking leaf. Meppadi is a district in which every product appears to thrive equally. Vayitri may be said to be the last ghât district in which coffee has lingered. Last year leaf disease went through with terrible virulence, and much land had to be abandoned. Here are some of the finest fields of cinchona, more especially Ledger, that are to be seen in Wynaad. Pepper flourishes and "crops" well, and has been proved to pay in this district. North Wynaad is the healthiest part of the country, and contains the only town of any size, Manintoddi. There is but little cultivation left here, though tea should grow well on the hills all round the town, and there would never be any want of labour. Pepper cultivation should also prove a remunerative enterprise. On the Bramagheries, some twenty miles north of Manintoddi and bordering on Coorg, there are one or two coffee estates which produce a bean that in boldness, weight and colour is not surpassed by any coffee in Southern India.

In every district of Wynaad more land is being opened out this monsoon under one or other product. It is estimated that a thousand acres of coffee *Arabica*, and five hundred acres of Liberian coffee will be planted up.* A large acreage will be opened with tea, and Ledger cinchonas, and lakhs of pepper outtings will be put out. The labour supply is adequate, so there will be no delay in pushing on with the work, and the last accounts to hand speak of perfect planting weather. The planting industry is evidently in a healthy and expansive state. We should like to see more capital brought into the country, and there is no reason why there should not be, if only Wynaad could get rid of that bad name which the gold fever left behind it and for which the desultory cultivation to which we have already alluded, has since been largely responsible. With five such staples as Arabian coffee, Liberian coffee, cinchona, tea and pepper all growing luxuriantly and cropping heavily when seasons are at all favourable; the country should attract the attention of capitalists both large and small. There are very few corners of the world where a young fellow with a love of outdoor life and a little money at his back is more likely to get a handsome return on his capital and at the same time to lead a more healthy and happy life, in a good climate with lots of shooting, both big game and small game, at his door, and plenty of pleasant neighbors. The large capitalist ought also to find a good investment for his money here, provided that he does not put all his eggs into one basket but cultivates all the various products, not experimentally, but on a large remunerative scale, and opens out land in various districts simultaneously. Coffee has recovered wonderfully after last season's bad attack of leaf disease; cinchona if only rich in quinine, still pays in spite of the low unit, and this wave of influenza that has swept over England shows that a little thing is needed to send the price up; tea is in a transition state, but it is generally thought that the increased consumption of Indian and Ceylon kinds will keep pace with increased production; the pepper market is depressed

* Then, surely the leaf fungus has disappeared or is comparatively innocuous?—Ed. T. A.

just at present, but each year new markets will be found in Central Asia and the interior of Africa which will help to keep down stocks; so that taking things altogether, we may safely assert that the prospects of the planting enterprise in Weynaad are today as bright as they have been at any time in the past.—*Madras Times.*

TOBACCO PLANTING IN DELI, SUMATRA.

(From an old Ceylon Planter.)

I intend writing you a brief letter very shortly; in the meantime things are at very low water at present; prices for our tobacco ranging from 100 to 150 per cent* lower than last year.—1892 will show a very great diminution in the planting area, and it will go very hard with a great many assistants and managers after October of this year. Estates are being reduced and closed all round. I myself am doing well; shall be very glad to see any old Ceylon friends who may think of taking a look round here;

THE DUTCH MARKET.

AMSTERDAM, June 29th.

CINCHONA.—The cinchona sale to be held here on July 16, 1891, will consist of 3,548 bales and 406 cases, about 335 tons bark. From Government plantations, 292 bales 71 cases, about 28 tons; from private plantations 3,266 bales 335 cases, about 306 tons. The bark is divided as follows:—*Druggists' bark*: Succihrna quilla, 310 cases; broken quilla and chips, 114 bales 45 cases; root, 89 bales; Calisava Schnkhraft quilla, 8 cases; broken quilla and chips, 9 bales 11 cases. *Manufacturing bark*: Lederiana quilla, 3 cases; broken quilla and chips, 2,351 bales 17 cases; root, 685 bales; officinalis quilla, 15 cases; root, 49 bales; hybrid quilla, 2 cases; broken quilla and chips, 161 bales; root, 90 bales. Total 3,548 bales 406 cases.—*Chemist and Druggist*

THE EXTENDED USE OF QUININE.

The valuable medical properties of quinine as a medicine, the advisability of the drug being more extensively used, and the possibility of a decline in the cultivation of cinchona, the source of quinine, has called forth a protest and a warning from a correspondent in the *Economist* against what the writer declares to be the unreasonably high prices at which it is sold by retailers. According to this correspondent, who seems to be well informed, while quinine is sold to the public in various parts of London at from 6s to 8s per ounce, it can be purchased from the most noted manufacturers by the retailer at 1s 5d per ounce. Singularly enough, though ten or eleven years ago the wholesale price was 12s an ounce, and has become so cheap since 1880, the retailers of the drug have generally declined to follow the wholesale market. And though it is at present sold at some stores at 2s an ounce, realising even then a profit of over 40 per cent, "so far as the great mass of the public is concerned," the retailers have "practically succeeded in maintaining the price at an altogether artificial, and to many a prohibitory level." The mention of quinine is not likely to awaken pleasant memories among those who recently suffered from influenza, but they at least can only be glad to see a universal prescription recognise its value. It was universally prescribed as one of the best prophylactics that could be taken during the epidemic, and the medical fraternity are well aware that an "increased supply of this unique drug cannot fail to be a benefit to the world at large." The high prices at which it is sold to the public, if the correspondent's facts be correct, not only deprive poor

people of a useful remedy, but, the supply being limited, the cultivation of cinchona is not so profitable as it ought to be. At present, according to the best authorities, the normal consumption of quinine is 7,000,000 ounces, and the fall since 1880 in the value of the drug annually consumed in the world is put down at no less than 3,750,000 pounds sterling at wholesale prices. There is a glut in the market, because, it is said, the retailer sells the drug at an enormous profit, the result being that the trade in bark with South America has been practically destroyed, and in Ceylon while the number of cinchona trees was 90,000,000 in 1882, there are only about 19,000,000 trees in the island now. Most of the bark imported into England, however, comes from India. If the correspondent's facts be correct it is evident that the price of quinine might be greatly reduced with advantage to all.—*Manchester Courier.*

THE MICA INDUSTRY OF SOUTH AUSTRALIA.

A £500 ORDER FROM AMERICA.

Mr. W. Crooks, of Port Adelaide, received a letter on Wednesday from Messrs. Henry W. Peabody & Co. of New York, giving some interesting information respecting some samples of mica that had been forwarded to them, and enclosing an order for an experimental shipment to the value of £500. Messrs. Peabody & Co. order 1,000 lb. of mica of sizes varying from 3 x 5 inches up to 7 x 9, and at prices ranging from 8s 4d per lb. to 14s 8d per lb., delivered in New York, the purchasers paying the duty. The value of this 1,000 lb. will, at the prices named, exceed £500. The prices show that America is a decidedly better market than England. Though this is an experimental order Messrs. Peabody & Co. plainly indicate that if the shipment is satisfactory it will lead to further business. In their letter of instruction as to shipment they mention that the first thing to do in preparing mica for the American market is to get patterns made of hard wood and for the exact size. They use a pattern made of black walnut about 1 inch in thickness and cut with regular shears made for the purpose. In cutting mica care should be taken not to cut over cracks and imperfections. The mica as it comes from the mines should be split up into thicknesses 1-16th of an inch, so that the cutter can hold the piece up to the light and see that the pattern is not placed over cracks and imperfections. After the mica is cut it is then taken by the cleaners and each size sorted and weighed up in pound packages according to size, and packed in boxes of 100 lb each. Messrs. Peabody seem to lay stress on the necessity of having mica properly cut and put up in a proper manner. They indicate that the total sale for first-class mica throughout the United States does not exceed \$200,000 per annum. There are mica mines in the country, and importations are likely to be restricted owing to a recent duty of 35 per cent placed upon mica by the McKinley tariff. With regard to the quality of samples sent them by Messrs. Crook & Brooker, Messrs. Peabody & Co. state that much admiration has been expressed as to the quality and size of the larger pieces, but unfortunately a proportionate increase of price is not secured, owing to the large-size sheets having to be cut in smaller pieces before being marketable. Of the smaller pieces of cut mica sent the quality varied, appeared as if had been taken near the surface. If such is the case, and the mine holds out, it is likely to become clearer and better further down. Another element which is criticised is the iron which is mixed to a considerable extent with the mica, which renders it useless for electricians' purposes. They thought, however, that certain veins of the mine would be clear from this element. A quantity of mica is imported from India, and owing to the cheapness of labour India would probably be a strong competitor to contend against. Nearly all the mica shipped from India is forwarded in a cut state, and arrives ready for market. Another criticism regarding the mica from

* Impossible! 100 per cent less would be nothing at all: our correspondent means 50 to 75 per cent.—*Ed. T. A.*

South Australia is that it is far softer than the Indian or American mica. Messrs. Peabody state that several of their friends are quite ready to purchase Australian mica if it can be laid down at the right price and good quality, and their order is for an experimental shipment; they also send samples of mica according to which the order must be filled. If the shipment is satisfactory it will no doubt lead to larger orders. They thought that the 85 per cent. duty and the high cost of labour in Australia, as compared with India, would be two obstacles that would be difficult to surmount in the development of this industry. On the whole the communication from New York is considered to be very favourable, and the prices at which the order is to be filled are very satisfactory. The sample of American mica forwarded does not from appearance seem to be equal to the usual samples of South Australian mica.—*Adelaide Observer*.

RAINFALL: EXPERIMENTS EXTRAORDINARY.

The Agricultural Department at Washington have made an experiment, as our readers are aware, in the production of rainfall. A halloon was sent up into the clouds, where it exploded with great violence. Later in the evening a downpour of rain occurred; but (we thank Kutter's correspondent for the postscript) "whether this was due to the explosion has yet to be determined."

It is not likely that our 'onte Yankoo friends are wrong; and as the experiment "is to be repeated on a large scale," we had better look out. For if a downpour of rain can be produced, why not a blizzard or an October gale? Meanwhile have every season to believe in the genuineness of the following announcements.

NEW YORK.—Tuesday last being a foggy day experiments of a novel kind were attempted in order to clear the surface of the sun. For this purpose the new electro telescopic Hotchkiss gun which has been stationed upon the summit of the statue of Liberty was heavily charged with nitro-glycerine and a hundred packets of Messrs. [Notice to Advertisers.—This space £5 5s.] world-purifying soap, and repeatedly discharged at the luminary in question.

The following Thursday, June 25th, was a fine day. It is understood, however, that this may not prove the success of the experiment; that Messrs. [see notice above] do not guarantee their soap to clean objects outside the terrestrial atmosphere.

CHICAGO, Aug. 1.—The municipal authorities having determined, at any expense, to secure fine weather during the World's Fair, a perfect army of stationary and moveable halloons are to be continuously employed in the removal of any clouds found upon or above the premises of the exhibition. Rain-clouds declining to "move on" are punctured and exhausted by a novel and interesting electro-hydraulic pump. The atmosphere is strictly watched at night by means of the electric search light. The adjoining states have already complained of an excessive and disproportionate amount of rainfall and are petitioning Congress on the matter.

VERY LATEST NEWS.—The Protectionist party in Washington have organized a committee of scientists to consider the proposal mooted by a well-known financier for the manufacture of a European blizzard. It is believed that the experiments have so far been of an encouraging nature, the only drawback arising from the difficulty of direction; the idea being that the atmospheric disturbance should only operate on free trading countries.—*St. James's Budget*.

THE CHINA TEA TRADE.

In considering the China tea trade it is not often that a ray of light is found to relieve the general sombreness of the picture. In his report on the trade of Foochow for 1890 Consul Phillips tells us that "taking all things into consideration the year under review has been more prosperous than the preceding one for the foreign merchant." He has to add, however, that it has gone badly with the native tea brokers, the losses sustained by many of them having been very great. The total quantity of tea shipped from Foochow last season was 452,000 chests, as against 576,000 chests in 1889-90 and 596,000 in 1888-89. The quantity taken for the Australian market as well as that for London shows a large decrease, and the present season will no doubt see a further falling off. The reason that the last season proved comparatively profitable for the foreign merchant was that there was a short supply from India as well as from Hankow, a condition of things which is not likely to be repeated very often. The demand for teas of a common kind led to the shipment of a large quantity of tea many seasons old, and on the arrival of this tea in Melbourne a great quantity of it was at once condemned by the Customs Authorities as unfit for human food. As the Consul remarks, this must prove a heavy blow to the Foochow trade, which cannot at the present moment afford to have the quality of its tea called in question. The incident will doubtless give a further impetus to the growing demand for Indian and Ceylon teas in the Colonies.

It is satisfactory to find that in the Fokkien tea districts some attention has at last been paid to the plant, the shrubs being properly trimmed and well attended to, with favourable results. The authorities are awakening to the fact that if the Foochow teas are to hold their own against those of India and Ceylon more care must be paid to their cultivation and preparation, and they appear, Mr. Phillips says, to be ready to listen to any suggestion that promises to bring about an improvement in the trade. The most valuable suggestion that could be given them, but one which we are afraid they will not be willing to listen to, is that the export duty and *lekin* should be swept away *in toto*. This is the only course that can save what remains of the trade, for it is absolutely impossible for China to hold her own against her equally or more favourably circumstanced competitors while she continues to handicap herself with taxation to the extent of 25 or 30 per cent. To take measures for the improvement of the article is an excellent thing in itself, but what has been the cause of the deterioration in the quality? Mr. Phillips tells us there was a time when the Foochow teas were so well prepared that they retained all their good qualities for a season without considerable deterioration. Under the pressure of the competition from India and Ceylon the producers have adopted the no doubt shortsighted policy of scrapping the quality in order to make up for the taxation from which their rivals were free. Remove this crushing load of taxation and the farmers and others concerned in the industry would have more reason to improve the quality of their tea.

Consul Gardner, in his report on the trade of Hankow for last year, enumerates the advantages India and Ceylon tea growers have over those in China as follows:—1st, greater command of capital; 2nd, facility of obtaining loans at a lower rate of interest; 3rd, freedom from *lekin*, *octroi*, and export duty; 4th, command of a better and cheaper labour market; 5th, command of chemical and agricultural knowledge; 6th, better acquaintance with tastes and requirements of purchasers; 7th, easier modes of transport; 8th, greater nearness to countries that purchase; 9th, enormous public works facilitating irrigation in dry seasons and preventing floods in wet seasons; 10th, large size of tea estates; 11th, better machinery. Against all these advantages of the Indian and Ceylon grower, China, Mr. Gardner says, possesses one advantage, and that is, that the Chinese tea-grower, working for his own hand instead of for wages, brings often greater care and more

industry to the task. Experience takes the place of science, and he is able to produce a finer flavoured tea than has yet been produced in India. A noteworthy tea tree in the tea trade of 1890 has been that some of the Russian and British merchants at Hankow have sent skilled agents to the tea-frsers in the interior to teach them how to select leaves and fire the tea, so as specially to suit the Moscow market. The crops thus produced have sold so well in Russia that Mr. Gardner anticipates that this year this operation will be extended. But it is only a question of time how soon the Russian tea trade will follow the example of the English trade and draw its supplies from India and Ceylon, which are already busily nursing the market. To concentrate attention on the improvement of quality will not save the trade to China, for India and Ceylon are also studying the taste of the consumers and every year the superiority of China in the matter of flavour is diminished. To free the trade from its burden of taxation is the only course China can adopt for her own salvation as a tea-exporting country; thus done, improvement in the quality of the article would naturally follow the demand. At present the position of the Chinese tea producer is much the same as that of a tradesman in embarrassed circumstances who, being hard put to it to make ends meet, cannot afford to improve the quality of his wares.—*Hongkong Daily News.*

COFFEE BORER.

GLYTUS COFFEOPHAGUS (DUNNING).

By WILLIAM PRINGLE, M. S. C. I.,
LATE AGRICULTURAL CHEMIST TO MESSRS. MATHESON & CO.
IN COORG.

(Under special arrangement for publication in the
"Ceylon Observer" and "Tropical Agriculturist.")

This insect is the larva of an elegant beetle generally known as the "fly," from its likeness to a horse-fly or wasp. Scientifically it is one of the Coleoptera, of the genus *Glytus*, and is represented in America by the Hickory tree borer, *C. pictus* (DUNNY) and locust tree borer *C. robustus* (FORSTER). The generic name *Xylotrupes* signifying wood borer has also been applied to this insect; and if people are not satisfied with DUNNING's name, *Glytus coffeophagus*, I would suggest the name *Xylotrupes Coffea Indica*, which simply means Coffee Borer India, and leaves the question of sub-order and genus open. But planters are very little interested in names, and a beetle which has wrought such havoc, killing off estates *in toto*, decimating others, and even in those most free from it causing an appreciable loss, is to them the "coffee borer" in its larva state and the "borer fly" when it has developed into a beetle.

During my four years' residence in Coorg I have been collecting statistics of damage done by "Borer" and experimenting with remedial agents. I have been successful beyond anything I hoped for, not only in unravelling the history of the beetle but also in applying remedies; it is easier to deal with than leaf-disease, *Hemiteles vastatrix*.

It is possible in from three to five years to reduce the losses of the trees on the estates by treating the tree for leaf-disease and borer simultaneously, by from fifty to seventy-five or eighty per cent, calculated on the present losses. More it is useless to expect, as a great many trees die out from over-bearing and other causes.

The following is an approximate statement of the trees ripped out, and entered as "Borer" in South Coorg from estates under European management:—

Year.	Rainfall inches.	Crop out.	Per cent of trees on acreage.
1885	62.31	5	8.3
1886	57.82	3½	6.9
1887	71.00	4½	7.0
1878	50.65	2½	8.8
1889	65.98	2½	8.9
1890	50.68	2	8.5

Neither the average crop nor the rainfall appear to have much to do with borer failures. But when the details are examined a very close connection is found to exist between the weather and both crop and borer.

I cannot in the brief space allowed, fully discuss the meteorological features of the question in this paper, but will just say that when the number of sun-spots were at the maximum the crops were good, as the number decreased so did the crops, and as they are now on the increase, crops will probably prove good till the maximum is again passed. [Our correspondent alone is responsible for this theory. What is certain is the melancholy fact that crops have gone down in 6 years from 5 to 2 owt. per acre.—Ed. T. A.]

For the purposes of this paper we will consider that the averages of the various styles of planting give fifteen hundred trees per acre original planting.

It takes fully three years for supplies amongst old coffee to come into bearing, and I would not be far off the mark if I said fifty per cent fail in South Coorg.

However to carefully understate the case we will suppose all to come on. Then the land out of bearing per acre of cultivated coffee was in

1887	Equal to	22.2 per cent.
1888	"	22.7 "
1889	"	24.7 "
1890	"	25.2 "

All this is paying taxes, absorbing work, and manure, and taxing the best energies of our planters to prevent it increasing.

The insect was the subject of Government inquiry some years ago, when Dr. Baine investigated the matter. He however had not the opportunity to sit down and work out the life history, or probably his work would have been as complete as that of Marshall Ward on Leaf Disease.

In 1887, in the month of May, I obtained my first specimen of the beetle, and I soon found that as far as the estates with which I was connected were concerned it caused greater destruction than leaf disease, in spite of their being under shade. I began a careful study of the life of the insect, and though one or two minor points are still undecided on the whole of its history is fully worked out.

In the central district of the Bamboo the beetle appears later than in the hot Eastern, but sooner than on the Ghats.

My remarks apply to the central district.

After the first or second week in June, depending on the monsoon, the beetles disappear. Stragglers are to be found all the year round, but it is not till the end of August that there is any certainty of finding specimens of the autumn flight, and it is well on into April before the spring host appears.

The maxima are two: one at the end of May, one at the end of October; the minima occur in January, February and July.

To make the influence of the weather on the beetle's development clear I append a table drawn up from personal observation:—

Month.	Weather.	Temperature; deg. deg.	Beetles.
January	Dry	60 to 90 Fh.	Very scarce
February	"	60 to 90 "	"
March	Showers?	55 to 90 "	Scarce
April	Showers	68 to 90 "	Few
May	"	75 to 90 "	Plentiful
June	Monsoon	60 to 70 "	Few
July	"	60 to 70 "	Very scarce
August	"	70 to 80 "	Scarce
September	Heavy showers	65 to 90 "	Few
October	"	65 to 90 "	Plentiful
November	Showers?	70 to 85 "	Very plentiful
December	" ??	55 to 85 "	Few

Where a note of interregulation follows weather remarks it means the showers are uncertain. There is occasionally a much greater variation in the temperature than that given: for instance in May I have known the thermometer to be over 104 deg. in the shade, and I have in January seen it down to under 40 deg. F

Broadly speaking the temperature represents the averages of the maximum and minimum observations, and they do not as a rule vary in South Coorg more than five or ten degrees from those given.

A consideration of the foregoing explains why 'shade,' recommended by Dr. Bidie, who saw its good effects on the Polli Bettas where it had been planted by Mr. Minchin, who I am informed saw its good effect in Munzerabad, is so useful in retarding borer development.

The mean minimum temperature must not fall below 65 deg. F., or the development of the beetle is retarded, and shade by shutting out the sun's rays lowers the temperature.

The eggs if kept at a temperature of 38 deg. for 24 hours are all killed, few resist a temperature of 40 deg.; but if the temperature is maintained at from 80 deg. to 90 deg. almost all the eggs will give forth larvae in about 10 days. Hence when a very dry season with hot east wind occurs "borer" failures are more numerous. It is also the reason why borer has been so much worse in the "Bamboo" districts than in the forest and ghats, and is the chief reason for shade becoming necessary in the hot eastern districts.

The beetle when depositing its eggs selects a crack or crevice on the sunny side of the tree, and avoids the side upon which the monsoon rain beats. Every shower of rain destroys the eggs which have not been so placed that they are kept dry. Shade does great good by retarding the development of the eggs, so giving the trees a greater chance of being freed by the rain from them.

To satisfy myself as regards the influence of moisture I conducted a series of experiments on the development of the eggs, which I will briefly describe.

Twelve "borer" trees taken out in May were chosen for the experiment: they were as equal as possible in size; the primaries were out off.

No. 1. Four of the stems were placed standing in a dish, with soil up to the old ground level, on the top of each was placed a pad of wool. The whole was enclosed in a muslin cage which was kept about one foot clear of the trees. No. 2 was the same as No. 1, only the pad of wool was omitted. No. 3 was the same as No. 2. In Nos. 1 and 2 the soil was kept constantly damp, and in No. 1 the pad of wool also; No. 3 was quite dry. Previous experiments had shown that a temperature of 80° was most favourable to the development of the eggs, and I maintained that temperature as nearly as possible.

No. 1	was damp all over
No. 2	" " at the root
No. 3	" " dry

A beetle escaped from one of the trees in No. 3 in August, and in September I cut up the trees with the following results:—

Trees brought in May 13th, 1888. Trees cut up Sep. 9th, 1888.

No.	Larvæ.	Pupæ.	Beetles.	Totals.
1	20	3		23
2	63	7	1	71
3	191	12	3	206

The average per tree is				
No.	1	2	3	
	5.75	17.75	51.50	

This shows that a tree left lying on the ground during the monsoon, when it is kept constantly damp, does not develop many beetles, but such a tree if left out during the dry weather will develop almost all the eggs deposited on it. This points to the urgent necessity of burning the trees as soon as pulled out.

The greatest number of borers I found in one tree was as follows:—

Tree taken out July 8th, 1887, out up September 8th.

60	Borer Grubs, or Larvæ
22	Pupæ
1	Fly, Beetle or Imago

83 total in the tree in various phases

of development. One beetle escaped before I cut up the tree, so that there were altogether 84 "borers" in that one tree.

This tree was kept carefully dry, and at an equable temperature varying from about 65° to 80°.

Under favorable circumstances the life history is as follows:—

The beetle deposits the eggs in a crevice of the bark on the sunny side of the tree; in about ten days the larva hatches out, but it may require 15 to 20.

The larva works on its side and cannot advance unless there is a resistance behind: this the newly hatched insect obtains from a projection or corrugation of the bark; in 24 hours or less the creature is buried under the bark. Once in the tree it advances, compacting the sawdust-like matter it excretes by admixture with a gummy substance which aided by the pressure of the insect forcing itself up against the wood it is devouring becomes almost as hard as the surrounding wood, and fills the tunnel behind the advancing larva. This work goes on for from three to five months, when having reached its full development the larva having advanced to within about 1/4 inch of the bark undergoes transformation entering the pupa state. In this state it is covered by a thin transparent envelope, and lies with its head towards the dark and the tail towards the centre; it remains in this state till the temperature is suitable, probably about three weeks or a month, when it undergoes its final change to the beetle which eats its way out. If the larva has not worked near enough to the bark before changing, the beetle may fail to escape, there being more wood than it can consume.

From egg to beetle the average duration of the individual life is about six months, the majority of the race developing in May and October.

As I have already exceeded my limit I must conclude, though I have omitted a description of the Beetle and Borer Grub, and merely given an outline of the most important facts.

WILLIAM PRINGLE, M.S.C.I., Agricultural Chemist.
Bangalore, 3rd July 1891.

PART II.

This paper gives a description of the Holometabolic insect, the habits of which were described in my last article.

The beetle is classed with the great natural division of insects the *Mandibulata*. It belongs to the order *Coleoptera*, suborder *Arambycida* (*Longicornia Latreille*) of which there are according to Lacaze about 4,000 named species, all more or less destructive wood borers. Of these the genus *Clytus* to which the coffee borer belongs is well known in England from its representative the Wasp Beetle (*Clytus arcticus*), the larvæ of which do not however cause much loss, chiefly confining themselves to old posts and dead timber. In America there are several species which do great damage: of these *C. pictus* the hickory tree borer and *C. robinii* the locust tree borer resemble in shape and size most closely the *Clytus coffeophagus*, the Coffee Borer. But there are several important differences between them not only in the marking of the elytra, but in their shape also. They do not quite cover the body which extends about one-twentieth (1/20th) of an inch beyond them. When closed over the wings the posterior extremity is almost square across, on the outside of it a small spike projects.

Further differences between the Coffee Borer and other known species of *Clytus* will be discovered by carefully reading the following description of the insect, and comparing it with the description of named species.

The ova (egg) is cream-colored, and is just large enough to be visible to the naked eye.

The larvæ are when full grown about one to one and a quarter inches long, about two-tenths (2/10th) in diameter at the anterior extremity of the body, tapering gently down to fifteen one-hundredths (1/150th) at the posterior. The body is divided into eleven segments, humped on the back to

wards the tail, but flattened at the anterior portion. The head proper armed with powerful jaws is placed in the centre of a half-sphere, and is an obtuse knob, about five-one-hundredths (.050) of an inch diameter and projection. The underside of the body for the first four segments from the head about three-tenths of an inch (.300) is quite flat, the divisions between the segments being almost *non est*.

The last four segments are developed into knobs with a slight indentation parallel to the axis of the body, dividing each one forming rudimentary feet.

From point to point the last two segments are about one-tenth of an inch apart when the creature is at rest, it can, however, bring them together or extend them to about two-tenths (.200).

The humps on the back are not exactly opposite those beneath, but are placed on the half-inch, so that a side view suggests a screw. The tail is a protuberance on the last segment, it is about two one-hundredths (.020) of an inch in diameter and projection. Counting head and tail there are thirteen segments.

Pupa: the colour is a yellowish white, which becomes darker as the insect approaches its final change. A well-developed specimen measured sixty-five one-hundredths (.650) of an inch in length, but some are only (.500) half an inch long.

The elytra are folded under the second pair of legs and overlie the third. The antennae are carried back over legs and elytra and extend back as far as the posterior portion of the wings which are overlain by the former of the second pair of legs.

The whole is enclosed in a transparent membrane through which the form clearly shows, all the details of the future beetle being discernable.

The beetle (imago) perfect insect.—The female is a little larger than the male, measuring from fifty-five (.550) to sixty-three (.630) hundredths of an inch in length, while the male is only from fifty (.500) to fifty-five (.550). Dr. Bidie gives a good drawing of the insect in his book.

The following is a description of the female; it applies also generally to the male, only as before stated it is smaller. The head is depressed, small, flattened in front, with two white grey lines, formed by minute hairs, extending from two roots of the antennae past the eyes. These are large, prominent, brilliant, compound lenses; about forty-one thousandths (.040), and fifteen (.015) to twenty (.020) thousandths of an inch in diameter.

They are placed more to the side than to the front, just below the antennae, forty-five (.045) thousandths above the mouth. They command a very wide field of view, the insect practically seeing all round at once.

The antennae are two hundred and fifty (.250) thousandths to sixty (.200) in length; filiform (resembling a piece of black silk thread); eleven-jointed, covered with microscopic hairs incurved and pointed at the tip. The first joint is heavier and stronger than the rest; the second longer; the joints taper up towards the head, this being nearly twice the diameter of the joint which fits into it.

The mandibles are forty-four thousandths (.044) long, thirty-three thousandths (.033) broad at the base, very powerful, incurved at the point, which is blunt and rounded; each one when dissected out is in shape like a boar's head, the snout being curved down; they are sparsely covered with bristles.

The back of the head is black, polished, and smooth with minute, concave, rounded indentations; it is free from hair. The pro-thorax is one hundred and twenty thousandths (.120) long on the underside one hundred and eighty (.180) on the back, one hundred and sixty (.160) in diameter; it is when dissected out nearly spherical, a portion being out off at one end to allow of junction with the head, the other end is also sliced off for attachment to the meso-thorax. It is covered with minute yellowish gray hairs more particularly noticeable on the underside, and is marked on the back by three black spots the centre one being four to five times the size of the outer ones, they are just the size of these full stops . . .

A pair of short strong legs spring from the posterior portion of the pro-thorax, they are four tenths (.400) of an inch long.

The feet are armed with hooked bifid claws; the femur (thigh), in color black brown, is remarkably well developed. The meso-thorax is very short and wedged in between the pro- and meta-thorax giving just room for the free attachment of the second pair of legs. The meta is in shape ovoid; on the underside from the termination the pro-thorax to the anterior extremity of the abdomen is two hundred thousandths (.200) of an inch. On the back the meso- and meta-thorax are covered by the elytra, when the insect is at rest. They are in color black-brown under the wings. On the underside they are covered with a dark gray down; two lines one on each side of a yellowish white color, extending from just below the anterior extremity of the elytra, almost on the division line of the pro- and meso-thorax to the second pair of legs, from which it curves backwards over the meta-thorax to the third pair.

The second pair of legs leave the body at the posterior portion of the meso-thorax close to the first pair, they are four hundred and thirty thousandths (.430) long.

The third pair arising from the posterior portion of the meta-thorax, have the femur particularly well developed, it is twenty (.020) in length, and as with the second pair, of a light brown color. The total length of the leg is six hundred and twenty-five thousandths (.625). All the tarsi (feet) are armed with claws, and are black in color; those of the first pair are hooked, those of the second and third straight: this giving the beetle great power of holding on and foraging itself against the wood itself it is devouring. The short stiff hairs on the limbs enable the insect to clean itself; the great length and strength of the third pair of legs enable it to jump a considerable distance and as it springs off it often unfolds its wings. It seems to be all eyes and ears and is as active as a flea and requires no little skill to catch it.

The elytra (wing-sheaths) spring from the meso-thorax; they are thin horny plates, covering the wings proper; they are four-tenths (.400) of an inch long; from shoulder tip to shoulder tip two-teeth (.200) broad, tapering gently down to fifteen one-hundredths (.150) of an inch at the posterior extremity, which is squared off. A spike projects about eight one-thousandths (.008) of an inch on the outer extremity of each one. The marks on the back of the elytra are a bronze color, on a black background. Beginning at the anterior extremity they consist of a cross line about two one-hundredths (.020) broad extending right across the back. It has a small, bright-yellow spot in the centre.

Resting on the outer extremity of this cross line are two dashes which with it forms a bracket  between the horns of which a  with a minute curved top is inserted. The horns nearly touch the enclosed angle at the top of the . The bottom of this almost rests on the yellow spot in the centre of the cross line from this point to the top of the  is fifteen one-hundredths (.150). Posterior to this is a shorter  much flattened and spread out at the top, which has the point coincident with, but twenty-three one-hundredths (.230) from the yellow dot.

A wedge of bronze color measuring one-tenth (.100) of an inch base to apex, completes the marks on the elytra the base extends from spike to spike.

The wings when the insect is at rest are carefully folded under the elytra; they are rather square at the top, tapering in a beautiful curve to a somewhat rounded point.

The length from the junction with the body to the extreme tip is four hundred and forty-eight (.448) thousandths of an inch, and the extreme breadth is across the top one hundred and fifty-five one-thousandths (.155).

They are thin transparent iridescent colorings. The midrib of the wing is very powerful, it ends in a  shaped piece which enables the insect to extend or fix the wing at will, it is aided by another powerful rib at the anterior extremity. The outer edge is fringed with minute hairs which are also spread over the upperside.

The abdomen is divided into five segments marked with lateral yellowish grey lines. It tapers off gently

THE MAGAZINE

OF

THE SCHOOL OF AGRICULTURE,

COLOMBO.

Added as a Supplement monthly to the "TROPICAL AGRICULTURIST."

The following pages include the contents of the *Magazine of the School of Agriculture* for August:—

THE "CINGALEE" I. THE SINHALESE PLOUGH.

A good deal of discussion has resulted from Dr. Voelcker's commendation of the Indian and Sinhalese system of "scratching the ground;" and against this

retical view the Madras papers have quoted the practical data given by Mr. Sewell, the Collector of Bellary, who is about to undertake a series of tests to prove the advantages of deep-ploughing. The *Times of Ceylon* in an article on "Deep v. Light Ploughing" asks: "What have Mr. Green and the various Agricultural Instructors to say to Dr. Voelcker's theory? We know that the experiments made by Mr. Green all went to prove the superiority of his methods, but this may have been due to other things than the deep ploughing with European ploughs, such as the methods of sowing, &c."

Now in the experiments referred to, there were a good many in which cultivation was carried on according to the native system in every detail, except that the improved plough was used in preparing the land—the method of sowing being the same as that adopted by the native cultivator. The results of experiments with the "Cingalee" plough have been embodied in a pamphlet which is a summary of reports from authentic sources. In this pamphlet the following experiments were carried out to test the advantage of using the improved instead of the native implement, no other change in the ordinary cultivation being made; no "transplanting" being done, and no manure used:—

At Minuwangoda, 32½ bushels an acre were got by using the improved plough against 17½ bushels by working with the native implement; at Mullattivu, 28 bushels an acre against 14 bushels.

At Nikaweratiya, the Agricultural Instructor realised about 53 bushels per acre after using the improved plough—the neighbours getting 5 to 6 bushels per acre.

At Galle and Batticaloa, Mr. Elliott reports 28½ and 47 bushels per acre were taken in after the use of the improved plough.

At Toppur the Instructor took in about 23½ bushels after the use of the improved plough, only getting 14 bushels per acre with the native implement.

On another occasion the crop realised at Toppur after using the 'Cingalee' plough was 36½ bushels per acre.

Of course where "planting out" was practised in addition to the use of the improved plough the yields were much higher than where the seed was at once sown broadcast. Many of the results given in the pamphlet mentioned above, were obtained not only by Government Agricultural Instructors, but also by private cultivators; the reports being in every case perfectly reliable: so that the superiority of the improved method of ploughing over the "scratching of the ground" cannot but be acknowledged.

The deeper ploughing as well as the turning over of the soil results in the bringing to the surface of a part of the lower and inert soil which is not reached by the native implement. This turned-up soil, under the influence of the atmosphere, improves vastly in character; while after being moved and softened it becomes capable of retaining water and less liable to damage from a sudden deficiency of irrigation water. Though deep ploughing may not always give a great increase in produce the first year, it appreciably increases the output in succeeding years. There are of course soils that will not bear deep ploughing, such as those which have a sterile substratum below a few inches of good soil, a subsoil which under any circumstances it is not desirable to bring to the surface. Of course any one who knows anything of the character of soils will be able to use his judgment in

the matter of ploughing. The usual course adopted where the surface soil overlies one of extremely poor character is to use a subsoil stirrer which, while it moves and loosens and, through the agency of water, aerates the subsoil, does not at the same time bring it to the surface.

Dr. Voelcker hints that the result of the use of an English plough will be that the furrow slices will be baked as hard as brick. The rule adopted in ploughing up paddy land with the improved implement is to plough *when the land is dry*, about six weeks before the usual ploughing time. The dangers of putting a heavy implement on stiff wet land, and ploughing deep, are well known, but given that such land is well drained and dry, "baking" of the furrow-slices, or the "poaching" of the land need not be feared.

It is of the highest economic importance that the cultivator should improve and add to his soil by working to a proper depth and not merely scratching the surface of his land. While advantage is taken of silt brought on to the land by irrigation water, it is a palpably weak system which wilfully neglects the improvement of land, and solely depends upon irrigation waters (that are liable to fail) for a few inches of transported soil.

We shall look forward with interest to the official report of Dr. Voelcker, to see whether he will give any well-grounded reasons (which he has hitherto failed to do) for the statement he has made that there is no room for improvement in native agriculture in India and Ceylon in the matter of ploughing: for this statement is directly opposed to the results of experiments both in the Empire and the Island.

OCCASIONAL NOTES.

We have to acknowledge with thanks the receipt of the July number of the Richmond College Magazine. Among other interesting matter is a column of curiosities, in which mention is made of the insectivorous *Drosera*, amphibious fish, and the phenomena known as "fish-rain." *Drosera* is not uncommon in the marshy portions of the Cinnamon Gardens of Colombo,—as is also the Pitcher, another insectivorous plant. Darwin has described both these, and noted experiments made to test their power of digesting animal matter, in his work on insectivorous plants; but the insectivorous nature of these plants has quite lately been questioned by some scientists. The fall of fishes, apparently from the clouds, is an instance, of the "præter-natural rains" which have caused great consternation among ignorant races. Other examples of præter-natural rains are "blood rain" and "black rain," due to the solution of very fine desert or volcanic dust that has been carried into the upper regions of the atmosphere, "yellow rain" or "sulphur shower" due to the presence of the pollen of the Scotch fir, "wheat and manna falls" resulting from wheat or esculent lichens being carried away by hurricanes, which have also caused falls of fish, frogs and molluscs. It is recorded by Geikie that many thousands of herrings fell near Edinburgh in 1817; and that similar showers took place near Loch Leven in 1825, in Rosshire in 1828, and in Ulva in 1830. These are all due to the effect of strong winds. The fact that these hurricanes are generally

accompanied by thunder and lightning may account for the fact mentioned by the writer of "a few curiosities" that some ignorant races connect these "fish-rains" with electric phenomena. By curious coincidences falls of manna are said to have taken place at Ooromiah during a famine in 1829, and again at Herat while that place was being besieged.

In the *Nineteenth Century* for June, Prof. Huxley, in a postscript to his article entitled "Hasisadra's Adventure," referring to the "overthrow" of Darwin's theory as to the origin of coral-reefs, which, according to the Duke of Argyll was patent to every unprejudiced person, goes on to say that he has recently become acquainted with a work, in which Dr. Langenbach, a really competent authority, thoroughly acquainted with all the new lights which have been thrown upon the subject during the last ten years, pronounces the judgment; firstly, that some of the facts brought forward by Messrs. Murray and Guppy against Darwin's theory are not facts; secondly, that others are reconcilable with Darwin's theory; and, thirdly, that the theories of Messrs. Guppy and Murray "are contradicted by a series of important facts." In an early issue of this Magazine we noted the two theories of Darwin and Murray as to the origin of coral reefs and islands. Darwin has been thought by many to have assumed too much when he premised a general subsidence of the sea-floor: Mr. Murray's theory depended on facts elicited during the celebrated voyage of the *Challenger*,—facts which did not support the "general subsidence" of Darwin. When, however, so competent an authority as Langenbach avers that some of these facts were *not facts*, and that the theories of Murray and Guppy are *contradicted* by a series of important facts, it would seem likely that modern geologists will think of shifting back their belief to Darwin's theory.

Mr. T. B. Kehelpanala furnishes the following interesting notes regarding the well-known Maturajawela fields:—The name Maturajawela literally signifies royal-pearl-fields; and the place has been long associated with fertile paddy lands. Tradition says that the name owes its origin to the following incident. A Sinhalese king owned these fields in days of yore, and during his proprietorship, a cultivator—for reasons not very evident—sowed the land with the husks of paddy from the *Kalanita* or threshing-floor. Contrary to all experience and expectation, the ears of corn, instead of bearing at least paddy, carried strings of pearls on the panicles. The cultivator, overjoyed at the strange result of his experiment, went with all speed to his Sovereign and communicated the fact to his Majesty, who accompanied by his nobles lost no time in inspecting the field in question. All saw and were struck dumb with wonder at the sight. The late Mr. Advocate Muttiah gave me a very good explanation of this parable, which he thought was intended to show the extreme fertility of the Maturajawela fields, that were capable of producing, with a sowing of a quantity of seed that was hardly appreciable, a harvest as valuable as pearls. A part of these lands is now under paddy, and notable among the cultivators is Mr. Jacob de Mel. This enterpris-

ing gentleman has taken effectual measures to cope with the great difficulty in the way of cultivation, and that is the periodic influx of brackish water. During the Dutch Government dams were constructed to keep off the salt water from inundating the land. It is hoped that the long deferred project of draining these fields will result in the recultivation of the greater part of the land that has been lying fallow so long, and make it prove worthy the name it bears.

Mr. J. A. Kodippilly writes:—Para-hera and Kekuna-dure are two villages about 7 miles from Matara, on the road to Hakmana and Dikwella. Their distance from the sea is about 2½ miles. The soil is a very good loam, mixed with a considerable quantity of gravel. Coconuts and Citronella grass thrive very well. There are estates belonging to Wellabadapattu Mudaliyar, the Mohotty Mudaliyar, Dr. Schokman, Mr. D. W. Gunaratna, and several others. Almost all are cultivated with coconut. One proprietor cultivated tea as an experiment, which proved unsuccessful: 5 out of 10 acres having been an utter failure. Cinnamon is also, I hear grown in one or two estates.

W. A. D. S. contributes the following note on Chaya Root (*Oldenlandia Umbellata*):—The plant which produces the Chaya root of commerce grows wild over many parts of the Island, and is specially met with in Mannar, Jaffna, the Northern Islands and the Wauni Districts. The roots when bruised have a yellowish colour, and were valued as a good dye stuff by Indian dyers. Large quantities of Chaya root were exported to India some fifty years ago, but the quantity has continued to decrease of late years, till the last year's Customs returns showed no exports at all. Chaya is never cultivated, and it is believed that when it is cultivated the root loses to a great extent its value as a dye stuff: only an inferior dye being obtained from cultivated Chaya. The want of a demand at the present day for this dye, can only be supposed to have been brought about by the gradual displacement of the vegetable colours by the cheap aniline dyes prepared from coal tar. The quality of the Chaya depends to a great extent on the soils in which it grows: Chaya growing in the Island of Karativoe was considered to be superior in quality to that growing in Munaar or the Wauni. The digging for the root was carried on by a particular caste of Tamils.

INDUSTRIAL DEVELOPMENT.

The problem of Industrial Development is one that Ceylon has already had to face, and one that will increase in importance as year succeeds year, and the conditions of commercial life become harder and harder. It is a question the significance of which cannot be over-rated. How to develop the industries of the country, and thereby not only elevate its commercial status, but also add to the wealth of its people, and bring a comfortable livelihood to numbers that already find it hard to live,—these are problems which, if they are not pressing now, will become so at no distant period that these problems have already forced themselves on public attention is clear from the great interest excited over the Technical Institute

about which so much was said some time ago. It may not be unfair to ask what has resulted from the excitement which promised so much.

The question being so interesting in itself, it is well worth observing what other countries are doing in regard to their own industrial development, as the experience of others may be profitable lessons for ourselves. A special interest attaches to the attempts made by our neighbours in India. To one of these it is the object of this paper to call attention. A lecture was given at Lahore early this year by Mr. J. C. Oman, F.C.S., F.L.S., the Professor of Natural Science in the Lahore Government College. This lecture is one so free from mere technicalities, that it may profitably be read by even that fastidious person known as the "general reader." Its aim is eminently practical. It abounds in useful suggestions, that are none the less useful for being quite obvious when plainly stated; and these suggestions are brought before us in simple and direct phrases that make the lecture a pleasant one to read. Besides, it is not the production of an ordinary theorist, such as Professors are commonly reputed to be. The present writer has personal knowledge of the earnest efforts made by Mr. Oman for the advancement of Science, and the spread of scientific habits in the Panjab. He has among other things established a society for the cultivation of Science. One result of this lecture may be seen in the fact that a meeting was held at Lahore last month to form an Association with the object of improving the material and industrial resources of the Panjab.

With these introductory remarks we may turn to the lecture itself, of which what follows is mainly a summary.

Mr. Oman holds that the "actual position in the scale of nations occupied by any country depends primarily upon the intellectual and moral condition of the people generally, *i.e.*, upon the intellectual status of the average man in the country, not of a mere class or section of the population; and not less so upon the *character* of the average man, as regards honesty and industry taken in their widest sense." Excluding, then, geographical and climatic peculiarities, the conditions necessary for advancement are these:—(1) a stable Government; (2) General Education or national culture, including the education of women; (3) Technical knowledge; (4) Industrial association and industrial literature; (5) A market for the industrial productions of the country; (6) Capital, co-operation, and the quick circulation of money. The present lecture confines itself to only three of these conditions, the second, third, and fourth.

And first as to *General Education*. The differences between England and India in this respect are brought out in a striking manner. With a population of 250 millions in India only about 3 per cent can read and write; in England the percentage is 87, and in Scotland 93! But the contrast is not in the figures only. If in a backward district of England only 15 per cent of the population can read, and in an advanced district of the Panjab the same proportion holds, the two peoples cannot yet be considered as being on the same intellectual level. For each possesses a different literature. The Englishman has in his power to read all the latest and best ideas on

every subject of importance, whether Literature, or Science, or Art. He knows all about the most recent inventions, and has particulars of every important industry. But the Panjabi has nothing of this in his vernacular. He has "very little of any kind to read, still less that is good, and nothing at all of a practical character and conducive to industrial progress."

If it is easy to object that the educated Panjabi has also access to the Englishman's resources. But the educated Panjabi is not the average man of the district, and as a rule the educated Panjabi disdains industrial pursuits, or has no suitable opportunity of following them. Apart from that, the objection is based on a fallacy. In the first place, English is more or less a foreign language to the native of India; and in the second place, to say that the Englishman and the Panjabi have equal facilities in the way of procuring technical information is to exaggerate the capabilities of Indian booksellers.

Evidently, therefore, a national literature must be the first step to industrial advancement, and Mr. Oman appropriately proceeds to sketch the character of the literature best adapted to India. With little or no modification, it would be a literature extremely suitable for us in Ceylon.

1st. The best English works of the day should be locally procurable and at low prices. This is a subject important and considerable enough to require separate treatment. It is curious that in spite of all the concessions granted by the Government (in the way of reduced postage rates and the absence of customs charges) the cost of books should still be so excessive. Not many years ago, before the rise in exchange, native booksellers in India were able to sell most books at eight annas to the shilling. Even now they sell at nine, and the larger European firms at ten annas. But in Ceylon, we are charged 87 cents (=14 annas) for a little shilling primer, and for other books in much the same proportion! If these charges do not appear extravagant to the book-buying public of Ceylon, they certainly deserve to pay.

But even a charge of eight annas to the shilling has been recognized as too high for the natives of India and even for most Europeans. Hence it is we see special editions (like Macmillan's Colonial Library) being published for their benefit. An extension of this is what those interested in the national culture of India desire. There was lately some discussion on the subject, but nothing definite has apparently been decided.

2nd. Mr. Oman is not satisfied with cheap English books. He urges the importance of a vernacular literature. This vernacular literature may consist even of borrowed materials; but it must be national, and endowed with a healthy vitality." It must be broad and tolerant, including not only technical works, but works of imagination, history, and philosophy. Something yet is necessary,—illustrated books for the young. When we see magazines like the *Boy's Own Paper* and the *Girl's Own*, it seldom strikes us that those to whom English is a "foreign" tongue have no opportunity of enjoying or profiting by periodicals of that class. "The Indian school-boy, with nothing but his few meagre school-books to pore over, is certainly very much to be pitied, and though he may get through the examinations for

which he is prepared by his teachers, he has undoubtedly lost, and lost irreparably, an important part of the education that European children enjoy, and he has certainly missed a deal of innocent pleasure which would have been his portion under happier circumstances."

3rd. The means of illustrating books and papers should be made available. For this, lithography, wood-engraving and photography should be encouraged. "When there is in Europe such a wealth of means, such a choice of beautiful processes for the illustration of books, it seems to me a SHAME that we in India are so utterly deficient in this respect."

Then there is *High Education*. In England, Chartered Colleges, Institutions, and Examining Bodies of the highest class exist quite distinct from the nine Universities. Besides these, the Government itself undertakes an extensive system of Examinations in Science and Art. To encourage these subjects it offers grants, and even pays the Teachers, on the results system. In 1887, there were 103,362 students under instruction in this way, and the grants paid amounted to £88,000. Then, there are *Night Schools*; *Learned Societies*, with their *journalists*, *prizes*, and *medals*; and *Public Lectures*. These methods are fully treated in the lecture before us, and many practical suggestions are made, which may be referred to as occasion arises.

After General Education, the subject of Technical Instruction demands attention. There is one important feature to be noted in the agitation for special knowledge in England. There it is a spontaneous cry, a demand that has come from the working-men themselves and from employers of labour. Until this spontaneity is noted in India (let us add, Ceylon) no movement in that direction will be useful. Here is a passage from the lecture, which puts the case forcibly:—"It will not be enough for the advancement of Indian industries that a few workmen here and there should be taught certain more or less modern technical processes, processes which might be superseded any day by better and cheaper ones. For sound and permanent progress, it is essential that there should take place such a general raising of the entire intellectual level of the working classes as will place them in a position to appreciate and adopt new methods of work as they arise, and to understand the bearings of new inventions upon their own trades and crafts. They must have that living interest in scientific, mechanical, and other inventions and discoveries which characterise the employes of labour, and the better portion of the working-men of Europe and America to-day. A new class of educated masters, employers of skilled labour, must also come into existence here, before Indian industries can be developed to their fullest extent, and this will not take place until members of the better educated classes shall devote themselves to industrial pursuits, and shall not be ashamed to be the foremen of shops and the working heads of industrial undertakings, large or small."

India is mainly an agricultural country; hence agriculture is the department in which more technical knowledge is specially required. Mr. Oman does not sympathise with the European traveller who goes away with a favourable impression of the knowledge and skill possessed by

the India Balbus and Cains of the fields. Such a traveller, he says, "loses his orientation," and admires what he cannot understand. *Orientation* is a sufficiently good word for argumentative purposes, but Mr. Oman is quite clear as to the need for improvement in agricultural affairs. There must be more knowledge of the fundamental principles of agriculture. The farmers must be "set thinking along correct [i.e. scientific] lines," and "stimulated to work out improvements for themselves by learning what is done elsewhere," besides learning the "possibilities of science in its application to agriculture."

But agriculture is not all. Among other subjects which may usefully engage the attention of the educated community, there are: the introduction and acclimatization of foreign fruit trees and useful plants; dairy farming; bee-keeping; sericulture; and pisciculture. Mr. Oman has also a word to say on the need for *accurate finish* of workmanship in regard to pottery and work in metals. But it is time to bring this paper to a close. Surely in all these matters, there is a great deal that we in Ceylon may profitably take a note of. India is a vast country compared with Ceylon; yet even here there is room for industrial progress which shall be, as Mr. Oman quotes:—

"Built of furtherance, and pursuing;
Not of spent deeds, but of doing."

BEL.

AGRICULTURAL LITERATURE AMONG THE ANCIENT INDIANS.

(Concluded.)

By W. A. DE SILVA.

In the course of the chapter on Gardening in the Brihat-Samhita, referred to in my previous papers on the above subject, the author gives certain prescriptions and methods to induce cultivated plants to assume various forms which are abnormal to them. These instructions in other words intended to bring about certain monstrosities in plants, such as would make them more valuable as food products or ornamental shrubs. To quote the writer:—

"To produce fruits of a very large size which are devoid of seed, soak the seed of the pumpkin, or of the brinjal or of the snake-gourd &c. in the serum of the fish or hog and dry the seed. If the seed be then sown in good soil and watered, it will bear fruits of very large size and without seed."

Again:—"Make cakes of a mixture of sugar, rice flour, and Mahwa (*Bassia Latifolia*) flower buds, and cover with the cakes the roots of fruit trees throwing earth over the parts. The fruits will grow without seed."

It is a well-known fact that in most fruit trees without seed and consisting wholly of pulp are met with. This end is sometimes gained by the process of high cultivation, when the edible cellular tissues in the fruits develop to an abnormal extent, while at the same time the seeds tend to diminish in number and size, and finally to disappear. From this, however, it is at least clear that as seedless fruits are naturally met with in trees, and especially when under high cultivation, it is not improbable that they could be produced by artificial means.

Among some rules for the cultivation of ornamental plants is found one which is said to cause the production of many-coloured flowers in the

white waterlily. "Thrust the root of the *Kumuda* (white waterlily) into a solution of a variety of colours, soak the root of the plant in urine, rub over it ghee and honey, and sow the seeds that are produced. They will grow and bear flowers of the several colours in which the root of the original plant was soaked."

Now I shall proceed to give a few startling examples of rules we find in this ancient agricultural work.

To make trees grow like creepers: "Mix together the flour of rice, black gram, and of sesamum seeds, with the flour of barley, dead or decayed flesh, and a small quantity of water. Soak the seed of the Tamarind in the mixture and expose it to the smoke of the root of the turmeric. The seed when sown will grow as a creeper."

Again:—"Dig a pit in the ground a cubit square and two cubits deep, and fill it with a solution containing the extract of the flesh of the fish. Allow the pit to dry, helping it to get rid of the moisture by means of fire. Rub the sides and bottom with a mixture of honey, ghee and ashes; fill the pit with the flour of black gram, sesamum seed, and of barley mixed with earth: pour over the pit the 'fish-water,' and pound the mixture well till it becomes hard. Sow any seed at a depth of four inches and water it with the 'fish-water.' The seed will grow as a fine creeper, with tender leaves over terraces and the roofs of houses in a most wonderful manner."

"If the plaintain," we are next told, "be watered with a liquid mixture consisting of the flesh, and serum of man, the powdered tooth of the elephant and water, the tree will yield mango fruits."

The phenomenon of the change of taste in some cultivated vegetables and fruits by the application of certain manures is not quite new, as it has been found out by experience that when pig's dung is used in the growth of certain vegetables, it imparts a peculiar taste to them. So in all probability the special compost which is advocated above might give the plantains a flavour resembling that of the mango. But here is a recipe that beats all previous ones:—

"Soak any seed many times in human flesh and the oil of Ankola (*Alangium Herapetalum*) drying the seed each time. Take a quantity of earth in the hand, bury the seed in it, and pour water over it, the seed will grow that instant."

Now such curious prescriptions and recipes as have been quoted in this paper are by no means peculiar to the ancient Indians. Dr. A. M. Ross in the course of a paper on "Medical Delusions" in the "Journal of Hygiene-Therapy" says, that "one hundred and forty years ago Dr. Sydenham of England, called the 'English Hippocrates,' prescribed the following dainties in which he was followed by the medical profession of England: Hop lice, viper's flesh, dried human flesh, the heart of a mole, crab's eye, the excrement of sheep and dogs, powder of burnt owls and swallows, blood of black cats and white puppies, and spittle of reigning king."—(*Sydenham's Praxis Medica* pp. 151-154.)

So that if eastern pundits advised the use of peculiarly composed fertilizers for plants over a thousand years ago, western physicians have prescribed still more startling remedies for human beings less than two hundred years ago.

CEREMONIES OBSERVED BY THE KANDYANS IN PADDY CULTIVATION.

The time of ploughing is one of great solemnity to the Kandyan paddy cultivator. The *Nekatrata* is again consulted for the purpose of fixing a *nekata*.

Exactly at the time appointed the goiya puts into a large earthen vessel of water, the paddy that is to be sown. Having allowed the paddy to soak for a time, it is heaped on the cow-dunged floor in a pyramidal or conical shape. Dougonuva Bandar Ratemahatmaya of the Badulla district informed me that a peculiar preliminary ceremony was observed by the cultivators of that part in connection with the sowing of paddy:—Images of Buddha in recumbent, sedent, and erect postures are brought with every mark of solemnity to the place where the paddy to be sown is stored, and certain religious performances are gone through by the officiating Kapurata. Four days after the soaking referred to above, the ceremony of *yan karanawa* takes place, that is, the separating of the germinated seeds from the general mass. A part of the *pila* (verandah) or other convenient place is then rubbed over seven times with a thick solution of cowdung, and the paddy is placed on this prepared floor and covered over with leaves of the Habarala, Enduru or Manu. The field is then got ready for sowing and the goiya proceeds to the Astrologer to consult him as to a lucky hour and day for sowing. Very early in the morning on this day the cultivator anoints himself with sandalwood or other oil, and repairs to his field with the seed to be sown—the paddy being placed on plantain leaves and a mixture of cowdung and water poured over it. The goiya, as he sows the paddy, repeats to himself certain religious stanzas and meditates on the Hatarawaran Dewiyo, the gods of the four regions of the globe. Every precaution is taken to prevent trespass of all kinds on the field, and the goiya fences in his land with stones or sticks. Much of the time of the cultivator is now necessary for watching his field. When the paddy is about a month old weeding (*Wal Ederema*) is done. This part of the work is exclusively done by women, who are required to be thoroughly clean.

Thinning and planting or *Nehma* is done by the women when the paddy is about 3 months old. On a day which is not considered unlucky the women call upon the owner of the field for the *attakaiya*, and the owner, according to recognized custom, treats the women to *kann* and *kiribat*, and directs them to commence work. The women, while transplanting, intone verses of poetry, making pleasant music. No one dare cross the ridges with open umbrella while the women are at work, unless there be urgent need for so doing, and permission be first obtained, otherwise mud &c. are thrown on the intruder whoever he be. The President of Uda-Bulatgama mentioned to me that it is recorded of a certain king of Kandy, that while crossing a field known as Gurudeniya, in Kundasale, where some women were engaged in transplanting, he was bespattered with mud by them. The women proved themselves no respecters of person in the carrying out of their duty, while the king himself passed on without a word of

consure against the treatment which no doubt he thought he deserved.

Gampola, Angammana Adikaram Waluwa.

(To be continued.)

GENERAL ITEMS.

Mr. J. S. de Saram, late Assistant Master at the School of Agriculture, and still more lately Magistrate at Balapitiya, has been provisionally appointed Assistant Superintendent of Police of the Western Province.

At a Committee Meeting of the Agri-Horticultural Society, it was decided that the December Show should be held at the Racket Court, Colombo.

We are anxiously looking forward to the conditions of the proposed settlement under Kalawewa tanks, for the success of the project will greatly depend on the nature of the conditions.

The following is an extract from the Administration Report of Mr. Price, Assistant Government Agent of Kegalle, and contains some excellent suggestions:—

"To encourage agriculture and to foster improvement in its methods are similarly part of good government. The institution of a Department of Agriculture or of Agricultural Boards, somewhat on the lines of the suggestions which have frequently been published in the local press, is a measure which is very desirable. Meanwhile progress, if it can be said to really exist, is spasmodic instead of being regulated under the guidance of experts. An Agricultural Show now and then, an occasional distribution of small rewards by the Assistant Government Agent on circuit, agricultural instruction—confined, owing to the want of funds, which admit of the employment of only one instructor, to a restricted area—are the only efforts at present possible for local officers. More agricultural instructors are wanted, but the Assistant Government Agent has no money available for their salaries, and the movement in this direction is cramped for want of funds. Arrangements are now being made, with the assistance of the Director of Public Instruction, to station the one agricultural instructor, for whose remuneration it has been found possible to provide, at a new school close to the so-called experimental Garden of Kegalle. And it is hoped that the headmen and people who come in from all parts of the district to headquarters may profit by what they will see at this centre. But it is a mere drop in the ocean. Given a little money, and real advance would be feasible. Another thing to do is to undertake the systematic planting and careful rearing of fruit trees in public grounds, such as the premises of every resthouse and each Village Tribunal. Preparations are now being made for doing some work in this direction in earnest during 1891, and the Assistant Government Agent has secured promises of assistance from the Director of the Royal Botanic Gardens."

The Paris correspondent to the "Ceylon Patriot," gives the following as "useful to Dairymen":—"Hot water for cows" is the maxim

of the French dairy farmers in the department of Finisterre. They claim to have proved by experiments that when cows drink hot water they yield one-third more milk than when they are refreshed with cold water only. Caution must of course be observed in adopting the new system. Avaricious dairymen must beware of scalding the throats of their cows in their haste to avail themselves of this discovery, which is vouched for by the Consul at Brest. The proportions, it is said, are half a pail of boiling water to half a pail of cold water.

A Commission appointed under the Scottish Universities Act have issued a draft Ordinance abolishing the degree of B. Sc. in Agriculture at the Edinburgh University. It was through the efforts of Prof. Wallace that this University instituted the degree, the first of its kind in the world; and following it the leading English Universities are founding similar degrees. Much dissatisfaction is felt in Scotland at the action of the Commissioners, and there is some prospect of an Agricultural College being founded to supply the University course that will before long be given up.

THE TROPICAL AGRICULTURIST MONTHLY.

Vol. XI.

COLOMBO, SEPTEMBER 1ST, 1891.

[No. 3.]

THE CEYLON PLANTING ENTERPRISE : AREA UNDER TEA AND OTHER PRO- DUCTS IN AUGUST 1891.

We are now in a position to give the main results of the planting returns which have been pouring into our office for the past month or six weeks, the same being separately verified as far as possible by the estate mercantile agents in Colombo. Out of a total of 687,832 acres returned as included in the plantations of tea, coffee, cacao, cardamoms and cinchona in the island, not quite one half or 333,953 acres are given as under cultivation. Of this latter area, the total under tea alone is 287,310—or an increase of 30,000 acres of tea in the twelve months—apart from some 9,900 acres of tea planted along with coffee, cinchona or cacao,—soon we may be sure all to be tea. In round numbers therefore and allowing for clearings to be planted in the coming North-east monsoon, we may say that the close of 1891 will see 250,000 acres under tea in this island. Now considering the considerable proportion not yet in bearing, it is clear that if our total export of tea this season is to reach nearer to 70 than 60 million lb., the average yield for the districts will not be much less than 375 lb. per acre; while if the quarter million of acres are to give 100 million lb. of tea by 1894 or '5, the average will then have to be exactly 400 lb. per acre.

Turning to other products, poor old "Coffee Arabica" cultivated alone, only shows 28,899 acres for the island, apart from about 17,000 acres of coffee with tea, cinchona or cacao, and also apart from about 1,800 acres of Liberian coffee.

Cacao covers 10,597 acres alone, while over 4,000 acres more of it is interspersed with coffee or tea. Of Cardamoms about 5,000 acres are still

cultivated, the same as last year. Of Cinchona, we have 5,062 acres and 2,538,000 trees separately returned, apart from cinchona interpered between coffee and tea over 15,680 acres. Altogether we may estimate the equivalent of about 9,000 acres with cinchona or a falling-off in the past year of 6,000 acres which have been cleared and planted with tea. In June 1890, we put the number of cinchona trees over 2 years old growing in the island, at 19,677,000. Now the total can not exceed 12 million trees, and putting their average yield at 1 lb. dry bark per tree, that would show that Ceylon has no more than 12 million lb of "2 per cent bark" to contribute to the world's requirements, and if this is spread over say the next three or four years, the annual export is likely to fall to 3 or 4 million lb. If the statistical position of the Java cinchona industry could be made equally plain, we might expect to see a far more hopeful position established in the cinchona bark and quinine markets of London and the Continent of Europe.

FUEL CONSUMPTION OF INDIAN RAILWAYS.

According to the recently issued Administration Report of the Director-General of Indian Railways, the consumption of fuel on all railways during 1890 compares as follows with the consumption during 1889.

[We summarize the figures.]

English coal 224,776 tons in 1889 and 203,578 in 1890. Indian coal 583,923 and 641,443. Total coal 806,923 and 845,021. Coke 13,093 and 13,386. Patent fuel 24,560 and 18,594. Wood 331,617 and 318,731. A note to patent fuel and wood seems to indicate that the figures for 1890 are only approximate—probably below the truth. On the above figures it is remarked:—

"The total consumption of coal during 1890 was greater by 4.72 per cent, but the quantity of English coal decreased by 9.43 per cent, while that of Indian coal rose by 10.18 per cent. The total consumption of coke increased by 2.23 per cent, and that of patent fuel and wood decreased by 24.29 and 3.88 per cent, respectively.

Australian coal seems to be mixed up with English. We need scarcely remind our readers that the working of railways in many parts of India has the advantage of local supplies of coal which is not the case in Ceylon. With us only small quantities of coal are used, mainly on the steep gradients.

The total quantity of fuel consumed on Indian railways in 1890 was:—

Coal	845,071 tons
Coke	13,888 "
Patent fuel ..	18,594 "
Wood	318,731 "

Total .. 1,195,722 "

A quantity which will increase year by year, unless science makes some grand discovery in the direction of the cheap application of electric force. Such a discovery would be of immense importance to Ceylon, by setting free for agricultural purposes large areas of forest now reserved for railway fuel.

The mileage for which nearly 1,200,000 tons of fuel were consumed was about 10,000. If, as it is hoped, petroleum in quantity is discovered in India there will be in the case of the adjacent empire a double advantage over Ceylon, in two better forms of fuel than wood being available. As our own railway system extends the drain on our forests will be very serious, apart from the inconvenience of the bulky nature of the fuel which has to be transported to and on the railway. For our railway and for our tea factories our hope is in the discovery in the near future of a cheap method of utilizing the all-pervading force called "electricity."

THE RICE FIELDS OF CAROLINA.

From the "Louisiana Planter and Manufacturer"

Colonel John Soreven, a distinguished rice planter of Savannah, some four years since, in a public address, referred to a rice plantation as a "great agricultural factory." Mr. Trenholm, of Charleston, lately a prominent member of the United States civil service commission, a year or two afterward made use of nearly the same words, though evidently in ignorance of their previous employment. That authorities so high and entirely independent should mutually employ the same expression is most excellent *prima facie* evidence of its applicability and epigrammatic fitness.

And a factory truly a rice plantation is in the fullest sense of the word; for Nature—passionless stepmother that she is—exerts so slight, and attentive art so complete and watchful a control over every process attending its production, that rice is substantially "manufactured" not cultivated.

But in this instance military art lends unconsciously a wondrous beauty with its practical economics. No fairer prospect exists in the whole realm of agriculture than the landscape of a well-appointed rice plantation, whether viewed in the early spring before planting, with the swampy expanse of its embankments intersecting the checkerboard squares, the mellow mould still steaming from the plow, and the whole visible area apparently as cleanly swept and garnished as a parlor floor; or later, during the nursery reign of the foetering "stretch water," each square a lake, its wavelets rippling under the fresh sea breeze, with the tops of the young plants immersed, for forcing—in long, waving lines of tendril floating on the water and the russet banks separating like from lake, now paths of emerald, their grassy carpet blowing in the April sun; or later still, during the "long water," the entire landscape one waving sea of green, broken only by the crystal ribbons of canals and quarter drains; or finally in the full noontide of harvest-time, the level fields, now lakes no more, but vast stretches of stubble, dotted with stacks of golden grain, as if an army tented there.

The wheat fields of Dakota are impressive, but their unbroken, unrelieved monotony is almost painful. The vine-clothed hills of the Upper Ohio are novel and interesting, the velvet slopes of the valley of the Roanoke and Kentucky's blue-grass meadows pretty and attractive; but a study of the rice fields of the Atlantic deltae is simply fascinating.

In other agricultural pursuits man's efforts are the sport of the elements, and largely dependent upon the caprice of nature. In this man works with God, in the very shadow of his presence, with intelligence and judgment regulating the wayward freaks of nature, grafting chemical affinity and physical force, and directing both to an end, reasonably certain if properly compassed.

The high plane of thought necessarily traversed by the planter pursuing this avocation from generation to generation, naturally induced a broader intelligence, greater elevation of mind, superior refinement, and a more universal and thorough cosmopolitanism than has ever been attained either before or since in any other kindred employment.

Yet this incidental super-refinement was far removed from effeminacy. During the late war, whenever a crisis struck fast in the mind the first volunteer shoulder under the wheel was that of the young rice-planter, who a month previous had daintily aired himself in his spotless white-drunk suit; while Jake and Pat, the stevedore and the ditcher, invariably "stood afar off," watching the performance, nor lent a helping hand except "under orders."

The word "rice" is evidently of eastern origin; Tamil, *arisi*; Arabic, *aruz*; Latin, *oryza*; Italian, *riso*; French, *riz*. It is only second in importance among the cereals to wheat, and forms the grain food of over one-third of the human race.

Its use by the inhabitants of China and India extends as far back as the earliest records of either country. A Chinese classic describes minutely the drainage and irrigation works constructed by the Emperor Yu on the Yangtse-kiang 4236 years ago. It was cultivated in Egypt fully fifty centuries ago, though not the principal food of the latter country. Frequent biblical references to rice are found. Herodotus fully describes it, as does Pliny in his treatise upon the food plants of India. While Gibbon considers that it was cultivated in Spain at the time of the Roman occupation, it certainly, as an industry, attained no prominence in Europe until comparatively modern times, and it is generally believed to have been introduced by the Moors into Andalusia during the eleventh century, and to have crossed from Spain into Italy about a century later.

Rice is now grown in nearly every portion of the globe—in Java, Brazil, Hawaii, America, Italy, Japan, India, but principally in China and Burmah. The Burmese crop is nearly all exported, the inhabitants subsisting on some cheaper food, as millet or durra; that of China is principally consumed at home, though a good deal finds its way into this country.

Rice varies so greatly in its appearance as it does in its cultivation and habits of growth. An English authority, H. B. Proctor, to whom acknowledgment is here made for much valuable information on this subject, says: "There are far more cultivated varieties of rice differing more from each other than there are of wheat or any other of the grain foods. The Karens, a hill-people in British Burmah, have names for forty varieties. Dr. Moore mentions one hundred and sixty-one varieties growing in Ceylon, besides which there are those grown in Africa, China, Japan, and other parts of the world. The colors of the grain

vary from coal black, dark red, pink, yellow, to ivory white. The snapes are various, and differ much from each other; some varieties are sweet, others bitter; some oily, others dry; some hard and translucent, others soft and chalky. Botanists have classified the varieties into four divisions: Early rice, common rice, clammy rice and mountain rice."

Clammy rice is little known to commerce. It is said to mature its seed in five months, and to have the advantage of growing on wet or dry land.

Mountain rice grows on the Himalayas and is very hardy. It does not require irrigation, and will stand severe cold, sometimes pushing its way through the snow.

Common rice is wholly an aquatic or marsh plant. It cannot exist without water, and soon withers away if the ground becomes dry before harvest time." To this division belongs Burmese rice, and the process of cultivation is highly peculiar.

A great portion of British Burmah, in the provinces of Pegu, Arracan and Tenasserim, especially in the delta lands of the Sittoung and Irrawaddy, is very low and flat, and the rainfall excessive, amounting to 180 inches during the season. The result is that the country is flooded from one end to the other with from one to twelve feet of water. Locomotion can only be accomplished by bunt, and the inhabitants are confined to their houses. There are only three seasons, the cold, the hot, and the rainy. At the commencement of the latter, or about the end of May, the fields are prepared by cleaning them of weeds and burning the stubble, and then ploughed by dragging a species of rake or narrow over them, oxen and men, as seen in the annexed *fac simile* of a Burmese drawing, sometimes sinking ankle-deep in the soft mud. This certainly would be an accumulative procedure in our own country!

The "paddy" or rough rice is sowed some time in June, after the rains have fully set in, on the surface of the water, to form nurseries. In September, when the young plants are a foot or more high, they are "drawn," tied in bundles and carted, or rather boated off to the fields prepared for their permanent reception, where they are transplanted by hand in rows, generally by women and children, who wade about in the mud and slush like so many porcupens.

No further attention is then given the crop. It is never ploughed or weeded. The only care taken is to stop the openings or sluices—corresponding in some measure to our "bunks"—in the embankments or "bunds" surrounding the fields, thus retaining the copious rainfall to nourish and protect the plant.

In some parts of India the land is cropped three times a year; in Burmah only once. No manure is used; rotation of crops is unknown. The heavy rains all the land receives to bring forth an abundant harvest. Yet the average yield of the country is about thirty bushels per acre. In some instances it has reached sixty or seventy bushels. Still the success of the crop is very uncertain. Procter says: "Where so much depends upon rainfall, it is an exaggeration to say that an inch or so of water, more or less, determines whether the receding flood shall leave a bright and fertile plain full of promise, or a ruined waste of drowned and rotted crops. With a late and heavy monsoon thousands of acres are sometimes submerged and the crop ruined. Should the floods, however, not be too late in the season the ground is replanted a second time and sometimes a third time, and the cultivator possibly saves his harvest. * * * With an early and deficient monsoon, on the other hand, the plants are not nourished and they yield but a scanty return."

The Burmese method has been partially detailed on account of its distinctive difference from the American system and its essentially novel features. With the Burmese everything is adventitious. With us little is left to chance and only extraordinary cataclysms or other disastrous visitations of Providence affect the result; and yet these have, of recent years, occurred so frequently as to make even the American system, despite the safeguards with which science surrounds it, one of extreme hazard. Moreover, the price of labor and consequent cost of cultivation is now so great, compared with the Burmese happy-go-lucky methods, that the average cost of production per pound is greatly in favor of the latter, as will be shown hereafter.

Early rice is to us the most important of the four divisions, for it includes American rice or "Carolinias," as it is known to commerce, besides the varieties raised in China, Japan, India and Java. Japanese, however, is principally upland rice and grown by dry culture. Chinese rice, on the other hand, is generally irrigated.

And here an important distinction must be made. Common rice, or "Rangoon," as before stated, is essentially an aquatic plant; water is its life; without it, even temporarily, it withers and dies. It is sown in the water, transplanted in the water, and ripens in the water. Early rice, or "Carolinias," has also generally been termed an aquatic plant, but most incorrectly. It is in reality amphibious, if a strictly zoological term may be applied to vegetation. Like its congener, the alligator, it thrives in two elements, demanding each at its proper time and interval, and perishing if confined unduly or excessively to either.

But both rice and alligator are hardy and tough, and can withstand considerable abuse. The latter can be removed from his swamp and manage to exist in discomfort and impaired vitality for quite a while with merely periodical supplies of his favorite element. And so may rice be subjected to dry culture in this country, and, watered only by the rains of heaven, exist and produce a moderate harvest.

Under dry culture from fifteen to twenty bushels per acre is an average crop, while under wet culture the yield has sometimes reached as high as ninety bushels.

But it is not with upland rice that we have to deal. Produced from the same seed as that of the deltas, or *vice versa*, its cultivation is uninteresting, and very similar to that of a dozen crops familiar to every one, as may be seen by the illustration.*

Wet culture, however, on the Atlantic seaboard, possesses features of unusual and striking interest, and the remainder of this paper is devoted exclusively to its processes and incidents.

The oldest staples of the South-Atlantic states were tobacco, rice and indigo. The two former still survive as important industries, although cotton has usurped the principal position; but the cultivation of indigo has long since fallen into "innocuous desuetude," and few are familiar with even its appearance.

Rice was introduced into Carolina about the year 1700, a planter by the name of Woodward having obtained a small amount of seed from a brigantine, just from Madagascar, that had touched at the port of Charleston. For a long time little was cultivated, as it is the most difficult of all the cereals to prepare for food. But gradually, as methods were devised for cleaning it, and as the number of slaves in the colonies increased, it sprang into prominence, and by the year 1724 the production had reached 10,800,000 pounds. This had increased to 187,167,032 pounds in 1860, and ninety-six cubic yards per acre.

But Carolina rice, like Orleans cotton, had, during this period, forced its way to the top of the European market, was considered the choicest variety, and commanded the highest price.

Then came war and the Federal gunboats and Monitors crawled up the creeks and shells sang over the deserted quarters. Lines of intrenchments bisected the fertile fields; embankments and canals were demolished; barns, dwellings and mills destroyed; the neglected squares soon choked with reeds and sedge and saplings; and when peace finally came it found a desolated wilderness, tenanted only by the marsh-hen and the moccasin, while as overseer the alligator barked in undisturbed serenity.

Add to this the then untried and still unsolved problem of free negro labor, a motor generated of indelirium and ending in paralysis, and it will be seen that the participle demoralized will but feebly describe the condition and prospects of the rice industry in 1865. The wonder is, not that it should have failed to make greater headway in the interval, but that it should have recovered at all.

In order to fully appreciate the wrecked state of affairs at this time it is necessary to understand the physical construction of a plantation. Two modes of irrigation are employed in America—the "tidal" and the reservoir of "back-water" system—the former on the Atlantic seaboard, the latter in Louisiana. The process of cultivation in each case is similar, and they differ only in the means by which the flow is obtained.

Of late years many of the old sugar plantations of Louisiana have been adapted to the culture of rice, and it is possible, in almost any portion of that state of innumerable bayous, to irrigate more or less successfully by establishing a reservoir of back-water, to be drawn upon at the proper intervals. But the supply must evidently be dependent upon the rainfall in the up-country, and this is capricious. Nevertheless, when the water is abundant, the Louisiana cultivator has the advantage of not being compelled to wait for spring tides, but can flow his land at pleasure. The North Carolina planter, on the Cape Fear and Waccamaw rivers, where the tides were less and the land levels relatively lower than on the Savannah and the rivers south of it, also enjoys this privilege to some extent.

The rice lands of the Atlantic seaboard occupy the deltas of the rivers from Pamlico Sound, in North Carolina, to the St. Mary's river, in Georgia. They are confined in every instance to the *fresh tide-water*, the tidal flow being necessary for inundation, and the water, of course, must be free from salt.

These narrow river strips consequently extend from the extreme limit of brackish water to the extreme limit of available tide-water, a distance varying with the volume and location of the rivers. They are pure alluvium in formation, and all very similar in character. The soil, in many cases, is ten, twenty, or even thirty feet in depth to the underlying stratum of sand. Often the remains of prostrate forests, the result of ancient hurricanes, with layers of ashes and Indian remains, lie buried in this alluvium, the logs and stumps frequently so near the surface as to present a serious obstacle to the ditcher, and greatly enhancing the cost of reclamation. This must have been excessive, and only under the thorough discipline and economy of slave labor was at all possible. As a proof of this, on the whole Atlantic coast not one new rice plantation has been established since the war; on the other hand, many have been abandoned.

Taking an illustrative plantation of six hundred and forty acres or one square mile for easy

calculation, it will be found that the exterior embankment is four miles in length, and the interior embankments, along the canals and those used for roadways, as seen in the chart, about six miles more. The plantation is subdivided by lesser embankments, called "check banks," into fields or "squares," whose areas differ according to the character of the ground. Generally, the more irregular the surface the smaller the squares, some containing as many as thirty-five or forty acres, others as few as five or six. They will average, however seventeen or eighteen acres each. This adds in check banks a further length of eight miles, making the gross length of embankment eighteen miles, with gross solid contents of one hundred and eleven thousand and seventy-nine cubic yards, or one hundred and seventy-four cubic yards to the acre.

But the original cost of the embankment is greatly exceeded by that of the necessary drainage.

Colonel Scriven, who is probably the best authority on rice in the south, says: "The drainage of the rice-fields and its annual maintenance is a servitude more burdensome than their embankments. It is, however, also true, that while the rice plant of the tidal lands is aquatic, or perhaps, more correctly, amphibious, it is paradoxical in demanding the most thorough drainage for its successful growth. * * The drains imperatively require to be not only thoroughly excavated in the origin, but to be constantly kept down to their original depth, and, as the land settles, to be lowered to the same depth.

"A properly arranged plantation of six hundred and forty acres, looking to the best control of flowing water and to thorough drainage, would require four parallel canals, each twenty feet in width and five feet in depth. The total length of these would be three and one third miles. Each would require a flood-gate at its extremity on the river, so arranged as to admit or bar the tide-water at pleasure. Along these canals, one on each side of each field or two to the field, are laid small flood-gates commonly called 'trunks,' by which the watering and drainage of each field is independently regulated. The main flood-gates of the canals are frequently true locks, so that the canal and river navigation may be united. The four canals mentioned call for the excavation of forty-eight thousand eight hundred and eighty-nine cubic yards, or seventy-six cubic yards per acre.

"In addition to these canals, which are the great arteries of the rice fields, each square or field must be surrounded by a main or margin ditch out six feet wide by four feet in depth"—generally about fifteen or twenty feet off from the check bank, leaving a cultivable margin between ditch and bank all around the square—"and parallel drains, called 'quarter drains,' must be sunk through the fields one and a half to two feet in width by three feet in depth, usually seventy-five feet apart, but, in some instances, still nearer. * * The lineal measurement of this drainage will be ninety-four miles and the excavation one hundred and fifty-seven thousand two hundred and twenty-six cubic yards, or two hundred and forty-six cubic yards per acre.

Summing up, the combined embankment and drainage on this illustrative plantation of six hundred and forty acres amounts to one hundred and fifteen and a third miles, or eighteen miles to the acre, and demands an excavation of three hundred and seventeen thousand two hundred and ninety-four cubic yards of earth, or four hundred.

Some commensurate idea may thus be obtained of the immense original cost of constructing a rice plantation, or even renovating a damaged one

and also of the attendant "servitudes," as Colonel Screven aptly styles them, constantly menacing the planter. Nor is it surprising that in 1860 some rice lands were held as high as two hundred dollars an acre, and paid an excellent per cent. on that figure. Today, owing to the difference in the price of labor and the corresponding profits, these lands could be purchased for much less, and in every instance at a figure greatly below the original cost of construction.

The equipment of a rice plantation varies with its size and location. From three hundred to five hundred acres is about the average size. It scarcely pays to cultivate less than one hundred acres. On a place of average size, sufficiently near a city or town, a rice mill is now a rare adjunct. Previous to the war nearly every large planter milled his own rice, doing toll work as well for his neighbors. Now it is found more convenient to carry the rough rice or paddy by boat to the big steam mills in the nearest city. A thresher, however, is necessary on every plantation of any size. In addition to the common laborers who are employed by the day, and engaged and discharged as convenience requires, a well-appointed plantation generally has an overseer, a trunk minder, who is always a carpenter, and a foreman or "leader" for the negroes, besides a few regular hands to care for the stock, all of whom are engaged by the month or year.

As many mules are necessary as on a cotton plantation of the same size; for although at times they have nothing to do and enjoy altogether an easy life, nevertheless, when they are wanted badly and in considerable numbers, as is the case during "rolling time" in sugar planting, in order to hurry through a certain process by a given time.

The planter's busy season commences with the new year. The squares are cleared of stubble, ploughed, and harrowed. The stubble is in some cases ploughed in but is commonly burned on the land. The ditches are cleaned out annually, as they foul quite rapidly from abrasion, silt, and water vegetation; and the stuff so thrown out of the main ditches is laid on the banks. One would think that in course of time the latter would become considerably enlarged by the accumulation of vegetable matters and ditch mud thus piled on them year after year; but in many instances, so light and porous is the original soil of which they are composed, and so spongy and liable to rapid decay is the added trash, that the banks are annually shrinking and growing smaller under the process of gradual consolidation, so much so, indeed, that in even on a well-kept plantation it is frequently the case that two or more squares temporarily join their waters by portions of the bank giving way.

Single-horse plows are generally used in breaking up, but successful attempts have been made to introduce sulky and gang plows and screw pulverizers. The fields, however, are so cut up by the quarter drains that commonly light, portable bridges have to be employed in crossing the ditches, and heavy machinery, in consequence, is not always convenient. Besides, the soil, contrary to the necessity in sugar planting, does not require deep breaking.

As a rule the land is not fertilized, although it will not be long before the contrary will become the common practice. Many plantations that have been under constant culture since colonial times still yield good harvests; but the land is gradually, though fortunately very slowly, losing its native power. Usually the older fields produce rice of superior quality though less in quantity than the fresher lands.

Where a field has recently been "taken in,"

and is consequently composed of light, porous soil, it is not productive on account of the absence of mineral matter. On such a field phosphate and potash salts are used to advantage; on some of the older fields nitrogenous fertilizers are occasionally applied, but not with as satisfactory results as in other crops.

The paddy is sown from the second week in March to the middle or end of May. March sown rice will mature in about five months and fifteen days. Later plantings sometimes mature in advance of the earlier.

The principal motive of the planter, aside from important cultural objects in selecting the period of sowing, is to avoid harm upon the visitation of that vicious pest yet succulent dainty, the rice-bird. He comes in swarms twice a year—in the late spring and early fall—and the rice must be planted at such intervals as to be protected from his ravages. And here another factor comes in, available spring tides.

Both the early sowed rice and that planted later are protected by the "sprout" and "stretch" waters when the birds come in the spring. The former is harvested and safe from their visitation in September, and the latter is not fully ripened until after they have taken their flight further southward.

Should a mistake be made in regard to either of these conditions, the rice-bird to the unprotected crop is as disastrous and annihilating as the torch or a tornado. Therefore, if the planter misses one spring tide, he must wait and carefully make his calculations so as to be able to utilize another for sowing.

Before the war the variety commonly used on the coast for seed was known as "gold-seed." At that time white rice was planted almost exclusively in the interior. This has now generally superseded gold-seed, on account of its more certainly yielding a superior pearly luster, because it is more readily cleaned, and because of its earlier maturity. Bearded rice is sometimes used, but never on the tidal lands.

The process of seeding is very simple; grain drills, similar to those in use for wheat the country over, with a slight adaptation suiting them for rice, are employed. The drills are set fifteen inches apart, and the land is sowed a little more heavily than for wheat. It is a noted fact that the white rice of the uplands affords better seed for wet culture than tidal-raised seed, and is preferred by planters.

As soon as the rice is planted the "sprout water" is turned on to swell the grain and force germination. It is allowed to remain, according to temperature, from forty-eight hours to fifteen days and then drawn off.

Now comes a picnic for the birds. The grain is only slightly below the surface, soft and succulent; and crows, jackdaws, blackbirds, and sparrows know when the sprout water is off as well as does the overseer, and they flock to the fields like school-boys on a holiday.

Each square, according to size, is guarded by one or more dusky Nimrods, and from dawn to dark the constant popping of the old army musket sounds like a regular skiruish. It is nothing unusual for one planter to use eight or ten kegs of powder a year. Strange to say the negroes do not relish this employment. It keeps their attentive faculties on the alert all the time. Not for a moment can they relax their vigilance, for the birds will be down on the fields, and yonder is the overseer's horse on the canal bank, outlined against the sky, and detection will follow instantly. Your genuine darkey loves to plough; the occupation

suits him nobly; he can go "half to sleep" between the handles and yet manage to hold a pretty straight furrow. But put him at any work that requires the slightest mental exertion or is otherwise than absolutely mechanical, and he is at once out of his element and worried accordingly.

In from ten days to six weeks, according to the season and temperature, the "stretch water" is put on, and according to the exact stage in which the young sprout is at the time, is called either the "stretch from the point" or the "stretch from the fork."

The careful planter always endeavors to stretch from the point. It is well known that in all vegetation certain roots and sets of roots beneath correspond with certain leaves or other portions of the plant above, and this is especially true of rice, the greatest care being necessary in watching their relative developments.

As soon as the germ root pushes out underneath the grain in search for food, a minute point is visible above ground, reaching up for light and air. This is the embryo stalk, and above it is the germ root. The plant is now in the proper stage for forcing, and the stretch water should be put on at once.

It sometimes happens, however, that the water, from tidal or other causes, is delayed, and the point, which is similar to that of barley or wheat, only sharper and more delicate, divides and assumes the "fork" stage, and the stretch that follows is from the fork instead of from the point. The contingency is undesirable, as the plant is thereby somewhat lessened in vitality.

The water is at first turned on deep, entirely covering the surface of the squares, and the young plant, drinking in the life-giving fluid, commences to rear its head aloft and reach up for light and air. The river water is seldom clean—always more or less tinged with mud—and the tender shoot battles manfully with its semi-transparent covering to bask in the comforting rays of the sun.

After the rice has become sufficiently stretched, or a few inches high—a period extending through from two to ten days—the water is slackened down to what is known as "slack water gauge," so as to show the tops of the plant and give it necessary air and sunshine. If the plant is longer than the water is deep, which is generally the case, it floats its upper leaves on the surface in long waving lines across the squares—a singularly attractive and beautiful picture.

It seldom happens, however, that the whole plantation is under the same treatment at the same time; for, with five or six hundred acres to sow, it is a difficult matter in early spring, with frequent interruptions from rains and bad weather, to seed down so large an acreage in time for utilizing any one spring tide for flowing. A large plantation will run five or six grain drills at once, and put in sometimes sixty-five or seventy acres daily; but even with as rapid work as this it is impossible to get all in contemporaneously. Consequently it is a common thing to see perhaps one fourth of the squares under the stretch water; another fourth under charge of the "gun squai," waiting for the tender point to shoot; another series under the sprout water, and the remainder in process of planting, all at once. This necessarily adds greater interest and diversity to the process and prospect.

Sometimes, too, the rice comes up mixed with "volunteer;" this is the product of the grain shaken out during the previous harvest and scattered broadcast over the land. This can generally be removed by the hoe, but where it is very thick it sometimes necessitates reploughing and seeding, thus throwing late a portion of the crop. This volunteer

rice is hardy and prolific, and externally similar to white rice, but the objection to it is that the berry is red, and greatly reduces the grade of rice with which it is mixed, besides totally unfitting it for seed. To destroy this obnoxious tare, the fields are sometimes thrown into dry crops for a year or two, or kept under water for a like time.

It will be remembered that each square is under separate control, and except where two or more are temporarily united by the check banks washing through, can be flowed and drained independently at the pleasure of the planter.

A walk over the banks of a plantation at this period is replete with interest; at every step the "huddlers," scurrying from under your feet and ducking into their holes, each one, as he disappears, waving aloft in defiance his disproportionate mantle. Yonder are small squads of negroes in twos and threes, dragging with long wooden rakes the floating trash and stubble blown by the wind in masses against the lee banks, and piling it on the pathways. Over their rattle the rattle of the grain drills is heard seeding down the few isolated squares. Here is the trunk-minder with his assistant hard at work repairing a leak. On the canal bank is the overseer in consultation with the planter on his daily visit to the fields, his little sail boat rocking at the wharf down by the quarter. Attention is called to a defective trunk or a dangerous bank; stretch water, to-morrow, must be turned on number six and number eight, and sprout water let off from seventeen and twenty-three. The long cord of the submerged thermometer is drawn in hand over head, its reading carefully taken, and the mean temperature of the water for the month in the overseer's handy note-book is compared with that of last year, and dependent operations deduced and determined. From the high and dry squares on the further side comes the casual pop of the musket, while flocks of daws and hungry crows circle overhead, awaiting their opportunity to settle down on the sprouting grain. Everything works in its appropriate groove and little is left to chance.

The stretch water is held at the slack gauge from twenty to forty days, when the "dry roots" and the leaves corresponding to it have put out. The amphibious and pampered plant has now had enough of its stimulating though strictly temperance beverage, and is ready for a period of "prohibition," or dry growth.

The development of the dry root is manifested to the skilled planter by its accompanying and corresponding leaves. To one ignorant of the subject the external appearance of the plant would indicate nothing at all, but the close student is familiar with every shoot and joint, and reads their story as from a printed page. Generally, however the leaf alone is not depended on, but for certainty's sake the plant itself is pulled up and examined and if the dry root has attained a length of from one half to three fourths of an inch, the plant is considered ready for the change.

The stretch water is now taken off gradually through a period of two to three days. As soon as the ground is dry—and these rice lands are so thoroughly drained that they dry much more quickly than one would suppose—the plow and the hoe commence their work, sometimes the one preceding, sometimes the other, but always at proper intervals.

(To be continued.)

TEA VERSUS QUININE.—The growers of cinchona in South America are so disgusted at the prices realised that many of them are foolishly rooting up highly productive trees, and planting tea shrubs in their place.—*H. and O. Mail.*

BECHE-DE-MER AND PEARLSHELL FISHERIES OF QUEENSLAND.

In a voluminous report relating to the beche-de-mer and pearlshell fisheries of Northern Queensland, compiled in association with his recent tour, extending over four months, Mr. W. Saville-Kent, Commissioner of Fisheries, gives much interesting and valuable information. In May last Mr. Kent was a passenger by H.M.S. "Rambler" for Torres Straits, and opportunity was taken of the time occupied by the officers of that vessel in making a systematic survey of the neighbourhood of the "Quetta" wreck, to investigate the marine fauna generally of that area. The valuable commercial variety of beche-de-mer known as red-fish was observed in some numbers on the exposed reefs contiguous to the Mid Brother Rocks. Black-lipped pearlshell was also found there, and on the reefs of Adolphus Island. Specimens of these were collected, taken alive to Thursday Island, and laid down on the experimental reserve. A considerable collection of the fish of this district was likewise made, which will, it is anticipated, be found on critical examination to contain many species not previously known to inhabit Queensland waters. On arriving at Thursday Island his attention was specially directed towards obtaining complete information concerning the beche-de-mer fisheries, and towards acquiring a personal acquaintance with all of the more important commercial representatives of that peculiar group of the invertebrate sub-kingdom variously distinguished by the popular titles of trepans, beche-de-mer, or sea-slugs. To accomplish this he proceeded to Tod, or Warrior Island, at the north extremity of the Great Barrier coral reef, and within forty miles of the New Guinea coast. This island is the headquarters of a considerable section of the Torres Straits beche-de-mer fishing fleet. The species of beche-de-mer collected and examined at Warrior Island were what are distinguished in the market by the titles of black-fish, red-fish, test-fish, prickly-fish, lolly-fish, and sand-fish. None of the literature accessible in Brisbane has enabled him to determine, with but one single exception, the technical identity of these commercial species, and it is a matter of some doubt as to whether they have as yet been scientifically described. The largest-sized commercial beche-de-mer observed in Queensland waters is the ordinary prickly-fish, or prickly-red, which, in its fully extended state, may measure 4ft. or more in length, with an accompanying diameter of 4in. or 5in.* Eighteen inches represents the mere ordinary extended length of black, red, and test fish. In all instances these organisms are capable of contracting to about one-half of their extended length, the holt under such conditions being relatively thicker. Mr. Kent describes the process by which beche-de-mer are prepared for the market, and the means by which the fishery is carried on. A good average take for a fishing station working with only four boats, carrying twenty to twenty-four men, is one ton of cured beche-de-mer per month. The collection of the beche-de-mer is accomplished in association with the low tides that obtain during the new and full phases of the moon, and eight or ten days are thus left in each lunar month which are not profitably utilized. The greater portion of the beche-de-mer is simply picked off the reefs when the water has receded, but the finest red and black fish, and the prickly-fish almost exclusively, are obtained by diving during the same low tides to a depth of two or three fathoms.

Respecting the bathymetrical or vertical distribution of commercial beche-de-mer, red, black, and prickly fish are reported to occur at a depth of four or five fathoms, and lolly-fish to have been observed by divers as deep down as eight or nine fathoms. The deep water examples of the red and black varieties, obtained by diving, are of the largest size, fetch a higher price, and are recognised by a distinct title in the market. The question has been discussed by certain of the boatowners as to whether beche-de-mer might be profitably collected with the aid of diving apparatus

after the manner of pearlshell, and will probably be put to a practical test. The southernmost point at which the beche-de-mer fisheries have so far been profitably worked is eastward from Mackay. Many large-sized species not yet turned to practical account, however, abound throughout the Australian littoral. One feature peculiar to a number of the non-commercial varieties is the habit they possess, when handled, of ejecting from the vent ropelike masses of a white cottony substance that on its first emission adheres with extreme tenacity to every object with which it comes in contact. It would appear possible that a useful ingredient for cement, having somewhat the property of caoutchouc, might be manufactured from this substance. The mere value of the total annual output closely corresponds with, but is somewhat in excess of, that of the oysters so extensively exported from the southern district of Queensland to the neighbouring colonies. China represents the market, which, with the exception of a few hundred weights, all the Australian beche-de-mer is consigned. Barrier fish enjoys a higher reputation and realises better prices than is obtained for the article derived from any other locality on the face of the globe. The most flourishing epoch of the Queensland beche-de-mer trade was experienced between the years 1881 and 1883, when the value of the total annual exports approximated or even exceeded £80,000. The most unpropitious point to the same industry was represented by the year 1887, when the total export value fell to £15,000. Since that date there has been an improving tendency, which is apparently still in progress, the licenses for boats taken out for the current year being in excess of last year's number. The returns in this direction show that sixtynine boats are now licensed from Port Kennedy, in Thursday Island, and twenty-seven from Cooktown. To these are to be added some half-a-dozen which have taken out licenses at Townsville, Cairns, and Ingham. This gives a total of over 100 craft engaged in the fishery. The current prices for beche-de-mer, as recently quoted in the Cooktown market, were as follows:—T at-fish, black and ordinary, £140 to £150; test-fish, white, £40; red-fish, ordinary and deep water, £100 to £110; red-fish, surf £80 to £90; black-fish, deep water, £110; black-fish or heavy and Caledonian, £80 to £90; lolly-fish £35; prickly-fish, or prickly-red, £30 to £40; sand-fish, £20 to £30. The prickly-fish or prickly-red, now realising from £30 to £40 per ton only, stood eight years ago at the head of the list, and readily sold at from £140 to £150 per ton. The heavy description in value arose from the circumstance that a consignment of this variety sent to China at about the time indicated had been boiled, previous to curing, in a copper vessel, with the result that a number of Chinese were poisoned. Poisonous properties were immediately attributed to this particular species of beche-de-mer, and it has never since recovered its original value in the market. A matter demanding serious attention with relation to the beche-de-mer fisheries of Northern Queensland is associated with the employment of native labourers. Of late years, and in the Torres Straits district more particularly, outrages committed by these labourers, in which the boatowners or their agents have been assaulted and lost their lives, or the boats with stores on board have been stolen, have become so frequent as to paralyse the industry to a very large extent. Not only have the originators of these outrages escaped punishment, but in many instances individuals known to have been associated with previous massacres and outrages have been re-empowered by other employers. Some essays at indiscriminate distribution of the native tribes, in which more of the innocent have suffered for the guilt, have been occasionally attempted; but until strict justice is administered, and the offending individuals only are made to pay the penalty of their actions, no amelioration of the existing miserable condition of the labour question can be anticipated. It has been pointed out to him that an official police station established on the Duval River at the point where it is crossed by the telegraph line would accomplish much towards the suppression of these outrages, as such station would not only be on the line of route

* Have sea slugs of such enormous size ever been found in Ceylon?—Ed. T. A.

traversed by the aboriginal natives, but would also be within a day's ride of either Capo Greuville on the east, and the Batavia River on the west, as the services of the police might be required. A more effectual remedy for the existing condition of affairs, and one that would conduce materially towards the establishment of the beche-de-mer industry on a more healthy and permanent basis, would be the appointment of a vigilant system of surveillance of the fisheries in association with the Government steamer stationed at Thursday Island. Mr. Kent advises that the inspector of fisheries, recently recommended for appointment with relation to the pearl and pearlshell fisheries of Torres Straits, should exercise similar functions with relation to that of the beche-de-mer, and, working in conjunction with the land and water police and Customs Department, be intrusted with full powers to supervise all transactions associated with the engagement and discharge of native labourers. Under such auspices a regular system of water patrol should be maintained, and all the beche-de-mer stations and fishing grounds be subject to visitation by the fisheries inspector at any and, if feasible, unexpected intervals. The recommendations made with reference to the appointment of a system of patrol of the beche-de-mer fishing grounds of Torres Straits will apply with considerable if not equal force to the fisheries of a like nature that are prosecuted along the Great Barrier and mainland coast south of Cape York Peninsula. An important matter connected with the employment of native labourers for the collection of beche-de-mer was brought under Mr. Kent's notice by a deputation of the leading boatowners and beche-de-mer merchants in Cooktown. In accordance with the existing regulation it is requisite that all native labourers engaged for this industry should be brought to the nearest Custom-house or shipping office to the place at which they were recruited for the purpose of registration. The compliance with this regulation frequently entails a very serious loss of time and money to the boatowners, from which they are anxious to be relieved. A remedy for the disadvantages under which the beche-de-mer industry is carried on, owing to the circumstances described, was suggested by the Cooktown deputation. This was that the registration of the native labourers engaged should be permitted at any of the lightships or lighthouse stations along the coast, and that the official in charge of them should be vested with the necessary powers to witness and sanction such registration. The concession sought being so reasonable, Mr. Kent has no hesitation in recommending it for favourable entertainment. The appointment of a well-qualified inspector of fisheries for the Cooktown district is greatly needed. The duties of such an appointment might be both appropriately and economically undertaken, with a suitable increment of emolument, in conjunction with the functions discharged by the present harbour-master. In intimate association with the beche-de-mer fishery may be mentioned the collection of tortoiseshell. The trade in this material is not of sufficient extent to constitute an independent industry, the greater portion of that which is exported being obtained by those engaged in the collection of beche-de-mer. The average annual value of this material that has been exported from Queensland within the past ten years has slightly exceeded £400. The highest figure, and one that indicates that the trade in tortoiseshell is increasing, was reached last year, when it amounted to as much as £1705. The prices of taint for Queensland tortoiseshell vary considerably, according to quality. The best and most valuable description is obtained from the true tortoiseshell turtle, which, if of superior texture, may realise from £1 to £1 5s. per pound. The thin and inferior descriptions of tortoiseshell produced by the edible turtle will not obtain a higher price than 4s. or 5s. per pound. The plan adopted for the capture of turtle by the natives of the Torres Straits Islands is remarkable. For this purpose they make use of the sucking fish, which in these waters attains to a length of 3ft. or 4ft. The fish, caught for turtle fishing, are kept alive in water in the bottom of the canoes, a thin line being secured to the tail and through its gill covers. When a turtle is seen in the water close to the canoe the sucking

fish is thrown out towards it, and immediately swims for and fastens itself to the reptile's carapace. If the turtle is a small one it may be drawn to the boat's side by the attached line, without the sucking fish letting go its hold; but if of large dimensions the native plunges overboard and easily secures it. There are other marine products besides that of tortoiseshell by which those engaged in the beche-de-mer fisheries might augment their incomes and turn to profitable account the spare-time intervening between the seasons most profitable for collecting the primary object of their attention. The edible turtle of the Pacific, if suitably prepared and dried, or otherwise preserved, would command a ready sale in the Chinese and other markets. The same may also be said of sharks' fins, which, at many stations on the Indian coast line, represent an extensive and highly valuable article of export. At one of the beche-de-mer curing stations in the Great Barrier district Mr. Seville Kent was informed that a corer had experimentally sent in some dried sharks' fins to Cooktown, which had readily realised among the Chinese residents a price of no less than 12s. per lb. This price represents £8 17s. 4d. per cwt; or, £177 per ton, and should encourage the establishment of a regular trade in the article. Sharks, and especially the smaller harmless species abound throughout the waters productive of beche-de-mer, and might, with a very trifling outlay, be made the object of a remunerative supplementary fishery. The livers of sharks and also of stingrays, which are exceedingly abundant in these same districts, yield a valuable oil, while their carcases, in combination with the waste products from the beche-de-mer, would make excellent manure, akin to guano and particularly rich in phosphates. Another marine product to which attention might be profitably turned by those engaged in the beche-de-mer industry is that of sponge. Examples of sponges, some few being of excellent quality, and others, though less fine in texture, having an undoubted commercial value, have been submitted to the commissioner as collected from a variety of stations along the North Queensland coast. A thoroughly systematic exploration of the waters in the neighbourhood of the beche-de-mer curing stations would, there is good reason to anticipate, result in the discovery of extensive beds of this valuable commercial article. A substance produced in great variety and abundance throughout the beche-de-mer fishing grounds, but which has hitherto received but scant attention, is that of coral. The form known as "precious coral" has not as yet been obtained from Australian waters, though the conditions favourable for its growth apparently exist throughout extensive areas. The descriptions of coral here referred to are those which enter so extensively into the constitution of coral reefs, and are probably nowhere in the world developed on so large a scale and in such a multiplicity of varieties as are to be found in the Great Barrier system of the Queensland coast. Small consignments of this coral are occasionally exported for ornamental uses, the bulk so far, however, rarely exceeding in one year a declared value of £40. The trade, nevertheless, is one that would appear to be capable of considerable development. Some dozen or so of the most readily accessible varieties, out of over 100 species that exist to choose from, represent all that have, so far, been turned to commercial account. These, nevertheless, when well prepared, have attained good prices; 30s. to 40s. per cwt, each case containing perhaps half a dozen specimens, and weighing, collectively, less than 1½wt, being the ordinary charge. There is no doubt that well-selected collectors of the Barrier Reef and Torres Straits corals, such as could be selected and prepared with the greatest facility at any of the beche-de-mer curing stations, would command a ready sale as articles of intrinsic beauty at suitable depots in all of the larger Australian cities; the museums throughout the world would gladly utilise the opportunity of securing type collections of the innumerable corals of the Torres Straits and Great Barrier regions. A remarkable species that is not unfrequently obtained by the pearlshell divers in Torres Straits and throughout in the Barrier region is the black coral. This coral possesses a high commercial value in the Indian marke

the supplies hitherto having been chiefly derived from the vicinity of Jeddah, in the Red Sea. The produce of the Jeddah fishery has greatly diminished within the last few years, and the discovery of any new sources of supply would be gladly welcomed. There is, Mr. Kent considers, every element in favour of the development of a profitable black coral fishery in North Queensland waters.

Mr. Kent reports the complete success of the experiments conducted last year at Thursday Island in the direction of transporting and artificially cultivating the mother-of-pearl shell. The specimens brought in from the outer fishing grounds and laid down on a selected reserve on Vivian Point, have thriven to a remarkable degree, and had added, on an average another inch to the diameter of their shells since their transportation to the reserve eight months previously. Attempts have already been made at several of the shelling stations to bring pearlshell in alive from the fishing grounds and to lay it down in the vicinity of the stations. These experiments have been attended with partial success, but are not likely to be prosecuted in a thoroughly systematic manner until the bill recently drafted is passed which will secure to those engaged in the trade the power of taking up portions of reefs and fringes for pearlshell culture, and afford them legal protection for the shell laid down. I found on my arrival at Thursday Island that the opinion among those engaged in the pearl-shelling industry in favour of legislation to restrict the limit of the size of the shell taken by the divers had greatly increased. At a meeting of the trade representing seventy-three boats, held during my visit, a resolution was unanimously passed advocating the appointment of a defined limit. Since the submission of my last year's report, the commissioner has been further impressed with the conviction that pearl and pearlshell fisheries might be profitably worked or developed throughout the Southern part of the Northern moiety of the Queensland seaboard. Black-lipped shell, of large size, having a market value of £50 or £60 per ton, from which excellent pearls may be obtained, have been collected as far south as Moreton Bay. Confidence in this anticipation is shared to such an extent by one of the leading pioneers of the Torres Straits and West Australian pearlshelling industries that he is making arrangements to fully test the pearl and pearlshell producing properties of the Southern coastline, and to establish thereon stations for the purpose of pearlshell cultivation so soon as the Act is passed that will accord the necessary protection and facilities for the development of this new industry.

—*Queenslander.*

THE NEW CHLOROFORM DISCOVERY.

There is no reason, on the face of it, for doubting the reported discovery by M. Pietet of an improved method of manufacturing chloroform. The gentleman is a distinguished Geneva savant, who long ago won his scientific spurs by his well-known researches, carried out in 1877 simultaneously with those of M. Cailliet, on the condensation of oxygen, hydrogen, and other gases. Those researches were of a very important character and constituted a real step in our knowledge of gaseous bodies. There had previously been a distinction made between "permanent" and "non-permanent" gases—that is to say, between those which could be converted into liquids and those which could not. But MM. Cailliet and Pietet showed that no such distinction really existed, and that all gases could be reduced to the liquid, and even to the solid form. The method by which this is effected consists essentially in a combination of very high pressure with great cold, and apparently M. Pietet has made his new discovery by pursuing a similar line of investigation. He reduces chloroform to a very low temperature and is then able to separate the impurities.

With regard to the practical value of this achievement it would be rash to speak with any certainty.

The idea is that the new chloroform will be much safer to administer than the old; but two things may be said on this head. It is quite true that at present it is difficult—perhaps impossible—to obtain the drug absolutely pure, and the variability of its composition is shown by the different specific gravities adopted as the standard in the pharmacopœias of different countries. But, in the first place, it has yet to be proved that chloroform, as manufactured in England—or rather, in Scotland—since the days of Simpson, is dangerous when properly administered. All the evidence, regarded with an unprejudiced mind, points very strongly to the conclusion that the danger is not in the drug—excepting in so far as every powerful drug is dangerous—but in the hand which administers it. And in the second place it has yet to be proved that the danger, if it exists, is due to impurities. If, as is alleged, chloroform has never been obtained pure, how on earth can it be known that the pure, which has never yet existed for practical purposes, is safer than the impure? It may be precisely the other way. We have recently had a lesson in this direction which should not be forgotten. We have learned that in this case of spirits chemical purity by no means implies wholesomeness. It has been shown that the "beautifully pure" product of the patent still gives you a violent headache, while the old-fashioned pot-still stuff, reeking with fusel-oil and other supposed abominations, is perfectly innocuous. The human interior, for reasons of its own, often takes a different view of these matters from that of the chemist; and it may be so in the present instance. At any rate, that has all got to be found out, and it would be foolish to jump to the conclusion that the new and improved chloroform—supposing it exists—will necessarily be a perfectly safe thing to administer just because the advertisements say so. Its real value can only be ascertained by prolonged trial. Of course the medical profession knows that, and will use the novelty with all due care. But unfortunately, as we know by experience, the public nowadays does not wait for an authoritative verdict, but flings itself upon everything new if sufficiently advertised, and patients are quite likely to insist on being anesthetized by M. Pietet's chloroform before anything is known about it.

The rumour that M. Pietet is negotiating with Gorman manufacturers for the establishment of a monopoly should also be received with caution. Such a proceeding would certainly raise a tremendous storm in France; though to be sure, he may care nothing for that. Still it is unlikely; and surely things have not come to such a pass that every scientific discoverer must sell his brains to speculators in Berlin.—*St. James's Budget.*

BURMA RUBY MINES CO.

LONDON, July 10th.

The report of the meeting of the Burma Ruby Mines Company which is enclosed with this (see page 175) must, in view of the kindred pursuits which several companies have been endeavouring to follow in Ceylon, be interesting reading to you. The Company does not seem to have met with any larger measure of success as yet than that which has attended the efforts made in Ceylon. Everything is reported, promises fairly, but so did every thing when the undertaking in Ceylon was embarked upon. There are several matters which were touched upon by the Chairman, Sir Lepel H. Griffin, which must seem mysterious to general readers. Why, for instance, is it to be only anticipated that good rubies may be found? It had always been our belief that the Burma Ruby Mines

had already given ample proof that stones of such a quality were abundant in Burma, and yet we are told that "they had not yet obtained stones of the quantity and quality which they hoped to get." This is pretty much the same thing as has caused so many similar enterprises in Ceylon to be abandoned.

Then, again, we have the statement as to the apprehension that the natives employed on the works obtained and secreted many, if not most of the really valuable stones which had been unearthed. This, as you know, was one of the chief obstacles foreseen as likely to militate against success in Ceylon which were stated to me by Mr. Streeter on the occasion of my interviewing him upon the subject when the question of systematic gemming in Ceylon was first mooted. As yet it is evident that the work which has been done during the several years since the Company commenced its operations at the mines has been almost entirely confined to preparation. It is very certain that, had this case of "hope deferred" been realized when the prospectus of the Company was issued, we should not have witnessed that excited rush after its shares which created so much astonishment at the time.

Although, of course, the Chairman has said the best that could be said for the prospect before his shareholders, we fear the latter are scarcely likely to have their hopes strongly revived by anything that fell from him. It is not to be doubted at all events that they will yet have to pay very heavily before they can obtain any appreciable results to their investments, and the fact will doubtless go far towards consoling those other speculators who have ventured their funds in a similar enterprise in Ceylon. "The misfortunes of our friends" are said currently to be always a source of concealed gratification to ourselves.—London Cor.

HOW OTHERS SEE CEYLON PLANTERS will be gathered from the following letter:—

TO THE EDITOR, "INDIAN PLANTERS' GAZETTE."

Sir,—Having been on a visit to Ceylon and seen a few of the Ceylon tea estates, I send you my impressions on the subject as likely to interest your readers.

What has struck me chiefly is the vast amount of push and energy among the planters, and the vast area under tea point to a plentiful supply of capital.

Another point is institution of large central factories, where the leaf is either purchased from neighbouring gardens or manufactured for them.

Manufacturing charges, including all expenses of packing, and carriage *f. o. b.*, Colombo, are about 5 cents or 1d per lb. The labour here is Tamil, or South of India; this labour should answer for the Doonah, Assam, and Cachar, and on account of the cheapness of rice in those provinces, labour should be obtained at present rates, Rs per month, and recruiting expenses should not cost more than Rs 15 per head to the different gardens.

Labour is paid for here at the rate of six annas per day for men, and four annas for women. Price of rice Rs 6 per maund (no recruiting expenses); yet in spite of these enormous wages, Ceylon planters put down their tea *f. o. b.* Colombo from 25 cents (four annas) to 32 cents (five annas) per lb. respectively, low and hill country.

There are 230,000 acres under tea in Ceylon, the lowcountry yielding 500 to 1,000 lb. tea per acre, and the hill country (at an elevation of 5,000 to 6,000 feet) 300 lb. tea per acre, the average of the whole area under tea in Ceylon will be about 400 to 500 lb. per acre.

In machinery they are not behind hand, in fact ahead of India in drying machinery. I will note first the "Brittania," Jackson's latest invention, said to beat the Victoria, though each has its own merits.

It costs about £300 and turns out 240 to 300 lb. dry tea per hour, and the tea takes to dry 30 minutes for each tray, and dries at a temperature of 200 deg. (though this could easily be increased to 240 deg.), the Ceylon method being a vast quantity of low heated desiccated air.

It occupies a space of 30 feet x 10 feet, is a love machine, turns out good tea, and is automatic, being a series of trays on an endless chain, and self-dig churning.

Mr. Jackson will be over in India before the end of the year as soon as his roller injunction case is decided.

To those who prefer smaller machines there is the Brown's Patent Desiccator in two sizes, turning out respectively 80 to 120 lb. tea per hour. This is a combination of up-draft and down-draft, and dries tea at a temperature of 230 deg., or any other heat desirable, and cost for the larger size about Rs 1,500 in Ceylon.

Both Jackson's "Brittania" and Brown's "Desiccator" are machines new to India, and Indian planters should have a look at them, as they are well worth attention and highly spoken of.

The sifters are Walker's and Brown and Rae's rolled leaf breaker and sifter, and dry tea sifters by the same manufacturers which do not grey the tea.

Unless Indian planters wake up, Ceylon will push them into the corner, and before another three years the export from Ceylon will be 92 millions, and the value of tea due to over production will fall to 8s. per lb.

This is the blight (over production) which both India and Ceylon will have to face; the tea bushes in Ceylon are healthy and not yet blighted, and there is no reason why tea should not last here for 25 years as in India. I know Indian planters will say "their lands will grow tea for a century," overlooking the fact of the enormous quantity of old tea land abandoned, and new tea planted to enable old estates to hold their own.

Ceylon estates are kept clear of weeds, and bungalow managers (however clever they may be) are at a discount, not waited at any price.

A WANDERER.

THE PRICE OF QUININE.

(COMMUNICATED.)

The industry of Cinchona cultivation, the source of quinine, has reached a critical stage in its development and there are some facts connected with it which are of public interest, and which should be more generally known.

In 1860 the Cinchona tree was introduced into India by the Government, who employed Mr. Clements B. Markham to bring plants from South America which country was at that time the sole source of supply of the so-called Peruvian bark. Plantations were established on the Neigherry Hills in the Madras Presidency, and at Hagkela in Ceylon; and in 1872 the first crop of bark was obtained. The cultivation of the tree spread to the Himalayas, Java, and other places, with the result that the importation of bark from the East into this country has averaged of late years about 14 million pounds, and it is estimated that the total exports from the East for the twelve months ending the 1st July next will amount to not less than 15 million pounds. If to this we add the exports from South America, which are, however, insignificant, we have a total of 16½ million pounds of bark (equivalent to about 8 million ounces of quinine), and representing one year's production for the use of the world.

The object which the Government of India had in view was the provision of an abundant and cheap supply of the febrifuge for the use of hospitals and troops in India, as well as for the people generally, in a country where fevers of a malarious type are exceedingly prevalent, a source of numerous secondary diseases and great mortality. It was also recognised that an increased supply of this unique and valuable drug could not fail to be a benefit to the world at large.

The effect of the successful cultivation of the Cinchona tree in the East on the wholesale prices of both bark and its derivative, sulphate of quinine, has been truly remarkable, both in this country and the Continent. Bark, which in 1880 realised seven shillings per pound, can at this date be purchased in London for fourpence-halfpenny per pound, and quinine, which then was sold for twelve shillings per ounce, can now be obtained from the most noted manufacturer for one shilling and fivepence per ounce, while the German article is priced at from tenpence to one shilling per ounce.

Taking the present normal consumption of the world at seven million ounces of quinine per annum—a figure which is accepted by the best authorities—the fall since 1880 in the value of the drug annually consumed is not less than 3½ millions sterling at wholesale prices.

The trade in bark with South America has been practically destroyed, as it is no longer profitable to export it, and the wholesale prices obtainable in European markets for bark are so discouraging to planters, and the glut is so great, that the trees are being largely uprooted and replaced with tea shrubs.

The estimated number of Cinchona trees in Ceylon was, in 1882, 90 millions; in 1886, 70 millions; in 1888, 35 millions; and in 1890, 19 millions.

This glut and these low wholesale prices are not due to a supply in excess of the needs of the world, but mainly to the extraordinary fact that the retailers of the drug have generally declined to follow the wholesale market, and have practically succeeded, so far as the great mass of the public is concerned, in maintaining retail prices at an altogether artificial, and to many a prohibitory level. The price commonly put upon Howard's Quinine by retail druggists in various parts of London varies from 6s. to 8s. per ounce, when delivered in the condition in which it is received from the manufacturer; that is to say, without being compounded. In country districts it is often far more expensive, and to a great extent beyond the reach of the poor.

It is remarkable that these exorbitant prices are maintained notwithstanding the fact that a number of the co-operative stores retail quinine at present at 2s. per ounce, even then making a gross profit of over 40 per cent. on the wholesale price of 1s. 5d. per ounce.

Present circumstances lend additional importance to these facts from the point of view of the public interest. Quinine is a drug which is almost universally prescribed by medical men at some stage or other of every attack of influenza, and there is very good ground for considering it to be one of the very best prophylactics which can be taken during the prevalence of the epidemic. It is, therefore, the more desirable that the public should obtain the full benefit of the cheapness of quinine in the wholesale market. This end can only be attained by combined action on the part of the planters and importers of Cinchona bark, as well as manufacturers of quinine, with a view to the removal of any restrictions which may exist on the retail sale of the drug in whatever form it may be required.

The Government of Madras, in furtherance of the policy which originally led to the creation of their plantations of cinchona in India, have recently directed their revenue officers to keep a small stock of quinine for sale to the people, in order that the value of the drug may become known to them, and that a demand for it may be encouraged. This is a step entirely in the right direction. There are millions of people in Asia who have never heard of quinine, and who are totally unacquainted with its properties. Those however, who from contact with Europeans or otherwise have had experience of it, value it most highly. Mr. Colquhoun, the well-known traveller, in his work "Across Chryse," writes: "Quinine is the best present any traveller in Yunnan can carry," and mentions also that it is considered to be a cure for the craving which those accustomed to opium-smoking suffer from.

It would be unfortunate if the existing want of harmony between the wholesale and the retail machinery of distribution which has been described should lead to a serious falling off in the cultivation of cin-

chona, and consequent scarcity of a valuable remedy, the use of which might obviously be extended in many countries with benefit to the inhabitants.—*Economist*,

BARK AND DRUG REPORT.

(From the *Chemist and Druggist*.)

LONDON, July 9th.

ANNATTO.—Two hundred and fourteen bags of seed were offered at the sales today, but only 27 bags bright, and eleven Ceylon sold at 1½d, while the rest, fair to fine bright, is held at 1½d to 2½d, a bid of 2d for the best having been refused.

CINNAMON.—Thirty-eight bales Ceylon partly sold at 7d to 9d.

EUCALYPTUS-LEAVES.—A parcel of very ordinary and old E. Globulus leaves could not find a purchaser.

ESSENTIAL OILS.—Citronella Oils: There was an attempt to sell 20 cases by one broker. He was prepared to take ½d, but could not get it. Nutmeg Oil: A new parcel of this oil sold at 3d. There were also offers of bay, bergamot, cinnamon, cinnamon-leaf, and Japanese peppermint oil, but none sold.

NEW GUINEA EXPLORERS.

Lying in the harbour of Singapore at the present moment is a small schooner whose only outward characteristic is that of a stump foremast and couple of deck houses above the ordinary size. Yet the "Envy" is no ordinary craft nor the Captain of her to be summarily dismissed from notice. Since the year 1874 has Captain Strachan devoted the greater part of his time to New Guinea, and of that little explored mass of land he knows probably more than any other man living. Part of the south-east is named after him and his explorations have extended for miles and miles of river. They will be found written in an interesting book compiled by the Captain while at home in 1888, which is better known down in Australia than in these parts. As the leader of the "Age" expedition, a profuse writer of New Guinea and other matters Captain Strachan has made for himself a name among the Australians as a sturdy independent man, with unbounded determination to do thoroughly whatever he turns his hand to. Like most independent men, he has made enemies as well as friends, and many and bitter things have been said against the explorer, but he has triumphantly vindicated himself from calumnies and is as ready as ever to attack what he deems the wrong.

The "Envy" coasts round New Guinea and the adjacent islands, through uncharted seas and in the midst of the treacherous natives, of whom her Captain says, although he has succeeded in establishing the most cordial relations with them, that they are emphatically not to be trusted. It is not to be wondered at, therefore that the armament of the vessel is a good one, including a number of swivel guns mounted on the bulwarks. The "Envy" is but a small boat, but she is eminently a serviceable craft and her Captain has every confidence in her. She has just lately come up from New Guinea and will stay here a short time for repairs, after which the Captain will resume his wanderings, going in the next instance to Melbourne "to interview the Victorian Government in connection with a scheme for the advancement of the interests of the Commonwealth of Australia in Polynesia."

Mrs. Strachan, who is accompanying her husband, takes a great delight in natural history and has had experiences that fall to the lot of few ladies. The Brisbane *Boomerang*, under the heading "A Queen of the Sea" tells the kind of woman she is:—"Of medium height, a slight but graceful figure, Mrs. Strachan possesses in a marked degree the oval face and regular features of the daughters of Tasmania, her native land, in which her progenitors yet bear a well-known name. Well educated, she is by no means a naturalist, conchologist, and linguist, is now preparing for publication a book of her travels and adventures, and what has more than once stood her in good stead, almost as unerring in aim with rifle and revolver as a crack shot among the backwoodsmen of America. As is well known in marine, mercantile, and other circles, Captain

Strachan has for some years past been opening up a trade in Dutch New Guinea, the Malay Archipelago, and other places, even now a *terra incognita* for other British traders than himself, with results that promise great things in the near future for the commerce of this colony. In the taut little brig 'Eury,' 90 tons burden, Mrs. Strachan was on the last three voyages her husband's helpmate and companion being in fact the only other 'white man' on board. A good sailor, a fair navigator, able to take her trick at the wheel, she was equal to any position, from supereargo to chief mate, and it was while acting in the latter capacity that she proved herself a brave woman, full of resources and equal to any emergency. On his last voyage Captain Strachan had for his crew a number of kanakas, a Malay as chief mate, and Mrs. Strachan, who was entered on the ship's papers as supereargo. After leaving Townsville the Malay began to show he was anything but a desirable member of the ship's crew. He became insolent and insubordinate, and, to add to those odious of demeanor, Captain Strachan heard at Somerset, Mr. Jardine's station in Albany Pass, that his first officer was anything but what he had represented himself to be on shipping. At Thursday Island he bore the reputation of a sullen, morose fellow, who, at certain phases of the moon, was given to enter upon an indiscriminate carving of his coloured compatriots, and a dark cloud hung over him in connection with the violent death of one of his countrymen at Townsville. As the voyage proceeded matters with the mate became worse, until one day they reached a crisis, and Captain Strachan calling the crew aft disgraced the Malay, and duly installed Mrs. Strachan into the position of next in command to himself, the crew promising their allegiance to the new order of affairs. But the Malay at once commenced to attempt either to cajole or intimidate the crew into insubordination and revolt, and it became necessary to place him under arrest in irons. So the voyage proceeded. Island after island was visited and the vessel's hold began gradually to fill with nutmegs and mace, deer's horns and *beche-de-mer*, pearl-shell and valuable timber of beautiful grain; her decks became alive with rare birds and rarer beasts; and the ship everywhere showed signs of having cut red upon a prosperous and profitable trade. But on all sides the captain heard tales of troublesome times. Here a party of Arah traders had been murdered in cold blood while partaking of the hospitality of their treacherous hosts; there came warnings of plots to cut off and seize the ship; everywhere the necessity for precaution existed, and the strain of anxiety became trying and severe, in the morning the vessel would be crowded with savages greedy for trade—more greedy for murder, spoliation and the subsequent cannibal feast—with an armed guard of kanakas at the hatchways, the captain and his wife, both with each hand on the butt end of their revolvers, carried on the perilous trade, and the holds of the ship each week reached nearer the desired complement until at last the trading was over, the hatches battened down, and the vessel's head pointed homeward. Then, as the ship slowly sailed past or lay becalmed at the different islands, constant watch had to be kept upon the numerous canoes, full of armed men which glided as noiselessly through the dark waters of the night, as does a snake through the grass. Through these anxious times Mrs. Strachan, the chief mate of the 'Eury,' was ever at her post. Her eye ever quick to see approaching danger—her hand ever ready to keep up the constant fusillade of cannon or musketry or to send heavenward the fiery rocket to scare away their cowardly foes. At length the ship reached more open waters and the heavy strain was removed; but with the relaxation came even more trying times for the brave woman who had passed through so much with dauntless courage. Upon Captain Strachan the constant anxiety for the safety of his wife and his ship, the incessant toil and exposure left their mark. Fight as he would against it, an enervating lassitude crept over him till at last he lay helpless in his cabin. The cook also fell ill, and upon Mrs. Strachan devolved the task of navigating the 'Eury' through a da-

charted sea and acting as nurse to the invalida besides provisioning and keeping up the spirits of the remainder of the crew. Nobly she did her duty, but though her courage had been freely tried it had yet to undergo a more severe ordeal. Standing at the wheel one evening she saw the sun go down upon an angry sea and rising storm and all the unknown perils of the night to be confronted without her husband's aid. Hastily descending into the cabin she tried to arouse him sufficiently to obtain a few necessary instructions for her guidance during the storm then so fast approaching. But she tried in vain. As she lay to arouse the dead as one so prostrate and unconscious as was her husband. The exhaustion following upon his long sustained exertions claimed him as its victim and Mrs. Strachan was cast upon her own resources. Soon the wind shrieked through the rigging with hurricane force, and the vessel rose and fell upon the storm-lashed waters like a blind man pushed on by an irresistible force to an unknown destination. With stern set face and strained eyes Mrs. Strachan kept her post at the wheel, her voice, rising high above that of the storm king, ever and anon directing the labours of the crew. Then for a moment came a lull; the lightning's glare and the thunder's roar ceased—and then with redoubled force, the hurricane burst upon the vessel and all seemed lost. Carcering over the tops of the masts met as though in a last embrace with the crests of the angry waves; the sails burst asunder with a noise as of the cannon's roar, and their shreds were scattered far and wide. Suddenly the scene was illuminated by an electric glare of more than ordinary duration, and by its lurid light Mrs. Strachan saw the mutinous Malay loosing with his hands or slashing with his knife every piece of rope or rigging with which he came in contact. Beckoning one of the kanaka crew to the wheel, she made her way towards the desperado mutineer, and when once again the darkness of the night was dispersed by the lightning's flash the woman and one madman were seen confronting each other. With upraised knife and glaring eye, she with levelled revolver and undaunted look. The conflict was but momentary. He like a boston cur crept back to his lair; she like the heroine she was, went steadily back to the wheel, and when morning dawned the ship was safe, and a few days after Captain Strachan was enabled to assume command and bring his vessel safely into port. As showing the sort of man Mrs. Strachan had to deal with, it may be stated that although the Malay was afterwards re-ironed he was able to throw them at the feet of the police officer who came aboard at Brisbane to arrest him and say, in so many words, no iron could hold him. In a few days the 'Eury' will once again steer her course to the scenes of her former perils and once again Mrs. Strachan will form portion of her crew. There has arisen a doubt in the minds of those in authority as to whether her husband can ship her, as he wishes to do, as his chief officer, but in whatever capacity she 'signs articles' Mrs. Strachan's many friends will wish her a prosperous pilgrimage among the isles of savagery and spices and a safe and speedy "return home."—*S. F. Press*, July 15th.

TASMANIAN APPLES.—During the month ending June 30th of the present year there were imported into the United Kingdom no less than 64,024 bushels of apples, of the value at £37,854, as against 8,798 bushels, valued at £6,237 in the corresponding month of 1890. This remarkable increase is entirely due to the large shipments received from Tasmania and New Zealand, which, arriving at a time when the supplies from America are almost over, have met with an eager demand at remunerative rates. So satisfied are the Australasian growers with the results achieved that preparations are being made for still larger supplies to be placed upon the English markets during the next season.—*Times Weekly Edition*, July 10th.

THE APPLICATION OF MANURES.

Mr. Pringle, on this occasion (see his paper below), deals with a practical subject of great interest to planters; and although his remarks apply primarily to coffee culture, the principles enunciated are equally applicable to the tea planters' pursuit. Mr. Pringle seems to have fixed on 4 cwt. (one-fifth of a ton) of artificial manure as the appropriate quantity for an acre (calculated to operate, we suppose, for the orthodox period of three years); but he recommends that the artificial manure should be "diluted" by a larger quantity of cattle manure, or with at least its own bulk of burnt clay. The merits of this latter substance, especially its power of absorbing nitrogen, have been long acknowledged; and we suppose the reason why it is not more largely used is the expense of preparing it, especially where fuel is scarce. The necessary attention to a mass of brushwood and logs, which, under a covering of lumps of earth, must be kept smouldering for three weeks or a month, must in many cases act as a deterrent. But where clay is prepared as recommended and applied, especially to stiff, wet soils, the results will well repay all the trouble and expense. In the early days of our connection with the *Observer*, "Burnt Clay" was the familiar signature to a series of letters by old Mr. Hawke, who came to Ceylon from Mauritius with the Chermonts and others in "the forties." As an absorbent of ammoniacal matter in horse stables, cattle sheds, pigsties and poultry houses, its value can scarcely be over-rated. Mr. Pringle advises manuring only at the termination of the monsoon rains; he denounces mammoth digging; recommends the use of the alvanga instead; and advises the surface and broadcast application of manure after a slight forking, which will do the smallest possible injury to the feeding rootlets. We suppose no one thinks of applying manure in the heavy and almost constant rains of the monsoons; but we suspect that, in view of the generally raininess of our climate and the steepness of our gradients, few will venture to exchange the system of shallow trenches for the broadcast surface process recommended by Mr. Pringle. Readers who are planters and who manure their fields will, however, judge for themselves. The kinds of artificial manure which Mr. Pringle favours have been already mentioned, but there are few if any better than the old Ceylon favourites: finely ground bones and white castor cake. If some fish can be added so much the better, especially if "dilution" with burnt clay is resorted to.

APPLICATION OF MANURES.

By WILLIAM PRINGLE, M. S. C. I.,

LATE AGRICULTURAL CHEMIST TO MESSRS. MATHESON & CO. IN COORO.

(Under special arrangement for publication in the "Ceylon Observer" and "Tropical Agriculturist.")^e

Having selected the manure or manures intended for use on the estate, the question is how to apply it so that the maximum results may be produced at the minimum cost.

First to ensure equal distribution it is necessary to dilute such concentrated manures as bones, fish, hindcay* and other artificial manures with cattle manure or burnt earth. If cattle manure is procurable it may be used at the rate of two or more bandy loads mixed

with the artificials, per acre. Where there is not sufficient, burnt earth will be found most useful.

The following analysis shows the change produced by burning a soil:—

	Parts per 100.	
	A	B
Original Matter and Combined Water*	7.572	.623
Oxides of Iron and Alumina	10.369	14.345
Lime	.253	.499
Magnesia	.161	.196
Potash	.070	.389
Soda	.026	.096
Phosphoric Acid	.159	.289
Sulphuric Acid	.023	.069
Insoluble Silicates (sand &c.)	81.367	83.494
	100.000	100.000
* Containing nitrogen	.180	.005

The burning has practically destroyed all the organic matter and nitrogen. (it is rather over burnt), but has rendered some of the insoluble silicates soluble; the increase of potash as shown by analysis B is partly due to that and partly to the wood used in burning. At least 1 cubic yard of burnt earth or 1 ton of cattle manure should be mixed with every 4 cwt. of artificials (the quantity of bones &c. necessary for one acre).

To prepare the burnt earth select good yellow clay, or peaty swamp soil, cut it into six to nine inch cubic clods, dry them in the sun. About six cubic yards should be out for every ton of manure that is to be mixed.

The clods when dry are built up into a heap with layers of brushwood (coffee prunings and shade loppings will do); a little heavier wood should be used at the bottom to start the fires.

It is a mistake to use too much wood, or to allow the heap to burn too rapidly; instead of actually burning, it should smoulder gently. A heap ten yards long by two high and five broad should take about three weeks or a month to burn.

The earth should not be red when burnt, but just in part beginning to turn red; if of a nice warm brown color when finished it is excellent. If the fires are going too fast plaster the outside with mud. It is rather good than otherwise to have a fair percentage of charcoal left in the heap, especially if the manure is intended for poor sandy soils. When the heap has cooled down break up all the clods and pass them through a screen with four meshes per linear inch; better results will be got if a 16 mesh screen is used, but the cost of pulverizing will be considerably increased. It is now ready for mixing with the manure and the following plan will generally be found best.

Upon a clean dry floor or herbage spread a layer of two inches of the prepared earth (or dry pulverized cattle manure); upon it spread ½ an inch of bone meal or other manure or manures, over this burnt earth, and so on earth, manure, earth, finishing with the latter. When the heap is about 12 to 15 inches thick, turn the whole over; first from one end then from the other, then from one side, then from the other; finally simultaneously from the four corners throw the stuff up into a heap in the centre, and carefully turn it over twice. Then pass it through the screen, and again turn it over. This is necessary to insure an equal proportion of manure throughout the mass.

It is now ready to cart out to pits, which should be cut one for every five acres; a convenient size is 4½ feet deep, 6 feet wide and 7½ feet long.

When these are filled with the mixed manure they should be covered with about a foot of earth and thatched over, a gutter being cut round to run off the monsoon rain.

If raw bones are used it is sometimes advisable to sprinkle water over the manure as it is put into the pit to facilitate fermentation; just damp it. Having the manures in pits obviates the necessity for cartage when the roads are soft. The manure can be prepared and carted out in the dry weather.

* No doubt the local name for some oil-cake, —ED. T. A.

It should be got out as soon as the heavy monsoon rain is past as possible. If put out just after crop it is exposed for months to a blistering sun, followed by 20 to 25 inches of rain in June and July. With a monsoon of 65 inches over 6,000 tons of water fall on an acre of land, sufficient, if all fell at once, to submerge the whole district to a depth of 5 ft. 6 inches. Of this enormous quantity of water about 1,000 to 2,000 tons fall in June and 1,500 to 2,000 in July. During these two months the rain is generally so continuous that only a very small proportion is evaporated, the temperature only varying from 60 deg. to 76 deg. Fb. the barometer almost steady at 28.5 inches, and only about 3 deg. between the wet and dry bulb thermometers. The bulk of the rain must therefore pass off by surface or subsoil drainage. In either case this heavy downpour will wash all the soluble salts down below the feeder roots or carry them off with the surface wash; at any rate a very large loss must occur, and this is probably the reason why such a small percentage of potash is found in tropical soils. The following experiment proves that such is the case:—

20 lb. cattle manure or rather pure dry grain-fed cattle dung was placed in a basket, which was buried in the ground up to the rim, in such a way that it was not subject to surface wash, but it was as nearly as possible under the same conditions as the surrounding soil.

To preserve the basket it was carefully washed with a strong solution of arsenite of copper and then tarred.

It was left exposed for four months, namely, May, June, July, and August.

The dung taken out dried and weighed was found to have lost 22.5 per cent in weight and deteriorated in quality over 50 per cent.

The following analyses will help to make this clear:—

Pure Dung.

	Before Exposure.	After.
	Parts per 100	
(1) Organic Matter	85.86	62.51
Lime	1.87	1.49
Alkaline Salts	1.31	.48
Phosphoric Acid	.90	.83
Iron and Alumina	1.08	1.30
Insoluble Matter	28.60	33.03
Undetermined	.38	.27
	100.00	100.00

(1) Containing Nitrogen .517 .212

Should these figures fail to convince anyone let him just look at the rush of water over and off the surface of a piece of flat land such as a tennis court, or a road, when a thunderstorm of an inch or more rain falls in an hour, or when there is a pucca burst of the monsoon, registering 4 to 6 inches in 24 hours, and I think he will agree with me that it is necessary to supply the tree with easily assimilable food as soon as possible after the heavy rains are past, to compensate for the monsoon loss.

I cannot too strongly urge the planters of Coorg to put out their manures during the first break at the end of July or in August. All other works should be subordinated to this, even supplying. It is the crop that pays for this and every other work. If labor is obtained there is plenty of time for supplying, but the time at which manure can be applied to obtain maximum results at the minimum cost is very limited.

The coffee tree is a surface feeder; and unless the land has been deeply cultivated from the beginning and is of loose and friable character few feeder roots are found below 6 inches in comparison with the number above that depth. This

is due to the necessity of surface, broadcast manuring, by which I mean that in good coffee free from blanks, that the manure should be evenly scattered over the surface up to within about a foot of the stem, and lightly forked in. An account of an interesting experiment first devised by Nobbe will I hope satisfy you of the necessity for distributing the manure evenly round the tree.

Any planter can make the experiment and so satisfy himself of the correctness of the following statements. Take a good-sized tub say 2 feet in diameter by 2 ft.

deep, bend a piece of tin (an old kero-sine oil tin will do) at an angle of 90 deg. and place it on end in the tub fitting the edges to the tub sides, so that it is possible to fill the tub with well washed sand without encroaching on the enclosed fourth. Bore some holes in the bottom of the tub, fill in for three inches with clean washed pebbles or broken quartz, pieces $\frac{1}{2}$ to 1 inch will do, fix the tin in position, fill with clean well washed sand outside the tin. And in the fourth enclosed fill with first-class soil; arranging in it three vertical tubes place about three inches or so apart and equidistant from the centre.

The tubes should not be over two inches in diameter; they may be of tin, copper, glass or any other material; stiff paper rolled round a rod and glued so as to form a tube will do. Cleanpat the soil gently round the tubes, and fill one with bones, one with fish, and one with cattle manure, all in fine powder. Now withdraw the tubes, leaving the columns of manures standing in the soil, and then withdraw the angle tin, leaving the soil and sand in contact; if the work is well and carefully done the manure will not be mixed with the soil, nor the soil with the sand.

Having prepared the tub (or six of them to guard against accidents) plant a coffee seedling in each at the centre point of the junction of the sand and soil; the plant then has sand on three sides and soil on one.

At the end of twelve months take the plant that appears most vigorous, knock the hoops off the tub, and carefully wash all the soil and sand away from the roots. You will find very few feeder roots in the sand, while the manures are surrounded by a mass of them. As far as the roots go the plant is quite lopsided. Now if manures are put in alavanga holes, or in treaches cut a short distance from the tree, the roots are prepared to grow and develop in the soil enriched by them. But that terrible weapon the mamotte comes into play, and often cuts through the roots just when the demand for plant food is greatest, when the tree is opening crop. I most unhesitatingly condemn all mamotte digging. I have taken clods of earth after a mamotte digging, carried them home and washed out the fine feeder roots, often finding the clod one mass of them. Needless to say that on many estates leaf disease followed the digging when the trees were carrying crop. Except a light fork over at the end of July or in the beginning of August when the manure is put out, there should be no digging from the time the blossom sets till crop is picked. Every planter should do all he can to preserve his surface soil and save his tree roots. When the soil is light and friable and has been deeply and well cultivated from the beginning, the feeder roots are found at a much greater depth than when it is stiff and hard a few inches from the surface.

Deep fork digging once a year just after crop sends the roots down, and they are less affected by the sun and drought.

When rain falls in the spring, if the feeder roots are just below the surface a light shower will start the blossom, but may not be sufficient to set it, and if no rain falls for a month or so to back the first shower up, the blossom runs a great risk of being hurt. With deep cultivation this seldom happens, as the rain which is sufficiently heavy to reach the roots and bring out the blossom will also serve to set it, the sun not having the power to evaporate the moisture which is well down into the soil.

Superficial cultivation and want of manure are the main causes of the failure of crops to come on after a good blossom; the rain has run off and been evaporated before the trees had time to gather it to themselves.

Cultivate deeply, but not excessively, manure systematically, do it at the right time, keep the surface soil up to the tree, do not hump the roots by mamotte digging while crop is on the tree; in fact assist Nature, do not bully her, and good results may be depended on.

WILLIAM PRINGLE, M.S.C.I.,

Agricultural Chemist,

Bangalore, July 31st,

THE SCHOOL OF AGRICULTURE AND VILLAGE CULTIVATION.

We have received a copy of the following circular :—

The value of circulating leaflets, embodying useful and practical advice, has been proved beyond doubt, and the adoption of this means for disseminating agricultural information has been forcibly urged by the daily press. The free distribution of papers containing useful and practical advice has been favoured by Agricultural Departments wherever they exist, and has been attended with good results. In view of these facts the Editors of the "*Govikam Sangarava*" (the Sinhalese Agricultural Magazine, published in connection with the School of Agriculture) have, with the completion of the 2nd vol. of that periodical, decided on suppressing it for at least a time, with the view of testing the method referred to above, viz., of issuing monthly leaflets mainly intended for village cultivators, to be "sown broadcast" over the country. It is hoped that the minimum cost of 1 cent per copy made only to defray cost of printing, postage, and illustrations when necessary, will not be incurred by the cultivators themselves, but that those in authority who have the welfare of their several provinces and districts at heart, as well as influential, wealthy and philanthropic private land-owners, will give large orders for the leaflets and circulate them *gratis* among the villagers. In the absence of Itinerary Agricultural Inspectors, there seems to be no better means of presenting to the *goiyas* such information as they may be in need of, and the better for, regarding every branch of the Agricultural Industry. It will greatly facilitate the carrying out of this project, if all those who are concerned in furthering the interests of native agriculture, as well as cultivators themselves, will communicate with the Editors at the School of Agriculture, and suggest such subjects as they think might advantageously be taken up and treated of in the leaflets, and upon what points information is desiderated.

We hope that this new experiment will prove a successful one. Many of the *goiyas* will not be able to read the leaflets, and many more may not understand or appreciate the information they contain. But we trust the educated young men being scattered over the country will help their less favoured countrymen by reading, explanation and advice to follow as far as possible the reformed methods of cultivation which will, of course, be indicated.

TERMITES AT HIGH ALTITUDES.

For long shared what we believe is the popular impression that white-ants cannot exist at altitudes beyond 2,000 or 3,000 feet above sea-level. Tennent, indeed, wrote of their not being found above 4,000 or 5,000 feet; but until quite recently, we felt certain that at or above the latter elevation they did not and could not exist. To this effect we recently spoke inadvertently to a visitor on Abbotsford. We were aware that Mr. E. E. Green had observed and described a species in Pundaluoya at an elevation of over 4,000 feet; but we had never seen any in the district of Dimbula except some imported from Colombo in a deal case; and we regarded Abbotsford (4,600 to 6,000 feet) as equally exempt from the presence of white-ants as of land leeches. We had therefore that the more observant superintendent had noticed and told us of their existence. He writes:

"I now send you a sample so that you may be satisfied on the subject. If you cut up the sticks you may find more in them, but you may as well burn the lot after inspection, as it would be a pity to encourage their propagation. There are fortunately very few about, but still there can be no doubt they are

here. I got these on Knock Ferrol, and the last I saw there were altogether a much smaller variety." Of the smaller variety referred to, no specimens have been sent, so that the question of their identity with the small white-ant of the lowcountry cannot be definitely settled. If, however, we are correct in supposing that no earth-formed nests have ever been found at the higher elevations, the probability is that the smaller mountain termites is a distinct insect. The larger sized species, of which specimens reached us, in the twigs, into which they had bored tunnels on Knock Ferrol (5,200 feet altitude), are certainly distinct from the lowcountry excavators and pyramid builders, and Mr. Stanforth Green is probably correct in concluding that the big Dimbula ant and that of Pundaluoya are identical. Mr. Green writes :—

"The Abbotsford 'white-ants' are of a different species to the common termites living underground in the lowcountry. The former are much larger and whiter. It is likely however that they are to be met with in the lowcountry in certain situations. They do not seem to use cover in their work, merely tunnelling the wood they attack, and in which they reside. There is a smaller species in the lowcountry that sometimes attacks furniture and other wood-work. This species does not seem to reside underground at any period of its life. It is of an ivory-white colour.

"I cannot find E. E. Green's paper on the Pundaluoya termites, but they are probably identical with the Abbotsford ones." Tennent, on the authority of Thwaites of Peradeniya, describes a lowcountry termite (*T. moneeros*) which does not form earth nests but builds, in the hollows of old trees, nests which are of a black colour, resembling a mass of scoria; the insects themselves being of a pitchy brown. The question we should now like to have answered is, "Have termites been observed at a higher elevations than that of 5,200 feet?" As the creatures are, at certain stages in their existence, gifted with the power of flight, they may be able gradually to extend their zone upwards. Readers may remember the army of hornets which visited Dimbula and other high districts some years ago, just as tea was appreciably taking the place of coffee. They seem to have disappeared as rapidly as they came. The termites have no such powers of flight as the wasps.

BURMA RUBY MINES.

The third ordinary general meeting of the shareholders in the Burma Ruby Mines (Limited) was held yesterday at the City Terminus Hotel. Sir Lepel H. Griffin presided, and, in moving the adoption of the report, stated that it was accompanied by the report of a director (Mr. F. H. Kirby), who accompanied him (the chairman) to the mines a year before. Although they had no very brilliant results to show at present, he thought that their prospects were exceedingly satisfactory and reassuring, although they had not yet obtained stones of the quantity and quality which they hoped to get. Every month the returns were distinctly better, both in quality and quantity, and their chief engineer, Major Knubardt, was exceedingly confident of the eventual success of the company. In his last report, received a fortnight ago, Major Knubardt said:—"Briefly stated, I look upon our first year as having been one of exploration and experiment; the present, our second, year as one of development; and, as far as I can judge, our third and subsequent years will be years of success." He presented Major Knubardt's opinion to them as one deserving of their fullest confidence. He then recapitulated what had been done in the last 18 months, pointing out that in all such undertakings

there must be some experiments which were futile, especially in a country like that in which they were carrying on operations, and in a class of mining never before tried. To show them the great difficulty of transport he might mention that one of their large washing machines had cost no less than 21,000 rupees to be conveyed 60 or 70 miles from the river to the place where it had to be put up. After referring to the telegram, dated Rangoon, July 2nd, from *The Times'* Correspondent—in which reference was made to the present season being an unhealthy one throughout Burmah—the chairman stated that during the last few months the information which they had received showed that the company's staff were perfectly well. In his last letter Major Knubardt stated that he would require no money from England this year, and he felt quite sure that, unless any unforeseen expenditure occurred, this promise of their chief engineer's would be fulfilled. They had very largely increased the number of leases which they gave to native miners who did not interfere with the company's work, and the amount received under this head almost represented two lakhs of rupees per annum. This would be sufficient to carry on their works at Burmah without trenching on their supplies at home. The only machinery now going out to Burmah was several miles of rope-way—iron wire—which would be used for carrying the ruby-bearing earth to their stations. When the aerial rope-way was completed, Major Knubardt believed that their undertaking would be a success and a paying concern. It was his firm belief that the corner had at last been turned, and that an era of prosperity would shortly dawn for the company. Mr. George B. C. Levenson seconded the motion. At the request of the chairman, Mr. Kirby afterwards addressed the meeting, and spoke highly of the work which had been done by Major Knubardt, and expressed his conviction that, with a little more patience, exploration, and assistance, the company would be able to produce the finest rubies in the world. Major Joseph thought the directors should do their utmost to obtain a modification of the arrangement with the Government under which they would have to pay a smaller amount for rent, the sum at present being, he considered, most oppressive. Mr. E. K. Burstal inquired what experience Major Knubardt had had of mining, and whether any portion of his remuneration depended on results. He was sure that fleching occurred if the ruby-bearing earth could be touched by the natives. Having regard to the position of the company, he considered that the directors should forego a portion of their fees. He intimated his intention of proposing the following resolution:—"That, considering the very unsatisfactory character of the accounts presented to the meeting, the shareholders are of opinion that it is advisable to reduce the number of directors and the amount of their fees." The chairman, in reply, stated that Mr. Burstal's resolution could be dealt with afterwards on the proposal for the re-election of the retired directors. Major Knubardt was certainly not a mining engineer in the technical sense of the word, but the company's mines were not mines in the technical sense of the word. He was a man of all-round ability, and those who had been connected with the Government of India or public works there knew Major Knubardt's reputation as a most economical worker. They were now negotiating with the Government of India to reduce the rent as much as they possibly could. The question of the term of the lease would be taken up directly the question of the rent was settled. There was no doubt that whether they had a formal extension of the term or not, they had the right of continuing work at the mines as against all other comers, and this right had been and would be accepted by the Government. They could work the mines as long as they liked for 99 years. With regard to the proposed road to the mines, the Government had put it off from month to month. About a fortnight ago there was a telegram in *The Times* stating that another five lakhs had been sanctioned for expenditure on the road. He only hoped that this money would be spent and not be

swept into the Treasury at the close of the financial year, as had happened with other sums of money which had been sanctioned for the same purpose. With reference to the disposal of the rubies, the directors would be pleased to receive any suggestions from experts. It was a matter of great importance, but at present he was in favour of their being sold by public auction. It was not reasonable for the shareholders to expect the directors to work for nothing, but if they were dissatisfied they could at any time get rid of the directors. A shareholder observed that there were too many directors. The chairman, replying, said that this was a point which was about to come before them. The number of the directors and their remuneration were set out in the articles of association. So far as they now understood from Major Knubardt, all washing was done under the direct supervision of Englishmen. Mr. Lookhart, the late chief engineer, said he could not share altogether in the view which had been expressed by the chairman that the prospects of the company were satisfactory and reassuring. The question of centralization was this—the difference between working huge machinery at centres and small machinery distributed. He maintained that the latter plan was to have smaller machines, and that had such machines been sent out they could have been at work long ago, and results might have been obtained from all of them. He did not think that a dividend could be looked for within a reasonable and short time. He did not desire to say anything hostile to the directors, but he did not think they understood the position, and he thought they should ask a small committee, chiefly composed of technical men, shareholders in the company, to confer with them in regard to the method of working. The chairman, in further reply, stated that the object of the centralization of the work, of bringing all the earth to large washers at central stations, was really to do away with minute supervision at a great number of detached and separate places, and to allow the supervision to be exercised at main places, where it could be more precise and certain. The resolution was then carried. On the motion for the re-election of the retiring directors—Sir J. H. Morris and Mr. E. A. Gillam—considerable discussion ensued, it being contended that the number of directors was too large and that their fees were too heavy. The re-election of Sir J. H. Morris was also objected to on the ground that he is a director of ten other companies. The solicitor read the clauses in the articles of association relating to the number and election of directors—one clause stating that they should be not less than three nor more than ten—and pointed out that if the directors were not re-elected, and no one else was appointed in their stead, the retiring directors would remain in office for a year; while, as regarded the election of new directors, seven days' notice ought to be given by the shareholders. This view was dissented from by Major Joseph and other speakers. The Chairman said he could not put a resolution which was illegal, but he would take an expression of opinion from the shareholders as to the re-election of the retiring directors. He then put the motion, which was lost on the show of hands by an overwhelming majority.—*London Times*, July 11th.

PLUMBAGO MINING IN THE BENTOTA DISTRICT.—We were shown on Saturday a magnificent piece of plumbago found in the newly sunk mines of the Ceylon Gemming and Mining Estates Syndicate in the Bentota district. The specimen in its entirety scaled some fifteen pounds, and was discovered at a depth of ten fathoms, the vein giving promise of yielding an abundant supply of the mineral. Mr. H. Bettison, the engineer of the mine, leaves for England on Monday, and on his return will bring with him several Cornish miners, who will take up positions as overseers. The local agents of the Syndicate are Messrs E. G. Harding and Co.—Local "Independent."

THE BRITISH NORTH BORNEO COMPANY.

The 17th half-yearly general meeting of the British North Borneo Company was held yesterday at the Cannon-street Hotel.

Sir RUTHERFORD ALCOCK presided, and, in moving the adoption of the report, said that there had been a very considerable and satisfactory increase for 1890 in almost every item of revenue proper, more especially under the heads of "farms" and "customs"—two permanent sources of great importance. The increase for 1890, in round figures, amounted to \$100,859—namely, from \$251,002, in 1889 to \$353,461, in 1890. There had been an increase in the expenditure of \$82,950. But the increase on both sides of the accounts was partly caused by the inclusion, for the first time, of the revenue and expenditure of Labuan, and partly also by a modification in their system of accounts as explained in the report. With this explanation, there was sufficient ground for congratulation that in 1890, within ten years of the formation of the company, the receipts amounted to a sum of £101,665, leaving a surplus over the total expenditure of £19,238, subject to an amount to be provided for depreciation, differences of exchange, &c., of £1,355; and if such a surplus was not very large it would readily be admitted that, with a similar surplus in 1889, it was a great improvement on the budgets of the preceding eight years, and was of good augury for the future. The other source of receipts, the land sales, again in 1890 produced the satisfactory sum of £39,242, or very nearly the same as in the three preceding years. But owing to the present depression in the financial and commercial world, considerable returns under this head could scarcely be counted upon. An increase was apparent under almost every head of the expenditure account, but more notably under that of police, the upkeep of steamers, the necessity for a large surveying staff, and a new item for pensions, amounting to £1,225, chargeable to the revenue of Labuan which the company had to pay, having taken over the government of the colony with its revenue and liabilities. It was, however, expected that the island would be administered without loss, so that the item would be covered by the receipts. Since the last accounts were presented, the deed of settlement, at the request of the court and shareholders, having been amended by the Privy Council, the court was now authorized to deal with the monies derived from the sale of land in connexion with funds received from other sources, such as the revenue proper, and the balance of cash, therefore, had been passed to the general account, with the result shown in the balance-sheet. Negotiations had been proceeding for some time with the Indian authorities to obtain facilities for the emigration of natives of India to Borneo, and terms had been arranged definitely, it was believed, with the Indian Government. Independent of any advantages that might be reaped from an accession of labour from India, there was every reason to hope that the free labour from China now coming in and the improved sanitary condition of the tobacco estates would very shortly remove most of the obstacles hitherto encountered in obtaining all the supply desired, and of a much better quality. But tobacco, as he had often impressed upon the shareholders, was not the one resource of Borneo, nor would the ultimate success of the island as a colony be dependent upon the cultivation of tobacco for its prosperity. It had been abundantly proved that its soil, climate, and other conditions were favourable to the growth of many of the most valuable products of tropical countries which formed the staple of a vast commerce. These were all sources of great wealth, only wanting European enterprise to be developed into a great trade in Borneo. Having referred to several syndicates already formed with the object of encouraging this new trade, he said that, in addition to these enterprises, important concessions had been recently made which might be fruitful of large results. The most important of these was

one granted since the last meeting to a syndicate for the purpose of forming a railway company. There could be no doubt that the construction of a railway from the eastern to the western coast would confer a great benefit on the country and all concerned in its development. The administration of Labuan, under the company's management, was satisfactory, and the coal mines were being vigorously worked by the Central Borneo Company, which had put on a large steamer to trade between the island and Singapore. Mr. R. B. Martin seconded the resolution.

A long discussion followed, in which Mr. Cohen, Mr. John Martio, Mr. Spurling, Mr. Hildyard, Mr. Blundell, and others took part, the principal point considered being as to whether the amount received from land sales should be regarded as revenue and divided amongst the shareholders, or used as capital in the development of the company's enterprise. An amendment was moved by Mr. John Martio, and seconded by Mr. Spurling, to the effect that the meeting should be adjourned, in order that the directors might furnish a balance-sheet accounting for the proceeds of land sales in conformity with Article 82 of the deed of settlement.

On a show of hands being taken, the amendment was lost by 24 to 21, and the resolution was then agreed to.—*London Times*, July 10th.

NETHERLANDS INDIA.

The *Sourabaya Courant* takes note that the demand for waste land in the S. E. portion of Netherlands Borneo has taken the form of mania. It finds that the concessions of large tracts of land there, without adequate security that the applicant can readily turn them to account within a reasonable time, runs counter to the interests of cultivation. So liberal are the conditions for securing concessions, that they tend to work in favour of speculators who look up the land in hope of high prices. So much has the course of events taken this direction that in those parts of the country suitable for tobacco-growing hardly any land can now be had, and yet scarcely any of it has been brought under cultivation. It is evident that pioneer planters in that quarter, should their experimental cultivation succeed, may find that they can only increase their holdings by buying the required land from neighbouring speculators at exorbitant prices, and few will care to run the risk. Some of the concessions are in the hands of persons who mean business in tobacco planting, but so far not much has been done in this line beyond testing the ground.

Cinchona planting in Java seems to have seen its best days, for the prices of bark so continue to fall that several planters intend to close their estates as further working would not pay expenses.—*Straits Times*, July 15th.

AN IMPORTANT SURVEY IN BORNEO.

THE BOUNDARIES OF DUTCH AND BRITISH BORNEO.

H. M. S. "Rattler," Captain Hough, came into Singapore on Monday, after making a very important survey in parallel 4.10 N., in which territory, the limits and borders of the Dutch and British North Borneo Company's possessions have hitherto not been defined on a satisfactory basis. The "Rattler," just after returning from Wuhu, the scene of the recent riots, received instructions at Hongkong to proceed to Borneo in order to carry out the survey as ordered by the Lords of the Admiralty. She left Hongkong on the 16th May, and in company with the Dutch warship "Banda," Captain Von Owen, the survey of parallel 4.10 N. commenced on the Sibilik island. The result of the survey proved

conclusively that the British North Borneo Company have acquired the whole of the St. Lucia Bay and the two rivers Sri Negaras and Sine Soldang. These rivers were surveyed from the mouth right up to the source which was found to be eighteen miles away. They are in point of fact nothing more or less than a variety of creeks, with an unusual abundance of mangroves that run out for a great distance in the waters. It was discovered that this part of Borneo consists of one great delta, which makes it feasible for a traveller to go from South to North, by using creeks only, for a distance of over fifteen miles from the coast. There is a prevailing idea that by the means of these rivers the forest products of British North Borneo have been drained and smuggled out of the territory, across or down the rivers into the land possessed by the Dutch. The "Banda" and the "Rattler" have removed all the discrepancies that existed with regard to the demarcation of the two borders and indeed, when a comparison came to be made, it was found that the surveys of both parties corresponded in nearly every detail. The parallel latitude of 4.10 N. has been beaconed off with large beacons, with the Dutch flag shewing to the Southward, and the English flag shewing to the Northward, in every direction over the eighteen miles as far as these rivers extend. The whole place has been completely and satisfactorily settled by observation; and owing to the immense mangrove swamps, great difficulty was experienced in finding an observatory spot. The country in the vicinity seems to be devoid of fruit but there seemed to be any number of pigs and wild boar. The people on board the "Rattler" managed to get no less than eight pigs in one day which averaged when dressed, about 80 lbs each. The entire survey was completed in the course of a month, and then the ships came to Singapore.—*Straits Times*, July 15th.

PLANTING AND MERCANTILE NEWS FROM WESTERN INDIA.

(From a Correspondent)

Crops in Coorg this year promise well, but without doubt leaf disease is slowly and surely doing its full work, although not with the rapidity it did in Ceylon; despite what Messrs. Elliot, Pringle and Hunt and others, who you sometimes quote in your columns, may say. Mr. F. Noone, late of Sabonadière's, has joined Messrs. Akton Low & Co., and is stationed at Mangalore in charge of the branch there. As a Mr. Chisholm, a large proprietor in Coorg, who was down here the other day, said on hearing the firm had engaged him: "You Ceylon people are the 'Yankees' of the East. You gradually shove yourselves in, and then you fill your billets with other Ceylon men." The reply no doubt was: "The fact is, Ceylon is an uncommon good training ground for anyone connected with estates, and the eccentricities and amenities connected with a planting community."

BARK AND DRUG REPORT.

(From the Chemist and Druggist.)

London, Jul 16th.

CINCHONA.—The supply of bark offered at the fortnightly sale on Tuesday was less than on the last occasion, but the sales were almost as large, as the following figures show:—

	Packages	45% of which	Packages	41% were sold
Ceylon cinchona	45%	41%	do
East Indian cinchona	1,227	do	1,064	do
Java cinchona	25	25	do
South American cinchona	161	0	do
Cuprea bark	110	20	do

Total 1,981 do 1,533 do
At the previous les 1,579 cages were sold, equivalent

to 371,701 lb. of bark, whereas this week 343,011 lb were actually disposed of. There was no feature of special interest in the sales, and although bidding was at no time very animated, yet prices were on the whole firm. The unit is not quotably higher than it was a fortnight ago viz, 1½d per lb for unmanufactured bark. Ceylon and East Indian barks sold readily, nearly all that were not sold being taken back by the brokers on account of the bidding not coming up to their expectations, but in most instances there was a tacit understanding between certain bidders and the brokers. There was a large supply of cultivated Bolivian Callaya bark in firm large quills. Altogether there was 37,030 lb of it, mostly in good condition. The broker stayed scarcely 30 seconds in the pulpit over the lot, no higher bid than 6½ being reached, then, with a knowing look to a bidder, he bought in the 101 packages at 8d. Bidding "for the pile" was somewhat brisker than usual, and was going on uninterruptedly until the sales were half done, when Mr. David Howard good-naturedly said that "the room" must have some understanding as to how far that custom should go. It was not always a wise course to adopt; at any rate, they could not make a pile of one bale especially a bale so badly damaged that it could not stand by itself. The wisdom of these remarks was exemplified later when a broker was almost accepting a price for "a pile" some bales of which were afterwards sold at from ½d to 1½d higher than the price offered by the bidder for the lot.

THE LARGEST FLOWER IN THE WORLD.

In the farthest southeastern island of the Philippine group, Mindinao, upon one of its mountains, Paras, in the neighbourhood of the highest peak on the island, the volcano, Apo, a party of botanical and ethnographical explorers found, recently, at the height of 2,500 feet above the sea level, a colossal flower. The discoverer, Dr. Alexander Schadenberg, could scarcely believe his eyes when he saw, amid the lowgrowing bushes, the immense buds of this flower, like gigantic brown cabbage heads but he was still more astonished when he found a specimen in full bloom, a five-petaled flower nearly a yard in diameter—as large as a carriage wheel, in fact. This enormous blossom was borne on a sort of vine creeping on the ground. The native who accompanied Dr. Schadenberg called it bolo.

The party had no scale by which the weight of the flower could be ascertained, but they improvised a swinging scale, using their boxes and specimens as weights. Weighing these when opportunity served, it was found that a single flower weighed 22 pounds. It was impossible to transport the fresh flower, so the travellers photographed it, and dried a number of its leaves by a fire. Dr. Schadenberg then sent the photographs and specimens to the Royal Botanical Gardens, Braslau, where the learned director immediately recognized it as a species of Rafflesia, a plant formerly discovered in Sumatra, and named after the English Governor Sir Stamford Rafflesia. The new flower was accordingly named Rafflesia Schadenbergia.

The five petals of this immense flower are oval and creamy white, and grow around a center filled with countless long violet hued stamens, thicker and longer in the fertile flower than in the infertile.—*Gardener*.

DESICCATED COCONUTS.—In reply to your enquiry as to the number of nuts it takes to make up 100 lb. of the above, in case nobody has obliged you with the actual figures, you can I think reckon on 1000 nuts yielding between 300 to 350 lb. of desiccated coconut according to the seasons. It takes 1000 good coconuts to give 560 lb. of well-dried copra. But nuts before being desiccated are shaved of the brown outer covering of the kernel, and are dried more than copra over is.—*Copra*, local "Examiner."

NOTES ON POPULAR SCIENCE.

By Dr. J. E. TAYLOR, F.L.S., F.G.S., &c., EDITOR OF SCIENCE GOSSIP."

Sir Charles Mills and Dr. Edington have been visiting France for the purpose of inquiring into the best methods of guarding against and exterminating the phylloxera. South African vineyards are just now suffering grievously from this pest. Sir Charles has drawn up a report, in which he advises viticulturists to study French methods at Lyons, Montpellier, and Bordeaux. Dr. Edington describes the best methods of grafting and planting. He is about to return to the Cape, in order to be there before the grafting season begins. It is proposed to establish trial stations, in which the various kinds of American vines can be separately watched and tested. One kind, called riparia, is said to be absolutely free from and resistant to the phylloxera. These Cape experiments should be keenly and carefully watched by Australasian viticulturists.

M. Lesage, a French scientist, has just communicated the results of some very curious experiments he has been making on the influence of salt upon the quantity of starch contained in the tissues of the cress (*Lepidium sativum*). These show that when the plants were watered with solutions containing from twelve to fifteen grains of salt per litre the starch disappeared completely. The diminution of starch was proportional to the increase of salinity.

Mr. Storch, a German chemist, has been microscopically investigating the causes of "oily butter." He thought it might be due to some particular kind of bacteria, but if so he failed to find one. He discovered, however, that in all the butters he examined in which the "oiliness" was a marked feature there were always numerous fungi present, so Mr. Storch concludes they are injurious. A different organism was found in "tallow butter." Another probable flavouring of butter is that of "turnips," although made from the milk of cows which have not fed on those plants. This also is believed to be due to a special organism. The aromatic odour peculiar to souring cream is caused by a bacterium, and it is thought that butter having the same flavour owes it to the same cause. These microscopic fungi, therefore, give the flavours to our butters as well as odours to our wines.

It is now proved that the power possessed by plants to store up mineral substances differs much both quantitatively and qualitatively. The object of lime is to convert the poisonous potassium oxalate, which is found in considerable amount, into calcium oxalate. The assimilation of nitric acid takes place in the green cells of plants, and nitrogen migrates chiefly in the form of amides and amido-acids.

We have by no means learned all we can about ants, and we shall have to take Solomon's advice, and consider their ways a good deal more before we do, in spite of the researches of Huber, Lubbock, and M'Cook. The latest discovery concerning ants is that they are capable of parthenogenesis. This long word does not signify a crime—it only means that the female insect can breed for several generations without the aid of the male. It is a characteristic method of reproduction in the aphides, or plant lice. Several other orders of insect have members which occasionally or habitually adopt the habit, but nobody hitherto suspected ants. Professor Wasmann, however, has been enabled to induce two species of our common ants to become parthenogenetic by simply warming their nests in winter.—*Australasian*.

PLANTING IN PERAK.—The *Pinang Gazette* of 30th July says:—Negotiations are in progress for the purchase of five thousand acres of land from the Perak Government on terms as recently advertised. This large acreage of land will be brought into cultivation by the intending purchasers as quickly as possible, principally, we understand, with coffee and tea;

PLANTING IN TRAVANCORE.

We have had very complete returns sent to us by our Travancore friends for the plantations in the various planting divisions of the State. They are included in full detail in our Directory and the following summary made up thereupon indicates how tea is slowly but steadily superseding coffee and cinchona "over the ferry," as in Ceylon:—

TRAVANCORE:—AVERAGE OF PLANTATIONS.

1890	Cinchona.	Tea.	Coffee.	Cultivated.	Total.
Peermade ...	501	2,100	2,023	4,486	9,066
North and Central ...	377	2,898	596	3,871	16,530
Assamboor ...	215	1,020	1,378	2,800	7,918
Kannaadevan ...	1,941	270	160	2,231	4,017
	3,055	6,348	4,157	13,388	37,531
1891					
Peermade ...	310	3,321	1,356	4,987	8,589
North and Central ...	291	3,350	352	3,993	15,510
Assamboor ...	—	1,127	1,234	2,805	5,713
Kannaadevan ...	1,703	309	282	2,273	36,286
	2,304	8,106	3,204	13,558	68,093

Travancore has now 8,106 acres under tea, 3,204 of coffee, and 2,304 cinchona, making up a total of 13,558 cultivated acres out of 66,098 acres comprised in the properties.

THE CHINESE TEA MEN are reported to maintain a sort of incredulous nonchalance, even in the face of that almost complete capture of the English market by the Indian and Ceylon teas that appears to be impending. Consul Hopkins tells us that, in spite of the gloomy forebodings of foreigners, it is certainly true that the tea-men have not yet had the alleged gravity of the situation confirmed by any general lightness of their pockets since the transitional period began. They see Russian buyers pouncing at all the crack teas almost at any cost, and even buying up in London what they had not been able to secure at Hankow. Indian teas (adds Mr. Hopkins) are not indeed to the Russian taste, but the danger that threatens the teas of Central China comes from the rivalry of the Ceylon plant, the leaf of which gives a liquor, soft, pure, and delicate, suggestive of fine Ningchow, but preserving a character of its own.—*Indian*

DO TOOLS GROW TIRED?—This seemingly absurd question is seriously answered in the affirmative by a correspondent in a technical contemporary. He says:—"I called the attention of a shopmate—a grizzled old veteran—to the peculiar behaviour of a chisel. He looked at it and handed it back to me, saying—'The tool is all right, only a little tired. Lay it aside and let it rest. It will come out all right again, just as a man that is tired will.' I did not believe the old fellow, and I really thought he was crazy, speaking of a tool getting tired; but, as there was no help for it, the tool was laid away. I do not remember how long it was left to 'rest,' but when it was again sharpened and used it appeared to hold its keenest edge as well as it did before it got tired. Barbers tell me their razors, in constant use, get tired in the same way; and wood-choppers say their axes seem to grow soft all at once. Possibly constant and hard usage may cause changes in crystallization that would account satisfactorily for the peculiarity alluded to."—*British Quarterly Trade Review*.

THE GEOLOGY OF PUTTALAM.

The geology of Puttalam is of very considerable interest because of the undoubted accretion being made to the dry land by means of mud, sand, fragments of corals and shells and other substances swept by currents into the spacious lagoon known as "the Puttalam Lake." An observant correspondent writes to us on the subject as follows:—

"I have been much interested in the geology of this part of the country, I understand no fossils to have been found previously in Ceylon, except as coral. I found in a hard sandstone at Chilaw several shells, most of them well embedded in the rock, and of present date.

"I have also found a perfect fossil shell in what I believe to be a magnesian limestone, and apparently very much older than the present time. I am sending these down to you for inspection, and would like you to have them shown to any really good geologist. In my humble opinion the rocks enclosed are of later date than the coal formation, and I see no reason to doubt coal being found down in the lowcountry round here. We have no hills within 40 miles of this; the oldest rock found similar to Aberdeen granite is found 4 miles inland from Puttalam, but not so near the sea, at Pomparippu. I append a sketch showing where the rocks are found, and hope it may interest you.

"Plumbago is a siliceo crystallized coal, and if the heat &c. were not sufficient here to form crystalline rocks, such as gneiss &c., but only enough to form sandstones and magnesian limestone, possibly we may get coal in the natural state.

"In England I understand the formations run somewhat as follows—magnesian limestone, sandstone, coal strata.

"Here we find blue clay all about Puttalam for some miles. North we find magnesian limestone? Beginning on the coast line about 8 miles N. and running up the coast for 10 miles or so and then again inland, this same stone is found 24 miles north; the hard sandstone being found down at Chilaw. I have not found it more than a mile or so north of Chilaw."

The speculations of our correspondent about coal are of exceeding interest; and it would be a grand day for Ceylon if this valuable fuel substance were found in quantity. We are not, however, prepared to agree that plumbago, which a German savant traces to gas or water, whence it was deposited, is crystallized coal; the best geologists have abandoned that idea. We submitted our correspondent's letter to Mr. George Armitage, who has kindly reported as follows:—

RE SPECIMENS OF ROCKS SENT FROM PUTTALAM.

One specimen is a recently formed sandstone containing a shell embedded in it. This formation is found in the neighbourhood of Colombo about Hendala on the sea coast. [The curious and useful breccia known as "Pannagama stone," utilized to a considerable extent as a building material?—Ed. T. A.]

The other specimens are magnesian limestones, with appearances of fossils. Particulars of analysis enclosed. Your correspondent writes of sandstones and magnesian limestones as having been formed by heat. From his loose mode of expression it is rather difficult to understand his meaning. Sandstones and magnesian limestones are not formed by heat, but doubtless much of the Ceylon crystalline magnesian limestone has been subjected to heat. The specimen under examination has more of a crypto-crystalline appearance, and should be carefully examined for fossils if it is wished to fix the relative geological date of the formation. It is idle speculating as to what may or may not be found. The thing required is to work at the formations that one comes across and try and find the Geological boundary-lines, and dates when fossils can be found.

I shall send my theories of our plumbago formations when returning Mr. A. M. Ferguson's notes on the Geology of Nuwara Eliya.

Mr. Armitage's analysis of the magnesian limestone is as follows, and in quoting it we may say that this is the first time we have heard of dolomite, a much older rock than the ordinary coral limestone of the north of the island, existing close to the sea shore:—

ANALYSIS OF DOLOMITE FROM PUTTALAM.

- Hardness 3-5.
- H. Cl. in powder, soluble with eff. slight gelat. residuo.
- Filter. neutralized with Am. Liq. slight prec. Iron.
- A Portion treated Ox. Am. sol. copious prec. white Oxalate of Lime.
- A Portion treated Am. Phos. Soda Sol. copious white prec. Phos. Magnesia.
- The mineral is a Magnesian Limestone, Dolomite.

THE TALGASWELLA TEA ESTATE.

MR. E. S. GRIGSON'S REPORT.

We recently mentioned that Mr. Edward S. Grigson was visiting the Talgaswella estate; and a very lengthy report has just been distributed amongst the shareholders. He states that the property is only a few feet above sea-level, the climate moist and steamy, and therefore well suited to the cultivation of the tea plant. The rainfall averages from 180 to 200 inches per annum and is well distributed over the 7 months of the year. Some of the rising features of the land are a little exposed to the influence of the S.-W., monsoon and this year there has been more wind than usual, but it is nothing to speak of. The lay of land is perfect for tea, being easy and undulating throughout, with no abrupt features. The estate comprises 2,017 acres of which there are 485 acres of tea 3 years old and 196 acres 2 year old; and out of the balance it is estimated that from 500 to 600 acres are available for the furth

extension of the industry. The supply of timber and fuel is abundant and within reasonable distance of the cultivated area. Notwithstanding there is great irregularity in the growth and development of the tea, due to planting by village labour. Mr. Grigson says the yield next year should be about 180,000 lb. with a prospect of a little more if the season is a specially favorable one. This year the estimate is 90,000 lb., but the superintendent expects this to be exceeded. The average price obtained for such of the present crop as has been sold (37,490 lb.) is 46 per lb. nett. This, Mr. Grigson says, is a better result than would be expected from the low-country generally, and is therefore a feature of distinct promise. There has been nothing exceptional in the treatment of the bushes the desire being to get as much out of the tea, both old and young, as can legitimately be taken. The rate for transport of tea is 1½ cent per lb. delivered at Colombo; and the continuation of the seaside railway will further facilitate the transport of supplies and produce, already easy and inexpensive. In regard to labour the V. A. states that Talgaswella enjoys exceptional advantages. Sinhalese village labour is abundant. The wages are exceedingly moderate, the rates being: For men about 25c. per diem against Tamil 33c. women and children 6c. to 12c. against 15c. to 25c.; the average of the check-roll being about 18c. The cost of plucking to date is a little under 8c. per lb. of made tea, which may be reduced in future years to 7 and perhaps 6 according to the yield.

The jat of tea is a good deal mixed; and for a low-country estate Mr. Grigson thinks a finer class of hybrid might, with advantage, have been selected. No had seed, however, has been put in; the chief sources of supply being gardens of good local reputation. One field of the two year old tea was planted with transplanters, and being an excellent jat (Manipuri) is a clearing of distinct promise. Mr. Grigson concludes a very lengthy report by referring to the expenditure and receipts, and calculating the net value of next year's crop at 42c. says there should be a considerable surplus at the close of the 1892 season, but against this will have to appear the deficit of 1891, caused by the expenditure of about R13,000 for new machinery.

GRAIN CROPS IN CEYLON.

From the abstract of season reports for July 1891 published in the *Gazette* we learn that in the Western Province the paddy crop prospects were generally good, except in Kalutara and Panadura Totamunes, where there had been slight damage by floods, but fair crops were expected. In the Central Province also the prospects of the yala harvest were generally good, as well also those of kurakkan. The only exception was Udapalata, the report on which was:—"Yala fields where crop was ripening have been submerged or damaged by heavy floods on the 16th instant. Younger plants elsewhere have been damaged by insects." In the Northern Province the prospects and conditions of crops were generally fair. In the Kadagoda, Talpe, and Abangama divisions of the Talpe pattu the paddy crop was bad owing to want of rain and destruction by flies. In portions of the Matara district the crops were partly damaged by rain, and in some parts of the Hambantota district flies as well as rain had caused damage. From the Batticaloa district of the Eastern Province the report was:—"Cultivation for etalai nearly over: not quite so extensive as expected owing to long spell of dry weather and

four tank water will not last though ample for present requirements. Pinnari crops not yet threshed and brought to market. Price of paddy remains as in last month, viz., R1.45 in town market. Export of paddy coastwise over 56,000 bushels to date this year. Good sale of land for paddy under Chadayantalawa. Cattle hoof-and-mouth disease disappeared." From Trincomalee district the report was:—"Pinnari cultivation in progress, but condition precarious owing to short supply in tanks; as usual, rains have so far failed and weather very dry. Small cultivation in Katukulani has failed. Cattle healthy; murrain disappeared; no foot-and-mouth disease. Price of paddy R1.50 per bushel." In the North Western Province the conditions and prospects of paddy and fine grain crops were good. In the North-Central Province the condition of the paddy crops was good, and that of fine grain fair. From the Province of Uva the report was:—"Crops throughout Udakinda, Yatikinda, and Wiyaluwa exceptionally good, and weather for harvesting favourable. Crops in Wellassa and Butala promising. In Bintenna and Wellawaya the paddy crops damaged by flies." In the Province of Sabaragamuwa the paddy prospects were good or middling, except in Panawal Korale and Udawepalata of Lower Bulatgama, where the prospects were poor, crops having been damaged by recent heavy rains.

THE ORIENTAL BANK ESTATES COMPANY.

The fifth annual ordinary general meeting of the above company was held at Winchester House, Old Broad-street, London, on the 22nd instant. Mr. Alex. William Orichton presided.

The Secretary (Mr. Henry Greay) having read the notice convening the meeting—

The CHAIRMAN said: Gentlemen, I presume, as usual, that it will be your pleasure that the report and balance-sheet be taken as read. In placing this report and balance-sheet before you at this the fifth annual meeting of the company, we have some satisfaction in being able thus to close a year which has in its course given us and our managers some anxiety. Now, as to the causes for this, we have thought it right in our report frankly to state you—as, indeed, has been done by the directors of many other companies interested in Eastern produce this year to their shareholders—the difficulties which we have had to encounter, and which, though they may have been temporary and incidental in their nature, have still been made very remarkable by their coincidence and their combination. In the first place, as to Mauritius. In most of the districts of that island the yield of the cane in sugar was fully 20 per cent. below the average; and while on the one hand the sugar was thus deficient, the prices, on the other, obtainable for it when brought to sale, were exceedingly low. Nor were the reasons for these low prices far to seek. The money market had been in a state of violent fluctuation from September for some months onwards, and, besides this, reports were current that large shipments of beet sugar had been made from Europe to Bombay and Calcutta; and hence the fear arose that those and other available markets would be swamped and glutted. It was, in fact the truth that these shipments had been made. The experiment was tried some years ago and failed, but a further trial was resolved upon, and was made last year on a larger scale. That also failed, but, nevertheless, in the meantime, the effect of these reports and these rumours in Mauritius was to check all competition for, and speculation in, the native sugars, which were then just being brought for sale to the market. So that at the very time when every factory in the island—devoted as it is to the manufacture of sugar—was working long days, and in some cases day and night

and at the time when produce was being brought by thousands of tons into Port Louis—that market was in a state of panic, and buyers, being cut off as they were by want of telegraphic communication with the rest of the world, and bewildered by the reports received by every fresh mail, completely lost all their spirit and confidence. This, therefore, was one set of difficulties with which we had to contend. And then, again, secondly as to Ceylon. The report itself explains to you how the expense of the maintenance of our estates there was increased by the high price of silver remittances from Europe to the east. The average cost of the rupees was much above that of later years, and, consequently, except for any provision we could make by financial management to counteract this source of loss, the cost of laying down the rupees to provide for the upkeep of the properties was enhanced. If any further explanation is required of these matters, I cannot do better than to read to you an extract from an able address lately delivered on the same subject:—"The year under review has been an exceptional year as far as the crop is concerned. It looked promising for a considerable period, and it was only when the crushings took place that the result was found to be not only below the estimate, but considerably below the average. That was one of the circumstances we had no absolute control over, and the next to combine with it was that at the particular juncture when our sugars were sent to the market, there were violent fluctuations and uncontrollable oscillations of the silver market. This, gentlemen, coming exactly at the moment when our sugars were put upon the market, was of course most serious. I do not propose to go into the vast and wide questions connected with silver, but I will only point out to you that the effect of these fluctuations upon the result of the working of the year to us was this, that the expense in planting and maturing our crop and bringing it to the market was as though we had paid with half-crowns, and when we had to sell, we had to sell in florins." That, gentlemen, expresses the situation very clearly, and in connection with this there are some points to which I may advert in the balance-sheet. In that account, after the statement of capital, which is the same as last year, come the acceptances which are less by some £1,000 or £5,000 than previously; but the accounts payable on the other hand are more. This, however, is amply accounted for by the slow realisations of sugar from our own estates and those estates with which we are connected. Money was everywhere going out, and very little is coming in; but, besides this, if you look at the assets side of the account, you will see that the liability is fully counterbalanced there by the value of the stocks of sugar, tea, cinchona, cocoa, coffee, and cardamoms in hand, amounting to about £49,000. With regard to this I may here mention that we have placed the values of the stocks of sugar, tea, cinchona, &c., together this year instead of separating them in order to compare at a glance the values with the values put in the profit and loss account below under the head of "Produce in hand." With regard, then, to the much larger stocks of produce unsold and in hand this year than at the corresponding date last year, the state of things in the market in Mauritius amply accounts for it. The surplus produce consisted of stocks of sugar which could not till after some delay be realised, except at a great sacrifice. By waiting, as our manager has done, a great part has been satisfactorily sold, and soon very little sugar will remain unsold in Mauritius. I may also inform you that these stocks have been taken at very low prices, so that there is no doubt whatever as to the most satisfactory realisation. Not to detain you longer, the account closes with a balance of £15,222, as against £13,500 last year. And out of this we recommend you to declare a dividend at the rate of 7 per cent on the preferred shares and 5 per cent on the ordinary shares, in proportion to the amount of capital paid up. Turning back for a moment to the report, it is satisfactory to notice that the increase in the company's tea has fully carried out the anticipations which were made in the forecast

placed before you some years ago. And also it is satisfactory to note that the position of the company's tea with reference to the produce of other estates in Ceylon has been well maintained. We also mention improvements in manufactures. On our Britannia estate additional evaporating power has been added, and a large amount of canes can be treated other than the produce of the estate itself. The advantages of the system of the central factory are too well-known to need more reference. With regard to the other estates in which we are interested, you will be glad to learn that an exception to the common deficiency of the sugar crop, to which I have alluded, was presented in the case of the Beau Sejour Company's estate. That company usually makes a crop of something under seven and a-half million pounds of sugar per annum; but last year, that is, in the year under review, it made 8,800,000 lb. and it is expected that their crop will be a very good one this year. In closing these remarks upon sugar, gentlemen, I may point out to you the paragraph in which we mention that, after receiving the resignation of Mr. McDonald, we elected Mr. James Shaw, lately connected with the firm of Messrs. Parry & Co., of Madras, to fill the place on our board. I have no doubt that his name is well known to many of you as that of a prominent member of the Indian financial world, and also of the firm to which I have alluded. As such he has been interested for many years in the management of Eastern estates, and he is also conversant with sugar manufacture and with the details of sugar machinery. We expect the company will derive great benefit from his advice and assistance. In conclusion, gentlemen, the reports which we have received from our estates show that they are all in excellent condition, and that the managers are very hopeful as to the yields during the coming season, and I trust that a year of fair prices and good crops is before us. I now beg to move that the directors' report and statement of accounts to March 31st 1891, be, and they are hereby adopted.

Mr. James Shaw seconded.

Mr. Field asked for some explanation with regard to the entry of £2,800 on the debit side of the profit and loss account put down as "Balance of suspense account (stamps on share warrants) written off."

The Chairman said the cost of the share warrants had been placed to a suspense account, which they had been gradually writing off. The item of £2,000 now showed the writing off of the whole balance of that suspense account. They would be longer troubled with it henceforward. They were now quite free from the charge.

Dr. Lloyd asked if the directors could give the shareholders a list of the estates and details of the profit and loss each year.

The Chairman said he did not think it would be desirable in the interests of the company to give such information which might be made use of by competing companies.

A shareholder wished to know in the interest of the preference shareholders how much remained to be carried forward after the payment of the 7 and 5 per cent dividends.

The Chairman: The amount carried forward is £2392.

Mr. Setou said the shareholders would be glad to have an expression of opinion from the chairman as to the future prospects of tea in Ceylon. Those interested in Indian tea were regarding with some uneasiness the enormous increasing production of tea in Ceylon. It would be interesting to the shareholders to know what the chairman thought about the question of over-production. He was quite aware that China tea was falling off, but the production of the Indian article was rapidly increasing and Ceylon was coming on, and it seemed to him that unless new markets were opened up the result of all this production would be to cause a heavy fall in prices. He invited the chairman to express his opinion on the subject.

The Chairman said he thought the invitation given him to say a word on this subject was one which he should not accept if he took the advice

of the American gentlemen, who said "Never prophecy unless you know." He thought the question consisted very largely of price. He had already expressed on a former occasion an opinion at some length with regard to the production of tea. It was impossible, he thought, to make any accurate forecast. If four or five years ago anyone had said that the import of tea from China would have fallen to its present amount, he would not have been believed. He thought that the import of tea from China this year was not more than 60,000,000 lb., whereas some four years ago it was over 100,000,000 lb., and, notwithstanding the low prices, there was no reason why the whole of this or the greater portion of it should not, in the next three or four years, be discontinued altogether. Further, there was the fact that new markets were being opened. In America although the increase was perhaps not so very large, yet it was very promising. He thought from all the reports and information they could obtain that the increase would go on in several places in America. Besides this considerable progress was being made on the continent. The prices, of course, would depend entirely on the supply in the London market as compared to the demand, and it would entirely depend upon how much tea was taken for other places what these prices were to be. That was the reason why it was impossible for them to make a forecast. He thought that looking back at the past if they had been governed by these considerations, they might have said, "If the yield of tea is so much now, in a few years time there will be a visit over-production in the market?" That had not turned out to be the case. Notwithstanding the vast increase in production there was a very fair market. In all these things they had only to go on and endeavour to reduce their expenses as much as possible, and to produce the best article. That was the course they had adopted before, and which they must follow now and follow with courage, and trust in the future. He did not think in declaring the dividend they had, they had been rash or sanguine; on the contrary, there had been complaints that it had not been larger. But they were in a position, as he had shown them, to pay the dividend and to put by a substantial amount, and at the same time to write off the balance of the suspense account.

The Chairman then put the resolution for the adoption of the report and accounts, and it was carried unanimously.

The Chairman then formally moved the payment of a dividend in accordance with the recommendation in the report. Mr. Shaw seconded, and it was adopted unanimously.

The Chairman then proposed that the retiring director, Mr. G. H. Tod Heatly, be re-elected. Mr. Rohde seconded, and it was carried unanimously.

Dr. Lloyd proposed the re-election of the auditors, Messrs. Welton, Jones, and Co., at a remuneration of fifty guineas. Mr. Phillips seconded, and it was adopted unanimously.

Mr. Field proposed a vote of thanks to the chairman and directors. A satisfactory statement had been put before the shareholders, and, generally speaking, fair progress was being made. He hoped, however, they were approaching the time when a higher dividend than 5 per cent. would be paid on the ordinary shares. Mr. Lloyd seconded, and the resolution was carried with acclamation.

The Chairman suitably acknowledged the compliment, and the meeting terminated—*L. and C. Express.*

A SUGAR ESTATE IN BARBADOS is graphically described in an article contributed to the *Gentleman's Magazine*, which will be reprinted in the *Tropical Agriculturist*. Although sugar has almost ceased to be an industry of any consequence in Ceylon, yet our planters will be interested in a product and conditions so different from their own, while all who are engaged in sugar culture will read the article with pleasure and we trust with profit. Barbados, like the Jaffna Peninsula, consists of coral rock, and there, as here, there is the curious phenomenon of rich red soil overlying the white limestone.

TEA IN DARJILING THREATENED BY LOCUSTS.—Such is the news given in a telegram quoted from an Indian paper in another column. We may be thankful that in Ceylon we have not the locust plague to spread destruction such as is now being experienced in Northern India and in Egypt.

TEA FACTORIES AND ELECTRIC LIGHTING.—The buildings on the New Peradeniya estate, which belongs to the New Peradeniya Estate Company, are to be lighted with electricity, permission having recently been given by the board of directors in London. Those in charge have also offered to light the new Peradeniya railway station which adjoins. The railway authorities, however, may consider that there is not sufficient business at this small station to agree to its being placed so far in advance of any other station on the line in the matter of illumination. Mr. R. Anderson is the resident superintendent on this splendid estate, and Messrs. Edwards & Co. are the agents of the company. There are already two, if not more estates in the island which have the electric light in their factories.

MR. W. H. TREACHER.—We had the pleasure of a visit today from Mr. W. H. Treacher, C. M. G., so well-known as Governor for several years of British North Borneo, and latterly as Secretary to the Government of Perak. Mr. Treacher looks wonderfully well considering the number of years he has been in the Service, and purposes to return after a short leave of three months for a further spell of work. He tells us that the whole of the 10,000 acres of land offered on special terms to pioneers in Perak have been applied for, four or five of the lots being taken up by Ceylon men. The reports we have had of the steady progress made in Perak are fully confirmed by the Secretary to the Government, though mining operations are not particularly brisk. The progress of British North Borneo, which at one time was said to be the "new Ceylon," is naturally enough watched by Mr. Treacher with great interest, and his unexpectedly meeting with his old colleague, Mr. Henry Walker, now staying here on his way out, is one of the happy incidents which have made his brief stay at Colombo a pleasant one.

RETURN OF MR. SANDISON FROM JAVA.—Mr. W. G. Sandison, of Sana and of travelling fame, returned to Colombo in the "Onléonico" today from Java, whither he went on a business trip six weeks or so ago. Mr. Sandison, it will be remembered, had visited Java before—some time ago—but his trip then chiefly had reference to cinchona; and it would seem that the Dutch cultivators had not forgotten the call that he then made, for he says that, while individually they were very hospitable and seemed glad to see him, there was a sort of suspicion about them as much as to say, "what are you doing down here, now?" "You see," he adds, "my first visit was in connection with cinchona, and I didn't do them much good over that." The object of this Mr. Sandison's second visit was to dispose of some of his Sana tea-seed and to extend its sale among the planters there. With this object he visited Preanger, the most famous planting district in Java, and he says that at Tjisalak especially he found a Dutchman who seemed to be a go-ahead man and who took much interest in the Ceylon seed, while the lay of his land, Mr. Sandison says, was such that nothing in Ceylon could beat it. The Dutch cultivators, he believes, are beginning to slowly realize the advantages of high-class seed, such as Ceylon or Assam, as opposed to the ten they have hitherto been accustomed to plant, namely, the Obiense jat, and they are being forced to recognize it by having to keep the produce of the two jats distinct, which naturally involves much trouble and labour. However, the fruits of Mr. Sandison's visit have yet to be seen, as at present he has not succeeded in doing anything more with the Java planters than induce them to experiment with his seed, and on the result of certain experiments which Dr. T. C. of the Botanical Gardens at Buitenzorg is going to carry out with some of the seed he took down, Mr. Sandison says a great deal depends. For the present, Liberian coffee is all the rage in Java; but *helopeltis*, he adds, is giving the planters just the same bother as before.

QUININE.

(From C. F. Boehringer & Söhne's Report.)

WALDHOF NEAR MANNHEIM, July 1st, 1891.

Quinine during the first month remained stagnant. Speculators retired from the market, while the consumption that for the first five months of the present year had been very large, showed some abatement. Secondhand holders are now again selling quinine at rates lower than it costs to manufacture at the present price of bark.

The London public sales of bark have considerably diminished in dimensions, and are likely to decrease still further for the next few months, the supplies from India which have formed the chief item of late always falling off in the second half of the year, while Ceylon in 1891 will hardly contribute more than 5,000,000 lb.

For the next Amsterdam sales of the 18th instant some 340,000 kilos with over 460,000 ounces of sulphate of quinine are anticipated. The following sales take place only on the 3rd September. Export of Bark from Java.

	Amst. lb.
from 1st July 1890 to 13th June 1891	about 6,550,000
" 1890 to 31st May 1890	4,604,741
" 1888 to " 1889	3,847,845
" 1887 to " 1888	2,630,164
" 1886 to " 1887	2,054,025

An association or trust of bark growers is again talked of. This time the Java planters are going to manage it themselves. Whether they will succeed remains to be seen, the movement however, seems to indicate very clearly that at present rates cinchona planting hardly pays even in Java, and if some few plantations have nevertheless made a dividend, it has been owing to quite exceptionally favourable circumstances.

Mr J. E. CARNE, mineralogist to the Department of Mines, Sydney, has made a discovery of precious opal at a spot known as White Cliffs, about 50 miles north of Wilcannia, in the western part of New South Wales. The opal is found in crevices of sandstone and fossil wood, occurring in a formation resembling the Desert Sandstone beds of Queensland. Sometimes, too, it is found disseminated in a kind of cement which has penetrated the mass of body of the sandstone.—*Colonies and India.*

THE PALM-OIL DISTRICTS OF AFRICA.—At the evening meeting of the Royal Geographical Society on Monday Mr. A. Millson read an interesting paper on a journey to the Yoruba country, in which most of the palm-oil shipped from Lagos is produced. "Of the future commercial development of so rich a country," said Mr. Millson, "much is to be expected. During my visit to Ibadan and Ikirun palm-oil was selling at the rate of 3/ 15s a ton, and palm-kernels at 3/ a ton, the prices in Lagos of these staple articles of West African commerce varying between 17/ 10s and 23/ a ton for oil, and 9/ and 10/ a ton for kernels. Small tusks of ivory were selling at Ikirun for 6d a lb. and large ivory could have been bought at very low rates had I been able to transport it in my baggage. The gravel ridges, which alternate with the richer lands, were covered with sheabutter trees, which yield a valuable vegetable oil, the water courses were shaded by gum-bearing acacias, ozea-gum trees, and camwood trees, while the forest-lands of Ijebu and Ijeha contain numerous valuable timber trees. In addition to the above products of the country, there are many minor articles of commerce, such as tanned skins, groundnuts, and dyes, while the most important consideration of all, in my opinion, is the future development of good qualities of cotton, coffee, cocoa, and other valuable plants, which are rapidly being introduced among the natives. When I state that over 80,000 young plants—cocoa, coffee, kola, coconut, and other economic trees—have been distributed since the month of May, 1888, by the Botanic Centre of the colony of Lagos, and that over 60,000 of these were eagerly purchased by the natives, it will readily be understood that one is not in error in counting upon their keen interest in agriculture as a means of profit as well as of actual maintenance." The lecturer proceeded to state that the principal use of palm-oil was in the soap and tinsplate making industries. The mention of the latter industry as an outlet for palm-oil appeared to create some sceptical amusement, and inquiries were made, but could not altogether be answered by Mr. Millson, concerning the use to which palm-oil is put in tinsplate-making. As a matter of fact Mr. Millson was perfectly correct. Huge quantities of palm-oil are annually consumed in the tinsplate-works

of South Wales and elsewhere, the heated iron being temporarily immersed in hot palm-oil prior to its coating with tin, in order to prevent it from oxidising. For this purpose the best soft 'Lagos oil,' which contains least impurities arising from its preparation from the rotten husk, &c., is, we believe, most frequently used. In 1880, when the British Pharmaceutical Conference met at Swansea, the members were taken over some large tinsplate works, where they witnessed the use of oil in this manner, and they will probably have a similar opportunity of verifying the statement at their forthcoming reunion in Cardiff.—*Chemist and Druggist.*

SUGGESTED CITRUS-CULTIVATION IN EAST AFRICA.—The island of Corsica has long been famous for the excellence of its "cedrats," or citrons, the superiority of which in size and aroma is attributed to the richness of the Corsican soil in ferruginous and other mineral constituents and in certain salts. The cedrat-orchards, to yield a good crop, require to be situated at a low altitude, to be protected by hills from the cold winds, to be absolutely safe against frost, and to be properly watered twice daily during the dry season. Cedrat-growing, to be remunerative, requires extreme care, and the trees are subject to many diseases which must be guarded against; but, if these conditions are fulfilled the industry—especially that part of it which consists in pickling the fruit for the market—is extremely profitable, the crop of a single untried tree being worth as much as 10l. to 12l. per annum. The fruit is prepared for the market by slicing it in halves and pickling it in brine—i.e. salted sea-water. It is then sent to Leghorn to be candied in sugar, while the best fruit is pickled whole and used as a table delicacy all through the East. The Italian candying factories obtain so large a drawback of duty on the sugar which they use that it is equivalent to a bounty. Consul Malcolm Drummond, of Ajaccio, while guarding himself against the expression of a definite opinion, thinks that it would be well worth while to try the experiment of acclimatizing the Corsican cedrat in our East African colonies, where the high lying valleys on the mountain slopes would, he thinks, form an excellent position for conducting a series of experiments in cedrat and lemon culture. No great outlay would be necessary for the establishment of an experimental plantation.—*Chemist and Druggist.*

BOVUS COFFEE.—The arrest of two men at Lille for manufacturing coffee has led to an investigation of their methods. Their plant, estimated to be worth 50,000fr., and a large stock, were seized. The following is briefly the method of manufacturing this coffee. The raw materials are composed of chicory flour, and sulphate of iron in powder, the latter giving the necessary colour. The paste made with the mixture of these materials is enclosed in a cylinder and then pressed with an hydraulic motor. Through five different openings it comes out in pieces measuring 30 to 35 centimetres in length by 4 millimetres in thickness and 18 centimetres in width. These are again powdered with flour and immediately placed between two metallic punching plates before cutting each piece in such a way as to give it an almost perfect resemblance to natural coffee. The two men employed in their manufactory eleven men and seven women, the latter having to separate the berries which were not properly moulded from the others. These producers have arrived at such perfection in France that some deputies have just laid a measure on the table of the French Chamber, respecting the article which runs as follows:—"It is forbidden to expose or place on sale, to import or export any manufactured product which, by its shape, colour, general aspect, is capable of being confounded or bought as coffee in green or torrefied berries." The other articles set forth the penalties:—50 francs to 3,000 francs, five and three months' to a year's imprisonment; penalties to be doubled if the product is recognised as baneful to health, or if it has been fraudulently mixed with natural coffee &c.—*Home & Colonial Mail*, July 3rd.

TROPICAL CULTIVATION IN THE NORTHERN TERRITORY OF SOUTH AUSTRALIA.

Mr. M. W. Holtze, who was appointed to succeed the late Dr. Schomburgk as Director of the Adelaide Botanic Gardens, arrived from the Northern Territory on Friday. Mr. Holtze has been in the Territory for eighteen years, and has had the direction of the Experimental and Botanical Gardens at Palmerston, and his views on tropical cultivation, from which his new appointment practically cuts him off, are interesting.

Mr. Holtze, who by-the-way is a cultivated, scholarly representative of the great country which had the credit of producing Dr. Schomburgk, gave one of our reporters some idea of the experiments he has carried on in the Territory. Experiments have been made with all sorts of tropical plants, and Mr. Holtze has proved incontrovertibly that under certain conditions these may be profitably cultivated in the Northern Territory.

Mr. Holtze regards it as certain that with Asiatic labour rice, tobacco, sugar and coffee could be cultivated in the Northern Territory on a large scale, and profitably too. The public, however, are shary of investing capital because owing to various reasons so much money has been sunk in what has therefore been termed "Our white elephant." Now Mr. Holtze thinks the Government might carry on experiments to prove that the tropical plants mentioned can be profitably cultivated, and he avers his willingness to go back at once to manage a plantation if the Government would carry out such a scheme. It might, he thinks, be done on that of loan money, and not more than £25,000 or £30,000 would be required. It would undoubtedly pay handsomely, but beyond that the effect it would have in influencing capitalists to lay out their money would be incalculably great. The land laws of the Territory are now considered satisfactory—that is, of course, those contained in the Act passed last session. But Mr. Holtze has an idea which the Government might carry out. It is with regard to cocoanut-palms, which could be grown profitably in the Territory. If a man were given a fifty years lease of land on good terms he could plant those palms to the number of seventy an acre. He ought to get the land at a nominal rental for ten years on condition that he planted a certain number of acres. At the end of ten years the rent ought to be increased, or the lessee might pay a royalty to the Government. Cocoanuts could be grown very profitably. In Ceylon each palm yields a profit of two shillings, so that an acre will give a profit of £7. There is an almost unlimited market. Ceylon annually exports a million pounds' worth of cocoanuts besides consuming quite as many. The market for it is increasing as excellent coconuts are now manufactured in Germany from the nuts. Mr. Holtze has planted 600 palms at Palmerston, and they are thriving excellently.

Mr. Holtze believes in the Territory as a field for small capitalists. They could do better than grow wheat. Let a married man, either with or without children, but if he had a couple of boys they would be helpful, and a capital of say £500, as many farmers have, go to the Territory. He could plant tobacco on say ten acres of land, which can be taken up on easy terms and could make a profit of £400 a year—that is with coolie labour. Then as he went on he might plant coffee and more tobacco, and before long would be well to do. Of course some knowledge of the cultivation of tropical products would be necessary. Now is an especially good time to push ahead the growth of these products there, because the Queenslanders are having trouble about labour.

"Coolie labour is absolutely necessary in the Northern Territory," says Mr. Holtze. "White men can work there. I have done every kind of work myself, and am none the worse for it. It would, however, be an

* Nearly a million pounds worth of various products of the palm.—Ed. T. A.

insult to offer any white such wages as would make cultivation profitable to work there. No, we must have coolie labour. Chinese can work as well as coolies, but they are too cunning and too independent. As soon as they get a £5 note together they are on their own account, and we don't want that. Coolies, however, would suit our purposes better, and they could be obtained, and would work for wages that would make cultivation of tobacco, sugar, and coffee profitable. The Coolie Immigration Act, which is now on the Statute Book, is inoperative, because so much money is swamped in red tape. There are too many officials provided for. I see no reason why the Government Resident could not represent the Lullian Government in the Territory, while we had a prominent lawyer or merchant to look after our interests in India. The immigration of coolies will never pay it officials are to receive £3,000 or £4,000 a year. And we must have coolies. They would not be any trouble either, and there would be no fear of them going South."

Tobacco, coffee, sugar, and rice could be profitably produced in the Territory. Rice, however, only by Chinese labour. That valuable article of diet, Mr. Holtze is positive is a native of the Territory, where it grows wild. He has visited Saigon, the great rice-producing district of China, and the soil and climatic condition of the country are exactly similar to those of Saigon. The tobacco already grown by Mr. Holtze is of superior quality, and cultivated on a large scale would be profitable. Mr. Otto Brant has grown some. At first, owing to faulty cultivation, he was not successful, but experience taught him just as it does all those who settle in a new country, and now the tobacco plants are looking excellent. There is no doubt coffee and sugar can be profitably grown, although sugar is at such a low price. Besides these four largely consumed articles almost innumerable other tropical products not so much in demand could be grown. What the country wants are men with capital and intelligence.

The new Director has had a hurried look through the Botanic Gardens, and he quite anticipates having to make alterations. But, though he dares to tread in the footsteps of such an eminent botanist as his predecessor, it will be with care, and Mr. Holtze will not carry out any vital changes in the Gardens until he has thoroughly studied the circumstances. He expects some exceedingly hard work. One thing Mr. Holtze intends to do. It is to take pupils in gardening at the Gardens if the Board of Governors will allow him. He proposes to his own time to teach them enough of the elements of Latin, German, and French to assist them in their botanical work, and to instruct them in general work about the gardens. They would have to study more or less by night. The boys who would be with him two or three years would receive a small salary, and in the end would be turned out fit to manage large private gardens with credit to themselves and satisfaction to the owners.—*Adelaide Observer*.

[The Northern Territory of South Australia and Northern Queensland ought to be made Crown Colonies and cultivated by coolie labour, if they are to advance. Happily, perhaps, for us, the whites will not permit the presence of black labour.—Ed. T. A.]

PLANTING NOTES FROM COORG. MR. PRINGLE'S LETTERS.

Coorg, July 18th.—The monsoon throughout June was extremely light for the time of year. The amount of rainfall for the month gauged at Muroora was 12 inches 83 cents, against 22 inches 6 cents during the corresponding period of last year—and last year's was a light monsoon. The total rainfall from the 1st January to the 30th June, 1891, was 25 inches 43 cents, against 32 inches 99 cents for the same period of 1890, thus showing a deficiency of 7 inches 56 cents, which is much under the average for the past 10 years. Rain from the southwest quarter set in for the first time on the 2nd June in thin spray-like showers, which continued throughout the month at intervals during

the 24 hours every day, and as there was plenty of sunshine it was just the sort of weather to give rise to the steamy heat under shade which, according to Mr. Pringle, is so conducive to the inception of leaf disease. The ominous specks have shown themselves on trees weakened by heavy bearing last season and on others by the attacks of the borer grub. On the 30th ultimo the rain set in very heavily and continued uninterrupted till the 10th instant, when there was a change, the amount registered for that day being only 46 cents, as compared with an average fall of 2 inches 81 cents, from the 1st to 9th instant, both inclusive. The heaviest fall was on the 5th, when 5 inches 88 cents were registered. There was a small respite after the 10th, which continued till the 18th when the rain started heavily once more, only again to stop on the 16th, since when there has been a welcome break which promises to hold out for some little time. The total fall of rain gauged at Mercara from the 1st to the 10th instant, both days inclusive, was 21 inches 24 cents. All this heavy rain has come most opportunely for the paddy fields. The ryots were complaining that their nursery beds were drying up for want of water; but now they are quite satisfied, and ploughing operations are being prosecuted briskly. It is surprising what a difference every few miles inland east of the ghauts makes in the rainfall. The average rainfall for the past 10 years in Santacappa District, only 9 miles east of Mercara, is about 65 inches, whereas in the latter place it is more than double that amount.

Labourers, have been slow in putting in an appearance from South Canara this season, owing to the rain having reached them late. Their presence on estates just now is very welcome as the latter are mostly in a very bad way, with weeds and grass hiding the trees from view, supply planting and the taking out of borer being at a standstill. New clearings especially are in a wretched state of weediness, and all that can be done now is to get the weeds under at any sacrifice, supplying, &c., being secondary considerations. There are a few fortunate places where labour is sufficiently abundant to carry on all branches of work that ought to be done at this time of year; but the majority of estates are badly off. It is owing to this constantly recurring failure of labour at the right time which retards such an all-important work as supplying up vacancies, and sometimes causes it to be neglected altogether with the results, seeing the losses sustained through borer, that they come to present a rather bare appearance in parts. What makes us especially sore on this question of labour is that heavy advances are given out to contractors who never hold to their contracts. It appears to have come to be an understood thing that Canarese labour from the Mysore country is not to be looked for till September, in spite of increased wages, registration of Maistries and what not. And in a few years I believe we shall have to depend mainly on South Canara and Malabar coolies for the working of our estates. These coolies, for the most part Wolians and Parleys, are in a state of abject slavery in their own country. The large landholders there exercise a proprietary right over them and merely provide their marriage and funeral expenses, food and a few rags at times in exchange for their labour. For such faults as evading or shirking work, shamming sick, &c., they are visited with the severest punishment, which usually consists in the delinquent being tied to a tree and having the chastening rod laid on him with very little regard to mercy. These people are allowed by their owners to come and earn a few rupees on coffee estates after all their paddy field work, &c., has been completed; but were betide them if they are not back in time to reap the paddy. They know what would be in store for them, and hence it is almost impossible to keep them here even a few days after the end of September. Their usual time for coming in is from the middle of July to the middle of August, so that unless they come in swarms they can't be relied on for much. They are fairly good at weeding, digging and manuring, but for such works as handling, pruning, &c., which require skill, intelligence and the exercise of some judgment, they are next to useless. They do pretty well, however, when tutored by Canara

coolies. They are such an apathetic, indolent, depraved lot that I am afraid any exertions on their behalf, like that inaugurated in Madras on behalf of the Pariah, would be utterly futile. They usually return again at the end of November and work on till the end of February, when they begin to be wanted once more to reap a second crop of paddy. There are other high class coolies who come from South Canara. They consist of Bhuntas, Moplahs and petty landholders, or Gowdas; but they generally follow in the wake of a contractor, who takes up work at so much per acre. It is really astonishing to see the amount of certain kinds of work these people are capable of doing; opening out vines, for instance. I have known some of them to do 2½ times as much as an ordinary cooly, working from early in the morning till evening, and they are paid accordingly. The Moplahs especially are fine specimens of men and very hard workers. From what I have seen of them, I believe they ought to furnish splendid fighting material, and it is to be hoped some notice will be taken of your advocacy of the scheme of raising regiments from them.

Circumstances over which I have had no control have prevented me being regular with my contributions of planting notes, and noticing the remarks of Mr. Pringle, which were the outcome of my notes of the 19th May last. He complained that I had not given him credit for the discovery of a remedy for leaf disease. The information that had reached me was to this effect—if it was wrong I owe Mr. Pringle an apology. I should have been the last person to have withheld the meed of praise that was his due had I known that his efforts in this line had been crowned with success. Not knowing, I should have held my peace; but my information has been startlingly corroborated by no less a person than Mr. Meynell, Messrs. Matheson & Co.'s representative here, in his letter to the *Mail* in which he quotes from Mr. Pringle's letters to himself to show that, according to his own confession, the results he had obtained were doubtful. Mr. Pringle replied to this letter, but it was noticeable that he did not explain away the somewhat damaging quotations from his own letters to Mr. Meynell. I can understand the difficulties under which Mr. Pringle laboured as he had not got a proper spray-diffusing machine till last February, and as leaf disease is not very prevalent during the hot months, he had not an opportunity before he left of testing his remedy on a large scale. I have no doubt that Mr. Pringle has every reason to believe in the efficacy of his remedy, but planters want to see the result of the experiments he has instituted on Messrs. Matheson & Co.'s places before they commit themselves to any line of action to secure his services for their especial benefit. Mr. Pringle has done inestimable service to the country in showing what uses burnt soil can be put to, and also in showing that manure is best put down broadcast so as to insure its equal distribution all over the land. The method in vogue not so many years ago was to scrape a saucer-like hollow from 3 to 6 inches above the trees, put in the manure and cover it over. I am not so sure that this is not practised even now on some places. It is needless to refer to the absurdity of the thing. Mr. Meynell's assertion that beyond keeping estates alive manure is of no use, has caused some amusement amongst planters, the large majority of whom can't agree with him. It is a fact there is no getting over that places which are systematically manured are paying a great deal better than those that are not. There are two pieces of coffee in Mercara on the poorest land imaginable, which were raised solely by manure. One of these has been for a long time old coffee. Mr. Meynell must be aware of its existence, and will he say that it would bear from 12 to 15 cwt. of crops as it does without manure?

Mr. Pringle does not agree with me that Iberian coffee in Coorg would prevent a disease and a snare, and asks me whether I have seen the trees on Mr. Hamilton's estate in the forest or those at Tamer-Holler (probably Thuniro Hall's Canarese, Coldwater Hollow, is meant) and say that if I did I would not speak 1 cwt. an acre being difficult to get. It is rather too much to ask Mr. Pringle to look up the file of the *Mail* and refer to my notes of the

19th, but if he did he would find that he has made a slight mistake; that what I did say was that Liberian coffee crops closer 1 cwt. an acre than 20 cwt. as some have asserted in print that it would. He simply corroborated what I said, in putting the yield at 5 cwt. an acre. I have had not the pleasure of seeing the trees referred to, so it would be interesting to know how many acres are under *Liberica* in both instances, as to frame a conclusion from a few trees carefully tended would be unsound. It is quite possible that there may be a few spots in Congo where the necessary conditions for the successful cultivation of Liberian do exist, but it does not follow that success would attend its adoption on all the places now devoted to *Coffea arabica*. The latter, even now, in the face of leaf rust and the other ills that coffee is heir to, will with good work and manure, give its 5 cwt. on an average with ease and comfort, and so long as this is so evils that we wot not of are best left alone.

The rain has started again today.—*Madras Mail*, July 22nd.

NOTES ON POPULAR SCIENCE.

By DR. J. E. TAYLOR, F. L. S., & C., EDITOR OF "SCIENCE Gossip."

It is not an infrequent thing to be asked by farmers who do not know too much of agricultural chemistry whether the sun has any influence on "artificial." At first, one is disposed to answer—"Certainly not." But M. Laurent has recently demonstrated to the Brussels Academy of Science, that nitrates can be decomposed by the action of sunlight. He proved this by causing a beam of sunlight to fall upon solutions of nitrates placed in a vacuum, and found that after a certain time the space contained liberated oxygen, whilst the liquids possessed the characteristic reactions of nitrates. The blue end of the spectrum was found to possess the most powerful reducing action.

It is the function of economical science to recognize, no such thing as waste. Lord Palmerston defined dirt as being matter in the wrong place. What we call waste is something useful or valuable in the wrong place. Forty years ago the gas companies were steeped to the lips in law suits taken to prevent them throwing their "waste" into the rivers and canals. They were forced to utilize it. Out of that very waste chemical science has manipulated the most wonderful and diversified products—brilliant dyes, delightful perfumes, valuable drugs, and a minor host of other substances. The gas "waste" in Great Britain and the Continent is now worth five millions a year. Europe could afford to pay for a big war every year with the gas waste. The "waste" in paper manufacture was similarly a matter of legislation a few years ago; now it is nearly all recovered and turned to economical advantage. The districts of St. Helens, in Lancashire, and the banks of the Lyne are crowded with chemical works, all engaged in manufacturing something useful and profitable out of "waste."

Sometimes it is not merely an article in the wrong place that is wasted from being a nuisance and converted into something useful, but a something which for generations has had no value is suddenly endowed by the ingenuity of modern discovery into a variety of utilitarian objects. For thousands of years asbestos has had no value. A few oriental monarchs amused their surprised guests by having napkins woven out of its fibre, which were thrown into the fire to be cleaned. Its Greek name expresses this inconsumability. But within the last 20 years asbestos has assumed a wide usefulness, and the finder of a new seam of asbestos would do better than the discoverer of a gold mine. Most of us are only acquainted with this mineral in connection with our modern gas stoves, but it has a host of applications besides. Lamp wicks, boiler packing, incombustible felt ropes, mill board, stoppers for our huge guns, time fuses

charge preservers for torpedo and dynamite shells, coating for ironclads, cloth for balloons, safety coverings for roofs and floors (commonly adopted in America), curtains and other properties for theatres, movable shields for preventing the advance of fire, clothing for firemen, filters, pipe joints, furnace linings, insulator lamp shades, tobacco pipes, soles and linings for boots and shoes, soldering blocks for watch-makers, moulds for type founders, each and all of these multitudinous objects and operations are administered to by asbestos. The latest are an asbestos paper and compound tobacco asbestos mixture for cigarettes. Artificial asbestos can be made out of useless clay by steam-blowing the molten mass into thin hairs, resembling floss silk. Asbestos, natural and artificial, is capable of still further application, and perhaps the artificial kind is as yet only in its infancy. Waste only exists where ignorance exists. "For nought so vile upon the earth doth live, but to the earth some special good doth give."—*Australasian*.

AN INSECT ENEMY.—"E. B.," writes from Matara:—"I send you under separate cover two worms. I am very much interested in knowing what they are. These worms especially the younger ones of the same species I believe; but green in colour are destroying my plants. I tried many remedies without success." Our entomological referee reports:—"Caterpillars of a common brown moth; one moth was found in the match-box, but so much damaged, that it was impossible to identify it."

THE CUT FLOWER TRADE IN FRANCE.—Three hundred and twenty-three tons of cut flowers, says the *Liverpool Mercury*, sounds an enormous amount, and so, without doubt, it is. Yet this was the weight of the quantity of cut flowers packed and sent out during the four months from November to February from Cannes alone. Their value would be estimated at £65,268. The trade is said to be increasing at an almost incredible rate, and within the past eighteen months no fewer than fifty-three new establishments have been started for the cultivation of flowers. From Nice, the report is that the flower trade has been much depressed owing to the severe frost of the winter. It is said, however, to have yielded—the whole district—15,000,000 francs during last year.—*Gardeners' Chronicle*.

THE JAPAN TEA EXPORT COMPANY.—The *Japan Weekly Mail* of 11th July says:—

It seems probable that the grant of two hundred thousand *yen*, made by the Department of Agriculture and Commerce to the Tea Company—the grant about which so much has been said in the press and the Diet—will never become available for the Company's purposes. The affair has lingered interminably, and statements are also in circulation to the effect that the terms on which the subsidy was given have been violated by the projectors. The *Shogyo Shimpo* says that, the matter having been brought to the Cabinet's notice, the latter decided on the 3rd instant, to re-pass into the Treasury the sum of two hundred thousand *yen*, which has hitherto been lying in a bank, for the purpose of being transferred to the Company so soon as the latter should have qualified to receive it. The *Mail* of 18th July has the following:—

The rumour that the Minister of Agriculture and Commerce had determined to recall the grant of two hundred thousand *yen* made to the *Seicha Kaisha* or Tea-manufacturing Company, was well founded. On the 10th instant a notification was issued, over the signature of Mr. Mutsu, in the following terms:—"In-as-much as the Japan Tea-manufacturing Company has not fulfilled the conditions originally fixed by its charter, the subsidy of two hundred thousand *yen* granted to it is hereby recalled, and the said sum must be returned within thirty days from the present date."

The Directors of the Tea Export Company intend to raise an action against Mr. Mutsu, Minister of State for Agriculture and Commerce, on the ground that his administrative action in regard to the subsidy, granted by the Government to the company, is illegal.

THE APPROACHING REVOLUTION IN TEA FIRING.

A TEMPERATURE RECOMMENDED LOWER BY NEARLY 100° THAN THAT GENERALLY EMPLOYED!

We have had a visit from Mr. Davidson of "Sirocco" fame,—the patentee and manufacturer of many hundreds of updraught and downdraught tea driers, which are so largely in use in India and Ceylon. Mr. Davidson has been connected with tea, as planter, buyer and seller, and, latterly, in the useful and important capacity of machinist, since 1864. He knows as much about the culture and manufacture of tea as any men living, perhaps; but like all truly scientific men he has not only not been ashamed of ever learning, but has had the courage fairly and fully to face and *unlearn* what seemed fixed principles in the pursuit. Until recently Mr. Davidson firmly believed in and taught the doctrine that a temperature of 240 degrees was the best in tea drying. A series of most interesting experiments in the laboratory and with his downdraught driers has convinced him that he has been mistaken; and while on estates in India he has doubled the average value of teas by preparing them on the new principle of drying at so low a temperature as 130°. This, he explains, means a temperature of 150° in the heat of the sirocco, the evaporation of moisture from the leaf keeping it down to 130°. Before getting so dry as to rise above that temperature, Mr. Davidson advises that the tea should, near the close of the drying process, be removed to and finished off in a separate sirocco, the heat of which should be only 130°. To our question whether this would not greatly extend the time required to dry quantities of tea, he replied that such an objection was obviated by power applied to the downdraught which would cause the air to pass through the tea at the rate of eighty miles an hour. The philosophy of the reformed process Mr. Davidson explains to be the preservation by the use of the reduced temperature of the volatile oil, on which, more than any other constituent, the fine flavour of tea depends. At the high temperatures of 240 deg. and even more formerly used, this oil was dissipated, and what Mr. Davidson deems the very poor substitute which is technically called "maltiness" took its place. We quite understood Mr. Davidson to add that the carrying on of the curing process at a low temperature would also put an end to the persistently repeated complaints of the non-keeping qualities of Ceylon tea. He ascertained in the course of his investigations that the better keeping qualities of the weaker China teas is due to the really low temperature at which they are fired.—All this is not only exceedingly interesting but very important, and it is a fortunate coincidence that Mr. Davidson should land at Colombo during the festivities which will draw so many leading planters to Colombo. To these Mr. Davidson can fully explain and with them he can discuss the principles on which the new process, which really amounts to a revolution in tea drying, are founded, with the various details of power, exhaust fans, &c. After a short time in Colombo (when appointments to meet him can be made through Messrs. Mackwood & Co.) Mr. Davidson, to whom Ceylon is new (he having only touched at Galle a score of years ago), means to take a tour through the tea estates, the results of

which may be profitable to him in giving him additional information and leading to new connections, and fresh improvement in his machinery, while the information which he as scientist and machinist has to impart cannot but be advantageous to the planters and to their fast advancing enterprise, which, at this crisis in its history, needs all the help that experience, scientific research and improved appliances can afford. We have had abundant proof that we have greatly underrated the producing powers of our soil and climate; and while quantity is so rapidly increasing, it is of the utmost importance that quality should be kept up to the highest possible point. This is what Mr. Davidson is confident can be done by the adoption of the new method of drying the leaf, of which we have given the main principles, and which Mr. Davidson is ready and willing to explain in full detail.

In justice to Mr. Jackson we feel bound to recall the fact that he also has been addressing himself to the solution of the problem of drying tea at a lower temperature than has been usual. In the description of his new machine, the "Britannia," it is stated:—

At the present time, approximately two-thirds of the tea exported from Ceylon and India is being dried at a temperature of from 240 to 300 degrees. This high temperature is resorted to, simply to get the work out of the machines, the result being that brokers and dealers, have from time to time, and are at the present moment, commenting on teas being high-fired, scorched, and that they will not keep. In designing and experimenting with the Britannia Dryers, which has occupied Mr. Jackson's time for nearly two years, he has steadily kept in view the necessity of improving the tea, especially its keeping qualities, that the temperature at which the Britannia Dryers should work, must not be higher than the tea will bear even if left in the machine for an undue time, and Planters will at once realize the great importance of this. It will also be patent to all, that working at the reduced temperature is easy and practically obviates destruction of the air heating stove, which is built on an improved and durable principle, and should require no repairs for many years. Most Planters will be able to appreciate the principle under which Tea Rollers work, i.e. a charge of leaf is put in the machine, pressure is applied, and the machine is left to do the rest. The Britannia Dryers practically do the same:—The leaf is fed into the trays forming the endless web, fuel is put in the furnace, and the machines do the rest. This at once removes all tedious attention required in Dryers using trays, and other drying surfaces requiring manipulation by hand, and all conversant with mechanism must know that automatic machines of all kinds are the best. The trays forming the endless web in the Britannia, are individually pivoted on the chains; they follow each other closely but do not come in contact with each other, or with any part of the machine whatever, consequently there can be no wear and tear on them. The Britannia Dryers have the nice arrangement, that the endless web comes continuously out of the drying chamber, which not only permits constant examination, but allowing the web to cool down, obviates any risk of scorching the tea by contact.

The fan of the Dryer is a very powerful one, is perfectly balanced, and so strongly built, that it is capable of having as much higher velocity imparted to it without danger. The bearing also on the self-adjusting principle, and a novel and neat arrangement prevents waste oil escaping at the ends of the bearing. The saving in first cost of one of these machines, in labour to work it, in space occupied, in fuel, &c., is great when compared with a number of small machines, but this is a secondary matter when compared with the far more important consideration of obtaining nice flavored, good keeping uniformly dried Tea.

PLANTING PROGRESS IN THE MATALE DISTRICT.

(From Mr. G. S. Sæton's Administration Report for 1890.)

Mr. Hugh Fraser, of Bandarapola estate, has kindly supplied me with the following information:—
Tea is prospering, and is being extended in Matala North, Matala East, Bandarapola, Uktuwela, Laggala, and the Matala East end of Kelebokka. From 500 to 600 acres were added to the previous area in tea.

More expensive machinery, and more of it, is required for tea than for coffee; and it is pleasing, after one gets over the idea of the cost, to see the successful efforts made by engineers to provide tea planters with such suitable and good machinery.

Cotton and anatto have had a check in popular esteem and have not been much extended. Moisture and insects are the bane of the one, and low prices, consequent on limited demand, of the other. It is belived cotton would do better in a drier climate.

The south-west monsoon was comparatively a failure in the matter of rain, consequently the season was an unfavourable one for tobacco, and the large clearings in Matala are below expectations. This enterprise deserves better results and these I hope await further efforts.

Cacao continues to improve in favour, and there is the encouraging fact that prices have kept up. Small patches of native plantations of this product are to be seen here and there at long intervals in the village, but a great deal more might be done in this direction, and further effort impressed on the villagers. Moormen traders are at present perambulating the district, paying 50 cents a pound, equal to R56 a cwt. or cacao cured in a very primitive fashion.

The European cultivation of cacao in various portions of Matala, as for instance Wariapola, Mr. Barber's Grove estate, Yatawatta, Sylvaakoda, and many others, are equal to anything to be seen elsewhere in the Island.

Cardamoms do well in suitable situations at the higher elevations, but unfortunately there is not much suitable land left unopened, so the extension of this product is scarcely possible. The Mysore variety does better than the Malabar. The lowland's do not seem to be suitable for the successful cultivation of either variety.

In the neighbourhood of Matala town the rainfall for 1890 was:—January 1st to June 30th, 28.89 in.; July 1st to December 31st, 27.75 in.; making 56.64 in. for the year; more than 20 in. less than the usual fall, the deficiency being spread over the year, but more marked in October, November and December.

In a portion of Laggala, Matala East, 172 in. of rain fell during the year, and this, although ample for all useful purposes, was also short of the average fall.

An experiment on a limited scale has been made in the district with Coorg coffee, and the result of this clearing will doubtless be watched with interest.

INDIAN AND CEYLON TEA IN AUSTRALIA AND NEW ZEALAND.

Elsewhere we quote from the Melbourne *Argus* a review of the tea trade in the Australian colonies during the season ending 30th June of this year. Our readers will observe that in the important markets of the Southern lands Indian and Ceylon teas are rapidly superseding the China product, the sway of which until about ten years ago was undisputed and believed to be indisputable. The quantity of tea received from Foochow in the twelve months was 15½ million of pounds, against 21 and 24 millions during the two preceding years. The decrease in three years was, therefore, no less than 8½ millions of pounds, while the quality of some of the China tea received was so bad that the Aus-

toms authorities refused to admit it. Meantime Indian and especially Ceylon tea had continued to gain favour, the only objection offered being the non-keeping quality of the latter, an objection which we trust fixing at a low temperature will remove. The shipments from India and Ceylon to Australia in the twelve months are stated in figures the aggregate of which very nearly compensates for the deficiency in China, thus:—

From India,	4,800,000 lb.
" Ceylon	2,900,000 "
			Total.. 7,700,000 lb.

The sudden spring upwards in last season is remarkable. It is distinctly stated that the public taste has taken rapidly to the more flavoured and softer teas of Ceylon, and that it only requires time to educate the public taste so as to secure a good demand for choice teas from both India and Ceylon. In Australia as in Britain our teas are taken in large proportion to our total production, and if only the United States and Russian markets could be conquered, as those of Australia have been, we should feel less concerned about the future and the danger of over-production and unremunerative prices than we now do. We trust that at least a million, if not two millions, of ounce packets of Ceylon tea will be distributed gratuitously, in addition to what may be sold at the great Chicago Exhibition.

THE EXPORT OF INDIAN TEA AS COMPARED IN VALUE WITH OTHER STAPLE EXPORTS, AND WITH A FEW LEADING IMPORTS.

Mr. J. E. O'Connor, the Under Secretary in the Indian Department of Finance and Commerce, whose able annual reviews of the trade of our great Eastern empire are widely known and as widely appreciated, has issued in advance the first chapter of the review of the imports and exports and navigation for the year ended March 31st, 1891. We quote the remarks devoted to Indian tea, which we preface by a notice of figures showing the position this product occupies amongst the leading staple exports of India. Tea are enumerated amongst which tea occupies seventh place, with a value, in 10-rupee pounds, represented by the symbol Rx, of Rx5,219,000. As exchange was high during a large portion of the year, the equivalent in sterling may have been not far below four millions of pounds. Mr. O'Connor separates "cotton, manufactured," from "cotton, raw," and so with jute, but the magnitude of the two great fibres in the trade of India is better shown by giving the aggregate values of raw and manufactured. This we do in each case, altering the classification accordingly. The results are —

(1) Cotton	{ Raw	Rx16,502,000	} Rx24,204,000
	{ Manufactured ..	7,702,000	
(2) Grain and pulse	19,539,000
(3) Jute	{ Raw	Rx7,602,000	} 10,084,000
	{ Manufactured ..	2,482,000	
(4) Seeds	9,343,000
(5) Opium	9,261,000
(6) Tea	5,219,000
(7) Hides and Skins	4,695,000
(8) Indigo	3,073,000

Considering the high position occupied by indigo for a century before tea was even dreamed of, it is striking to notice how the new staple has taken rank before the old, and as food is of more value to the human race than the most beautiful of

dyes or the most potent of drugs, it requires no prophetic powers to anticipate the early period when opium also, which has decreased very considerably in quantity and value, will take rank below tea. That is, if over-production and the now formidable competition of Ceylon do not impede the advance of tea production in continental India. The large figure for grain and pulse, is, Mr. O'Connor explains, due to an exceptionally large export of rice from Lower Burma, in consequence of the failure of the rice crop in Japan. Burmah was drawn upon not only to supply places where Japan rice had previously gone, but to meet the wants of Japan itself. The results are the figure of nearly 20 millions of Rx. pounds as the value of food grains exported, and Rx200,000 collected as duty on rice, that grain, from the necessities of the revenue, being the only article amongst exports which is taxed. The statesmen and financiers of India feel the anomaly of this additional tax on an article of food which has already paid land tax, and they would gladly abolish it, if they could safely do so. But the Government must be carried on and the *Pax Britannica* preserved. All the imports liable to duty in a tariff as free trade as that of Britain gave a sum considerably below the export duty on rice, the total levied on liquors, salt, opium, petroleum, and arms and ammunition being only Rx774,000,—the aggregate customs duties being thus Rx1,674,000. Petroleum was subjected to duty on the same principles as those applied to rice: the necessities of Government and the ease with which appreciable revenue could be levied on an article of exceptional magnitude, which it was felt could fairly bear the burden. The consumption of this mineral oil in India is enormous, and the time in which it is imported are in use by the people for the most varied purposes, from Cape Comorin to the border of Afghanistan. Mr. O'Connor states:—

Mineral oil has increased, and the vigorous Russian competition in this article with the United States is indicated by the fact that, though importations from Russia commenced only three or four years ago, last year 38 per cent of the total imports were from that country. It is perhaps not rash to anticipate that before long this proportion will be doubled. The oil is good, and as freights from the Black Sea are lower than freights from the United States, it can be sold more cheaply than American oil, and cheapness is what the native wants.

And if Russia is ousting an American product in the commerce of India, Germany is to a more serious extent superseding France. The combined effects of the bounties on beet root sugar and the extension of German steam navigation to India are, that in the one article of sugar, the imports into India had risen from a value of Rx550,000 average in the period 1874-75 to 1879-90, more than an equivalent quantity being exported, to Rx1,840,000 in 1886-87 to 1890-91, in which latter period the export was only Rx1,058,000. India, therefore, the original home, probably, of the sugarcane, and in which it ought specially to flourish, has her markets overwhelmed with refined beet sugar from Germany, the result of sugar bounties and steam subsidise; while the illegitimate attempts of the United States authorities artificially to raise the value of silver, have seriously and in many cases disastrously disturbed the money markets and commerce of the world. The Indian Government has benefited largely by the higher exchange, the increased value of the rupee, and especially the extensive investments in rupee paper. But individuals have been injured and speculation, both in silver and in gold has been wild and in many cases ruinous. But we must devote more detailed attention on

a future occasion to Mr. O'Connor's able review of the almost anarchical position of exchange and the value of the precious metals, with the effects on commerce and industry, during 1890.

The notice of Indian tea exports is as follows:—

The export of tea has continued on an increasing scale over 107 million pounds having been exported; but the increase (about 8 per cent) has not been so great as in former years, and it would seem that the active competition of Ceylon—now that China has been beaten in the race—is beginning to tell. The United Kingdom imported in 1890 about 10½ million pounds from India, while the imports of China tea had fallen to less than 7½ million pounds. But from Ceylon, on the other hand, there were imported about 4½ million pounds, a remarkably large quantity considering the recent commencement of tea cultivation in that island. Ceylon has certainly great advantages in its greater nearness to England and to Australia than Calcutta and the consequent smaller freight that has to be paid, in the close proximity of the tea gardens to the port of shipment, in the abundant and cheap labour supplied to it from the adjacent ports of Southern India, in climatic conditions, and in the excellent quality of most of the tea produce. The planters of the island have also been able to profit by all the experience gained in India and to avoid the mistakes that were made here in the earlier days of the enterprise. It may be well for tea planters in India to recognise distinctly that the pushing competition of Ceylon must inevitably bring about in the near future a permanent fall in price unless we can largely widen our markets, the two largest markets in America and Australia being still practically held against us by Japan and China. What Mr. O'Connor says of the American market (including only the United States under this term, for the case of Canada is more hopeful) is quite true; but the review of the Australian tea market which we give elsewhere shows how rapidly Indian and Ceylon are gaining on China. Nearly 5,000,000 lb. of Indian tea and about half that quantity of the Ceylon product had been imported into Australia in the season, and these teas were fast advancing in favour.—A change this since 1880-81, when the representatives of India and Ceylon at the Melbourne Exhibition were subjected to virulent abuse for daring to speak or write in favour of products which threatened to disturb existing and very profitable monopolies in the import and sale of Chinese, largely of the "post and rail" quality which was thought good enough for "the bush."

REVIEW OF THE AUSTRALASIAN TEA SEASON 1890-1.

(From the Melbourne *Argus*, July 24th.)

In following our usual custom of reviewing the tea season of the past 12 months, we find that important changes have taken place—changes that affect the various ports of shipment, the local mode of distribution, and the financial results.

CHINA TEA.

Under this heading we find Foochow sending to Australia and New Zealand only 15½ million pounds, against 21 and 24 millions during the two preceding years; Hankow and Shanghai sending almost nothing; and Hong Kong and Canton rather an increasing quantity—principally shown in a much heavier weight of Canton koolos for blenders and a diminution of low-grade Tayshan congous. With the shipments from Foochow there has been, besides a marked reduction in the quantity sent forward, a far greater change in the relative proportions of the usual grades. The stronger demand from London diverted all the clean, sweet, comen congous, leaving our requirements for "price" leaf to be badly filled with low, coarse

common, old tea—much of it many seasons old. The peculiar earthy flavour of this description attracted the attention of our Onston-house tea experts, who by their action in sending the first shipments back to the original port of shipment, caused the transshipment of the bulk of the shipments following, with the result that the adjoining colonies accepted leaf unsuitable for Melbourne to the extent of about 500,000lb. The net benefit to this colony was that, on the whole a somewhat purer tea reached the public at the expense of a diversion of trade to our neighbours. But if the rejected tea is good enough for Australasia at large, why deprive Victorians of it? If however, the Victorian Customs officers were right it is to be regretted that the other colonies admitted it.

The inferior value shown at the commencement of the season for all low grade teas naturally reduced the export from Foochow, and so afterwards enabled a fairly remunerative trade to be done in them, but the absence of London demand for all better qualities, had such a depressing effect that quantities of these grades out of all proportion to requirements were sent forward because they were relatively cheap. The result has been that except within the first month after the opening sales—when fancy prices were paid for finest congenous—it has been impossible for shippers to cover cost above 8½d; and in some instances, towards the close of the season, heavy losses have had to be faced upon all good medium to fine teas. The excellent value thus obtained has certainly been of great assistance to the blending trade, enabling them to more easily pay the higher prices ruling for the Indian, Ceylon, and scented requirements of their trade. Against the unfavourable results to importers of good quality congenous, caused simply by over-supply, we find fancy laces, such as scented pekoes and capers, and also kaisow buds, commanding handsome profits, through shortage in supply, a shortage caused by the ruinous prices paid during the one or two preceding years curtailing manufacture.

INDIAN TEA.

From Calcutta we find a large increase in shipments, the respective figures being 4,800,000lb for the past season against 3,600,000lb and 2,880,000lb the two preceding years respectively. Large as this increase has been, it does not fairly indicate the increase in public favour of these full teas, because the bulk of our demand at present is confined to plain, strong, clean kinds, and those have also been so freely taken for London at high rates that our limited selection commanded almost equal prices to fair pekoes. To more clearly indicate the strength of the demand, we find that for over eight months of the year clean souchongs were selling within ¼d per pound of strong thick pekoes, whereas, had we had a quiet market without disturbance in the lower grades, probably the extra trade in them would have added another 1,000,000lb. to our consumption. With a strong London demand for low cost leaf and with our local market over-supplied in good pekoes and fine teas, it would have been unreasonable to have expected this trade to have been satisfactory to shippers, and it is surprising that large quantities were taken at and over 9½d per pound, considering that the colonial markets were mainly created by equally valuable teas at 1d to 1½d per lb. less in souchongs and pekoo souchongs, and by far smaller quantities of pekoes and fine teas.

CEYLON TEA.

From Colombo we have even a more rapid development of the exportations of tea to the colonies to chronicle, the shipments running up to 2,500,000lb. rs against 1,500,000 lb. and 940,000 lb. for the two preceding years respectively. The public taste has certainly taken rapidly to the more flavoury and softer teas of Ceylon, and there can be no doubt that not only China, but also India, has much to lose from the competition from Ceylon. The well-cured Ceylon teas are certainly most attractive, being remarkably flavoury, with good strength. Ceylon teas, however, have one serious disadvantage, and that appears to be their inferior keeping qualities; and, judging from the present year's receipts, this trade is certainly "the

jam tart trade" in tea—they are all better sold fresh than stale and flat, which, in many instances, from inferior manufacture, they soon become. There is, however, a somewhat better demand for choice Ceylon pekoes than for Indian pekoes, and it only requires time to educate the public taste for the demand to be good for choice teas from both Calcutta and Colombo. For this trade it is somewhat difficult to gauge the financial result, so much being sent upon garden account or upon speculative consignment that one becomes quite accustomed to disastrous losses upon invoice cost; but as far as we can gather the trade, as a whole, has yielded better results than that in India, though in many instances very imperfectly cured leaf and, poor (and except breaks have been sent to this market because London did not take them freely.

DISTRIBUTION.

The marked change shown above in the demand for Indian and Ceylon teas as against China sorts has necessarily led to extensive changes in the distributing business, compelling distributors to add blending and packing to their existing tea departments. So rapidly has this trade increased, that even at this early stage it is not uncommon to hear salesmen complaining about the small volume of sales passing in "straight" teas. The complaints of distributors were both loud and deep upon discovery that the official returns of stocks in bond were understated, more especially as only 12 months since they were issued as correct, this error leading to unprofitable speculation based upon the apparent shortness of supplies.

STATISTICS.

We are indebted to the courtesy of the secretary of Customs for the following particulars (for Victoria only) regarding the imports, exports and home consumption of tea for the season July 1st, 1890, to June 30th, 1891. Imports were as follows:—

From—	Duty Paid,		Total.
	Ex Ship.	Warc-housd.	
	Lb.	Lb.	Lb.
Foochow ...	122,969	8,972,350	9,095,319
Hong Kong ...	127,678	562,432	690,120
Calcutta ...	43,074	2,826,231	2,869,305
Colombo ...	45,763	1,207,578	1,253,341
Other colonies, &c.	55,120	579,423	634,543
Total ...	394,604	14,088,024	14,482,628

Quarter by quarter the imports were as follows:—

	Lb.
September quarter, 1890 ...	5,480,427
December quarter, 1890 ...	5,280,643
March quarter, 1891 ...	2,950,566
June quarter, 1891 ...	771,052

NOTES ON PRODUCE AND FINANCE.

NEW MARKETS FOR INDIAN TEA.—Our readers will be glad to learn that a really bona fide attempt is about to be made, under the auspices of influential and representative leaders of the Indian Tea Industry, to consolidate and place on a firm footing proposals for opening up new markets for Indian tea. Various laudable, but at the same time more or less isolated efforts have, during the past eight or ten years, been made to accomplish this end. But there has unfortunately been a great lack of continuity, an absence of that "shoulder-to-shoulder" movement, which is required, a want of the proverbial unity of purpose, which constitutes strength, and last but not least a dearth of funds sufficient to ensure sustained action. These faults of the past, it is confidently hoped, will no longer exist, and, as the partly-shattered, but still living, remains of the movement initiated at the Healthies, at the Indian and Colonial Exhibition, by the Associated Planters (American scheme), and at the Paris Exhibition, a solid and enduring structure is, we believe, arising. A small company has been formed, which it is proposed should commence its operation

at first quietly, but which will be capable of expansion and extension in due time. Its first object will be to take up the work which has been going on in France since the Exhibition of 1889. It will probably next turn its attention to America, and endeavour to effect a foothold at the forthcoming Chicago Exhibition. Its future developments will depend on circumstances. The fact remains, however, that if properly supported by the Indian tea industry, a nucleus will be formed for extension in almost any direction, and there will be an organization ready, with funds at its disposal, to take advantage of any and every favourable opening which may present itself for extending and pushing the use of Indian tea all over the world. The planting interest, who is not a great deal of money wanted, and, if every company and every individual possessing an interest in tea growing will give his quota, the actual call on each will amount to a mere trifle. Particulars will shortly be made public, but we sound this note in advance, in order to prepare our numerous readers and invite them to be ready to play their part when the time comes. The prospectus of the Palais Indian Tea Houses Company we give elsewhere.

A TRADE OPINION.—Commenting on last week's sales of Indian and Ceylon tea, the *Produce Markets' Review* says:—With a continued good supply of new Indian tea at moderate prices more business has been transacted. The quality of the recent import is not up to the average of the earlier arrivals, but the decline in value has stimulated the enquiry for the lower grades. As these have now fallen to a point at which they can be freely used, and compare favourably with similar descriptions of Ceylon growths, an increased consumption may be looked for, with a further improved enquiry generally. The finer sorts are in unusually small supply, particularly Broken Pekoes with good appearance, consequently the market continues extremely firm, and probably will remain so until a more liberal quantity of the better class new tea is offering. Recent telegrams from Calcutta report the quality of the tea from Assam as good; if this is confirmed an arrival here it will be sure to meet with a good reception, and will sell readily. The quantity of Ceylon teas brought forward this week has been larger than that during the two preceding ones, but not so large, however, as was generally expected. Prices have, on the whole, shown little fluctuation, for any tendency towards lower rates on Tuesday was fully compensated for by a decidedly stronger feeling again on Thursday. The absence of quality is still lamentably noticeable, and extravagant prices are in consequence being paid for a few Broken, which have no claim whatever to be considered as fine teas.

SPRING VALLEY COFFEE COMPANY, LIMITED.

DIRECTORS.—John Brown, Esq. (Managing Director), Edward Conder, Esq., Leon Panin, Esq., Henry Hart Potts, Esq.

REPORT to be presented to the Twenty-sixth Ordinary General Meeting of the Company to be held at No. 5, Dowgate Hill, London, on Wednesday, the 29th day of July, 1891, at 12-30 o'clock p. m.

The following Annual Accounts are now presented to Shareholders, viz:—Profit and Loss Account for Crop 1889-90. Balance Sheet made up to 31st May, 1891.

CROP 1889-90.

In last year's report, shareholders were informed that the coffee crop of the above season was unsatisfactory, and it will be seen that the actual weight sold in London amounted to only 805 cwt. as against an original estimate of 1,200 cwt. This small crop, inclusive of inferior coffee sold in Ceylon, realised £1,345 7s 2d, the average selling price in London being

10s 4d, as compared with 9s 9d per cwt. obtained for crop 1888-89.

The yield of tea on Spring Valley amounted to 132,000 lb., the estimate in last Report being 113,000 lb., and this, together with 38,140 lb., bought from neighbouring estates and manufactured at Spring Valley, sold for £7,966 15s 2d, or an average of 11½d per lb., the average selling price last year being 10½d per lb.

Oolanakande Estate produced 18,477 lb. of tea, including 5,700 lb. made from bought leaf, which realised £748 2s 2d, and brought an average of 9½ per lb., as against 8½d per lb. last year.

Cinchona bark to the extent of 30,236 lb. was also sold for £313 2s 9d, the average selling price being 2½d per lb. or 1d per lb. under last year's average.

The total proceeds from the sale of produce amounted to £13,403 7s 8d, to which has to be added £120 14s 8d, derived from interest, making the total receipts £13,524 1s 11d.

The total expenditure in Ceylon and London, after allowing for profit on exchange, amounted to £13,541 6s 10d and deducting from this the amount of receipts, there remains a loss of £17 4s 11d on the year's working.

It will be remembered that a considerable sum, £2,475 17s 3d, was brought forward from last year, as the Directors had reason to anticipate some such result as the above, so that the amount now standing at the credit of Profit and Loss is therefore £2,453 12s 4d.

On the 12th January last, an interim dividend of 1½ per cent was paid on the capital of the Company, and the Directors recommend that a further dividend at the same rate be now declared, making 3 per cent for the year, and leaving £38 12s 4d to be carried forward to next account.

CROP 1890-91.

It is satisfactory to be able to report that the outlook for this season is very good. The coffee crop is expected to total 3,400 cwt. This marked improvement is due to the comparative absence of leaf disease and green bug, the pests which have for so long been persecuting the coffee bush. The nature of these pests is, however, so peculiar that it is impossible to say to what extent this immunity can be relied upon for any length of time. The weather has, no doubt, had much to do with checking the influence of these pests on the coffee bush during the present season, and although it is hoped that the diseases may only continue in a mitigated form, still, in view of past experience, it would rash to count too hopefully on these pests not putting themselves strongly in evidence again as we have had similar disappointments in the last few years. On the other hand the coffee is reported to be looking well for next season. There are 872 acres still remaining under coffee on Spring Valley, and it is not intended in the meantime to replace any of this area with tea.

The tea on Spring Valley continues to grow well and steadily improve in yield, and the crop for the above season will probably be about 160,000 lb.

The prices ruling in the tea market just now are not satisfactory.

The area under tea is as follows:—

Tea.	acres.
Planted Nov./Dec. 1884, on Spring Valley	271
" May, 1885, on Oolanakande	143
" Nov./Dec. 1885, on Spring Valley	230
" May, 1886, on Oolanakande	7
" Nov./Dec. 1888, on Spring Valley	20
" Nov./Dec. 1890, on Spring Valley	96
Total area under tea	767

The price of silver ruled high during four months of the current season, so that it is not expected that the profit of Exchange will be so large as last year.

Mr. Edward Conder, a Member of the Board, retires on this occasion, and being eligible, offers himself for re-election.

Messrs. Deloitte, Dover, Griffiths & Co., the Auditors, also offer themselves for re-election. By order:

J. ALCO ROBERTS, Secretary.

July 20th, 1891.

OUVAH COFFEE COMPANY, LIMITED.

Capital £100,000, in 10,000 shares of £10 each.
DIRECTORS.

John Brown, Esq., Managing Director.
H. H. Potts, Esq., L. Famin, Esq., Edward Couder, Esq.

REPORT

To be presented to the Twenty-eighth Ordinary General meeting of the Company, to be held at No. 5, Dowgate Hill, London, on Wednesday, the 29th day of July, 1891, at 1 o'clock p. m.

The following Annual Accounts are now presented to Shareholders, viz. :—Profit and Loss Account for crop 1890-91, Balance Sheet made up to 31st May, 1891.

CROP 1889-90.

In the Directors' last Report the coffee crop of the above season was estimated at 1,400 cwt., and it will be seen that the actual weight sold in London amounted to 1,460 cwt. 2 qrs. 5 lb.

The total proceeds, inclusive of a small quantity sold in Ceylon, amounted to £7,719 7s 10d., giving an average of 102s 5d per cwt., against an average of 96s obtained for the previous crop.

The crop of tea was estimated at 250,000 lb. and the actual weight sold from the Company's own estates was 213,241 lb. Besides this 219,812 lb. of tea manufactured from leaf bought from neighbouring estates were sold.

The total value of all tea sold was £20,126 14s 1d, or an average of 105d per lb. as compared with 11d for the previous season.

The weight of cinchona bark sold was 45,563 lb., and the value £753 14s 9d, or 3 1/2 p per lb. against the former year's average of 4 1/2 p per lb.

Cocoa weighing 57 cwt. 1 qr. 23 lb. realised £253 12s 9d, the average selling price being 88s 3d per cwt. against 81s for the former year's crop.

It will thus be seen that the total value of all produce sold amounted to £29,233 9s 5 1/2 d.

The total Expenditure for the year in Ceylon and London, after allowing for Profit on Exchange, amounted to £24,025 12s 1d, and deducting this from the value of the Produce, a Profit is shown on the season's working of £1,598 5s 1d. To this has to be added the balance of £68 12s 8d, brought forward from last year, giving a total of £1,666 17s 9d at the credit of Profit and Loss Account.

An interim dividend of 1 1/2 per cent. on the capital of the Company was paid on 12th January last, which absorbed £1,500 of the above named sum, and the Directors now recommend that £2,500 be applied to the payment of a further dividend of 2 1/2 per cent. making 4 per cent. for the year, and that the sum of £614 9s 10d be written off Machinery Account, reducing it to £600, thus leaving £52 7s 11d at the credit of Profit and Loss to be carried forward to next account.

CROP 1890-91.

The Directors are able to report a favourable outlook for this season, and if the market prices of tea and coffee are fairly maintained, they have every hope of paying an increased dividend for the ensuing year.

The pests of green bug and leaf disease, which of late years have done so great injury to the coffee bush, have for the past season been somewhat in abeyance, and have thus allowed a fair crop to mature, the coffee crop for the season being now estimated at 2,500 cwt. The coffee on the estates is reported to be looking well for the next crop, but owing to the capricious nature of the pests referred to, it is impossible to say how long this imperative immunity from disease may continue or whether it is only due to favourable climatic influences. The area still under coffee is 567 acres, and it is not intended in the meantime to replace any of this coffee with tea.

All the tea on the Company's estates is growing and yielding well, and the estimated crop for the current season is 280,000 lb. which it is thought will be secured. At the present time, the prices ruling for tea are not satisfactory.

By the end of the year the Directors hope to have the Company's three Tea Factories fully equipped with machinery, &c.

The area now under tea is as follows:—

	TEA.	
Planted November/December	1888	9 acres.
"	1884	347 "
"	1885	448 "
"	1886	27 "
"	1887	17 "
"	1888	67 "
"	1889	12 "
"	1890	258 "

Total area under tea ... 1185 acres.

As the price of silver ruled high during four months of the current season, the profit on Exchange will not be so large as during season 1889-90.

Mr. H. H. Potts, a member of the Board, retires on this occasion, and, being eligible, offers himself for re-election.

Messrs. Deloitte, Deyer, Griffiths & Co., the Auditors, also offer themselves for re-election.

By order, J. ALCO ROBERTS, Secretary.
July 20th, 1891.

THE EFFECT OF PACKING HEATED TEA IN CHESTS.

According to our last London Letter some misunderstanding appears to have arisen as to a subject of late dealt with in our columns, namely the tendency of tea boxes to absorb damp during their transit homewards in the sweating holds of steamers.

Probably an insufficient distinction was drawn during the discussion of this question between unseasoned woods and those unseasoned by their grain, or from other causes, for use in the making of tea boxes. It may, however, we think be concluded from the arguments formerly put forward that imperfectly seasoned woods are more especially liable to absorb damp during the passage homewards, while those completely seasoned would be free from such a liability. On the face of it it would seem apparent that the first class of these two, that in which dampness was naturally present at the time of weighing on the estate would be less likely to change weight on the journey homewards than the more completely dried and seasoned wood. Such would, it would seem, have already got its full burden of moisture, and would therefore be less likely to change in weight owing to possible taking up of more moisture in a ship's hold. *Per contra* it might perhaps be assumed that a perfectly dry seasoned chest would be likely to readily absorb such dampness as might be present in a vessel's hold. But on giving fuller consideration to all the conditions attending the packing of tea, and to those which constitute a thoroughly seasoned wood, these conclusions may, we think, very probably be reversed.

In the first place, what are the specialities of a perfectly seasoned wood, in the sense that is generally understood? We know perfectly well that seasoning cannot be produced by subjecting the green wood to artificial heat. By such means you may turn out stuff as dry as a chip; but it is not seasoned. Expose it to a damp atmosphere, and the cells of fibres of the wood commence at once to absorb damp and the wet state of material so treated is worse than the first. But the essence of seasoning is the gradual method of its accomplishment. Time is required for the cellular tissue of the timber to contract as its sap and absorbed damp dry out. This fact is so well known to

pianoforte manufactures, that the timber they work up into their instruments is weathered in their yards for many years before use; and only in such a way can material fully reliable for their delicate purpose be obtained. We should hold that the same conditions of necessity apply—though of course in a minor degree—to the seasoning of wood for less important purposes. What we have stated justifies the dictum that mere heat alone—though this may temporarily get rid of dampness—does not exhaust the sap or bring about that gradual closing of the cells which renders a perfectly seasoned wood unattackable by damp. All of us in Ceylon know perfectly well how completely thoroughly seasoned wood worked into pianoforte will remain uninjured, even in a climate so fully charged with moisture as that of Colombo.

These facts prefaced, let us see how the question we have raised may be affected by the conditions present during the packing of tea in chests. We know it to be the case that a great deal of the tea at the time of such packing is in a warm, and very often probably in a relatively hot state. We can readily imagine the effect of placing a bulk of this almost in contact with an imperfectly seasoned wood, the lead lining serving as a good conductor for its heat. The effect, we should think, must be to, to all appearance, dry the wood; but the sap would not be equally ejected, and the cells temporarily constricted, would open and reabsorb damp whenever they came into contact with it in the hold of a vessel. But the chest would have been weighed while there had been a temporary loss of weight due to the packing with the heated tea, and hence we can understand it might have acquired considerably increased weight when tared in the scales of the Home Customs. But wood that has been perfectly seasoned after the manner above pointed out is, by the constricted state of its cells and the binding together of its fibre due to the action of time and the gradual withering out of sap, in a condition of defence against the presence of damp in the atmosphere. It remains, therefore, unchanged by the damp air always more or less present in a steamer's hold, and with the result that its weight, when dealt with by the Home Customs, is very nearly identical with that ascertained respecting it on the estate. It has not, in fact, been affected by the presence in it of heated tea.

The conclusion we drew from this is, that although, as we have said, it would seem natural to suppose that a dry wood (such as is that exposed to thorough and gradual seasoning) would absorb damp more readily than green wood, and so be more liable to a change of weight, the exact reverse is the case under the conditions attending the packing of tea. A fictitious dryness—so to speak—is produced, the tendency of which with unseasoned wood is to render it specially liable to change weight when exposed to damp.

The moral is that all timber used for tea boxes should be thoroughly seasoned.

THE CEYLON TEA FUND.

COMMITTEE MEETING.

Minutes of proceedings of a meeting of the Standing Committee of the Ceylon Tea Fund held at Kandy on Friday, the 14th day of August, at four o'clock in the afternoon.

Present:—Messrs. Giles F. Walker, Chairman, Planters' Association of Ceylon; W. Sandys Thomas, Chairman, Dimbula Association; A. E. Wright, Maskeliya; J. Anderson, Kandy and Matale West; A. G. K. Borron, Kandy; John H. Starey, Kandy; A. T. Karslake, Kandy; W. D. Bosanquet, Kandy;

W. D. Gibbon, Kandy; G. A. Talbot, Kandy and Dimbula; Wm. Forbes Laurie, Kandy and Kurunegala; A. W. Stopford Sackville, Chairman, Maskeliya Association; J. A. Spence, Medamahawura; A. Phillip, Secretary, Planters' Association of Ceylon.

The notice calling the meeting was read.

The minutes of proceedings of a meeting of the Standing Committee of the Ceylon Tea Fund held at Nuwara Eliya on Saturday, the 18th day of June 1891, were taken as read and were confirmed.

Read letter from Messrs. Baker & Hall, Colombo.

Read letter from Messrs. Whittall & Co. intimating that the following estates will subscribe to the "Ceylon Tea Fund" from 1st July:—Dea Ella, Dammeria, Uda Radella, Gleneagles, Oonoongloya, Aberdeen, Hayes, Battawatto, Culsay, Luccombe, and Deanstone.

Read letter from Mr. A. R. Lewis. Resolved:—"That the letter be acknowledged, and that it be pointed out that the Ceylon Tea Company, Limited, under the Patronage of the Planters' Association of Ceylon is not in connection with the Ceylon Tea Fund, and that the Standing Committee trusts that he will reconsider his decision."

Read letter from Messrs. Walker, Sons & Co., Limited. Resolved:—"That in conveying the thanks of the Committee for past liberal subscription to the Tea Fund the Committee hopes that Messrs. Walker, Sons & Co., Limited, will see their way to continuing their subscriptions as heretofore in view of the imperative necessity of steadily persisting in making known and pushing Ceylon tea throughout the world, and the fact that their interests are in large extent affected by the prosperity of the Ceylon tea enterprise."

Read letter from Mr. W. Mackenzie. Resolved:—"That Mr. Mackenzie be thanked for his letter and that he be asked kindly to obtain information as to what the law of Victoria is in reference and bearing on the prosecution indicated."

Read letter from Mr. E. de Frisch, vice Consul for Russia, acknowledging with best thanks a vote of thanks accorded to him, and intimating that he will always be most happy to further the undertakings of the Planters' Association of Ceylon. Resolved:—"That the letter be acknowledged."

GLASGOW INTERNATIONAL EXHIBITION.—Read letters from the Manager, Eastern Produce and Estate Company, Limited, and from Messrs. Aitken, Spence & Co. Resolved:—"That the requests made be complied with."

CEYLON TEA IN GERMANY.—Read letter from the Imperial German Consul enclosing letter from the Secretary of State for Foreign Affairs, Berlin, notifying that His Majesty the Emperor and Her Majesty the Empress Frederick have been graciously pleased to accept the presents of Ceylon tea, and have directed him (the Secretary of State for Foreign Affairs) to transmit to the Planters' Association of Ceylon their Majesties' sincerest thanks for this courteous attention. Resolved:—"That the letter from the Secretary of State for Foreign Affairs, Berlin, be sent to the newspapers for publication."

Read letter from Mr. Sholton Agar. Resolved:—"That Mr. Agar's letter be acknowledged, and that a copy of the rules for the Regulation of Grants of tea for free distribution be sent to him, and that Mr. Agar be requested to ask Mr. Schneider to give a detailed account of his proposed methods of working with particulars as to the duty payable upon tea in Germany and any other matters of interest for the consideration of the Standing Committee."

CEYLON TEA IN FRANCE.—Read letters from the Secretary, the Ceylon Association in London.

Read letter from Mr. H. Whitham with enclosure. Resolved:—"That it be pointed out to the Ceylon Association in London that there was no intention of judging their action in the matter referred to, but rather inviting a reconsideration in the light of the information received by the Standing Committee."

Read letter from Mr. H. Clayton Manisty regarding his scheme for pushing the sale of Ceylon tea in Paris &c. Resolved:—"That the letter be acknowledged

and forwarded to the Ceylon Tea Company, Limited, under the patronage of the Planters' Association of Ceylon."

CEYLON TEA AT THE WORLD'S EXPOSITION AT CHICAGO IN 1893.—Read letters from the Secretary, the Ceylon Association in London.

Read letter from Mr. J. J. Grinton.
Read letter from Messrs. Darley, Butler & Co.
Read letter from Mr. R. J. Farquharson.

CEYLON TEA KIOSK IN COLOMBO.—The Chairman explained the present position of the Kiosk and submitted resolutions passed by the Sub-Committee appointed for the purpose of establishing a Tea Kiosk in Colombo. Resolved:—(I) "That the Ceylon Tea Company, Limited, under the patronage of the Planters' Association of Ceylon be furnished with a copy of the resolutions of the Ceylon Tea Kiosk Sub-Committee of this day's date and be invited to state what guarantees they are prepared to offer to protect the interests of Ceylon tea growers as to the sale of tea in the event an agreement being mutually arrived at. (II) That failing satisfactory arrangements, in the opinion of the Tea Kiosk Sub-Committee, that the Sub-Committee be authorized to call for tenders. (III) That the Chairman be authorized to make such arrangements as he may deem advisable as regards leasing the basement of the Kiosk."

CEYLON TEA IN RUSSIA.—Read letter from the Secretary of the Ceylon Association in London. Resolved:—"That the letter be acknowledged."

NEW ZEALAND AND SOUTH SEAS EXHIBITION.—Submitted letter dated 2nd July to Mr. Wm. Watson, Dunedin, intimating that as the Manager of the Wharf and Warehouse Company, Limited, Colombo, wrote under date the 29th June 1891 that the package named in the shippers' receipt enclosed by him dated 12th March had not arrived it would be advisable to call for explanation from the Steamship Company of New Zealand.

PROSECUTIONS UNDER THE MERCHANDISE MARKS ACT.—Read letters from the Secretary, the Ceylon Association in London, enclosing parcel receipt for a box containing 31 packets of Ceylon blends of tea shipped and inviting attention to the legal position. Resolved:—"That the letters be acknowledged with thanks, but that in the opinion of the Standing Committee of the Tea Fund it is inadvisable at present to take further steps in this matter."

CEYLON TEA IN AUSTRALIA.—Read letter from Mr. S. W. Foulkes, acknowledging draft for £50 sterling, and conveying an expression of grateful appreciation of the liberality of the Association which will stimulate him to further exertions.

CEYLON TEA IN ITALY.—Read letter from Mr. George Vanderspar. Resolved:—"That a specially made ornamental chest containing finest Ceylon tea be forwarded through the Royal Italian Consul for presentation to Her Majesty the Queen of Italy on behalf of the Planters' Association of Ceylon, and that Messrs. Whittall & Co. be asked to have the tea purchased and packed for shipment."

CEYLON TEA IN PERAK (MALAYA).—Submitted suggestions by Mr. O. R. Hanson. Resolved:—"That 40 lb. of Ceylon Pekoe tea made up in 1/2 lb. packets be granted to Mr. Hanson for free distribution in Perak, and that Messrs. Whittall & Co. be asked to purchase the tea."

CEYLON TEA IN WESTERN AUSTRALIA.—Read letter from Mr. W. E. Pye. Resolved:—"That the letter be referred to the Ceylon Tea Company, Limited, under the patronage of the Planters' Association of Ceylon."

FINANCIAL POSITION OF THE TEA FUND.—Submitted statement of account of the Tea Fund as at 30th June 1891 and intimated that since 1st July a further sum of Rs,950-14 had been collected to date. Resolved:—"That the statement of account as at 30th June 1891 be sent to the Newspapers for publication." The Standing Committee of the Tea Fund then adjourned.

A. PHILIP,

Secretary to the Planters' Association of Ceylon.

THE CEYLON TEA FUND ACCOUNT IN ACCOUNTANT WITH A. PHILIP AT 30TH JUNE 1891.

Dr.	R o.
To paid on account Auditor	50 00
To paid on account Book of Proceedings being in payments of half costs of Book of Proceedings of Planters' Association for the year ending 17th February 1890 in terms of resolution of Committee	319 00
To paid on account Ceylon Tea in Russia paid to retire Mr. Wm. Martin Leake's draft per R2,455-08 on account of M. Rogivue's balance Rs,000 voted by the Committee	2,456 56
To paid on account Ceylon Tea in Kiosk	4,618 00
To paid on account Charges, Printing Advertising, &c.	620 50
To paid on account Chicago Exhibition paid into Fixed Deposit being first half-yearly instalments in terms of resolution of Committee	7,500 00
To paid on account Consolidated Allowance for expenses of the Chairman attending meetings in 1890	250 00
To paid on account Consolidated Accounts for expenses of the Secretary attending meetings in 1890	125 00
To paid on account S. W. Fowlkes for D. Draft per £50 paid him as a contribution towards his expenses in pushing Ceylon Tea in Australia	683 17
To paid on account His Imperial Highness the Czarewitch for presentation portfolio of photographs	126 50
To paid on account His Imperial Highness the Czarewitch, His Majesty the Emperor William and Her Majesty the Dowager Empress Frederick of Germany paid for presents of Ceylon Tea	784 62
To paid on account Lagalla estate for refund claimed as over remitted	150 76
To paid on account Prosecutions under the Merchandise Marks Act paid Wm. Martin Leake to retire draft per £40 8s 5d	532 47
To paid on account Postages and Petties	110 23
To Balance in N. O. B. C. Kandy at 30th June 1891	2,174 94

Amount paid at 30th June 1891	2,485 66
	R6,887 14

FOUNDATIONS UNDER WATER.—It is stated that a German military engineer has devised a new method for fixing a foundation under water. By means of a powerful jet of compressed air he drives dry cement down into the sand or mud at the bottom of a stream. The action of the water immediately fixes the cement, and it becomes like solid rock.—*Public Opinion.*
THE AGRICULTURAL COLLEGE recently established in Cairo is prospering very well. The Principal is Mr. Samuel Wallace, brother of Professor Wallace, of Edinburgh University, and he is heartily supported by the Egyptian Government. About 60 students have been admitted, many others having been excluded owing to lack of accommodation. A garden and farm of 300 acres is attached to the establishment, where experiments are carried out and the employment of Western tools and methods is demonstrated.—*Globe.*

MORE UPON THE SUBJECT OF MANA GRASS.

We are glad at length to learn that a very large measure of success has attended the experiments which have for so long been making at home with the mana grass which grows in such wild profusion on the mountain "patanas" of this island. Our anticipations previously expressed in these columns seem to have been for a very long time under a cloud consequent upon repeated failures of one kind and another, and the news that these have now been replaced by an, at all events partial, success, will be welcome no doubt to all who have the interests of the colony at heart.

Nevertheless we do not disguise from ourselves that much yet remains to be accomplished, and probably many as yet unforeseen difficulties remain to be overcome, before we can indulge in the expectation of seeing our formerly expressed anticipations realised. But at least we now know that mana grass pulp, when treated with 25 per cent of waste paper or of old gunny bags or other comparatively valueless material of that character, can be made into a stout and solid board, which has one advantage over that made from wheat straw, inasmuch as it is without that amount of silica which tends to make straw board a brittle and intractable material. We should have been glad to hear that our London correspondent had seen tea boxes formed in the solid from mana grass pulp; but although he has been promised that this can and shall be done, the required machinery had not when his last letter was written been completed. But he had seen two cylindrical casks or packing cases of considerable size made of the mana grass board, and he reports that these were as strong and as solid as could be desired. Very little ingenuity, he feels assured, is required to compress the pulp into the form of a box complete in itself in every respect save as regards the lid.

We trust that this assurance may be confirmed. Cylindrical packages such as have already been made would occupy too much space on shipboard to be likely to receive adoption by our planters, although in other respects they would appear to be admirably suited for the package of tea. It cannot be expected that the manufacture of jointless tea boxes could be carried on at home with mana grass pulp. In the first place, the freight homewards of the raw material would be prohibitory, and in the second, that of the empty square boxes outwards would not be less so. If, therefore, success is in the future to attend the manufacture, it is certain that this must be done locally, and in such positions as may ensure the cost of transport of the made boxes to estates being kept as low as may be practicable. As at present foreshadowed, it would appear that the Universal Barrel Company of Boxmoor which has conducted the latest experiments has it in contemplation to obtain from the Stanley-Wrightson Syndicate its patent rights as regards Ceylon, and possibly as regards other countries in which mana grass may be found in any abundance. Those secured, a factory containing the required machinery would be erected out here and started with a properly qualified man in charge. We can do no more to aid in the accomplishment of this when the time comes for doing so—should this arrive—than to suggest the sites the most eligible for such a factory. Water power it must of course have; and it should be so situated that it can possess its own siding to the railway. It will further be a *sine qua non* that it be in tolerable proximity to lands growing mana grass in abundance. Should

any of our readers be able to suggest sites fulfilling these several conditions, we shall take care that their suggestions are made known in the proper quarter at home, to which they would doubtless prove very valuable.

It may be a question whether, after a time, it would not be necessary to cultivate fields of mana grass; and we should think this could be easily and cheaply done, on the vast expanses of patana which stretch in all directions from Nuwara Eliya and which exist in other parts of the mountain region, on the western and eastern sides alike.

TEA-DRINKING.—A WARNING TO MOTHERS.

By DR. ANDREW ROSS, MOLONG.

[An exaggerated and misleading article. Tea is, on the whole, the best and certainly the most easily procured of the non-alcoholic stimulants. But, of course, there can be excess even in tea drinking, and there may occur occasional cases where constitutional peculiarities contra-indicate its use.—Ed. T. A.]

The following remarkable case is published with a view of putting parents and heads of families on their guard as to the evil effects arising from the use of strong tea drinking—in other words, the too common and pernicious custom of allowing young children to drink tea at meal time. Some few months back I was consulted about the health of a young boy between 5 and 6 years of age belonging to Mr. K—, and who was in the habit at meal time of partaking freely of strong tea. The boy until within the last 12 months had always enjoyed good health, but lately had become somewhat dull and stupid, with palpitation at the least excitement or exertion, a tendency to convulsions—very restless at night, and sleep much disturbed, loss of memory, with at times a giddy feeling, and both eyes much turned inwards and made to squint with a peculiar tremour of the eyes, as if suffering from some internal affection of the brain. The boy for his age was well developed, and born of strong, healthy parents, but he had of late showed every symptom of falling into a bad state of health with great restlessness, marked squinting of both eyes, and which twitched most severely. I at once diagnosed the case as one arising from the poisonous or injurious effect of the excessive use of strong tea drinking—a too common habit, I regret to say, amongst families residing in the interior. I told the parents, what I thought of the case, and the cause from which the illness I believed proceeded. I told the parents, too, that I could do nothing in the matter unless the injurious and pernicious habit of strong tea drinking was at once discontinued and abandoned, otherwise the boy sooner or later must succumb to serious illness, nervous prostration, or softening of the brain—in other words, anæmia or blood-poisoning,* the result of strong tea drinking. The parents at once acquiesced in my remarks, and made a pledge that my instructions should be strictly carried out, and that the tea-drinking regime for the future should be entirely discontinued, and nothing but plain water, water and sugar, or milk and water allowed at meal time. The result was that two months after I had been consulted the boy had completely regained his former health—the bad memory, convulsions, giddiness, and palpitation had disappeared, rest at night undisturbed and refreshing, and the boy being able to return to school. The symptoms of poisoning arising from the injurious habit of strong tea drinking in one so young was most characteristic, and I have no hesitation in saying (after long experience of bush babies and life) that a more cruel, pitiful, sinful, and pernicious habit of parents allowing young children of tender years to partake of so much strong tea at meal time has only once for all to be mentioned and condemned, and for ever abandoned by all sensible, well-wishing parents who have any parental regard and value the lives and health of their families. The case is by no means an isolated or ex-

* A "confusion of optaphs," with a vengeance!—Ed. T. A.

aggregated one, for I believe there are hundreds of such cases transpiring in our midst every day; but the ill health and treatment may be attributable probably to quite a very different set of causes than the one herein illustrated. I have no hesitation in saying that the ever-watchful physician fails in the performance of his sacred duty to the public if he does not warn parents against the too common evil and injurious habit of tea-drinking, a habit, I regret to say, far too prevalent and painful nowadays among young children of tender years, more especially in country districts, where such a treacherous beverage is partaken of by young and old at every meal. Prevention of disease is as much an essential factor in medicine and in the hands of the physician to point out such serious evils as that of the treatment of disease when it does occur, and therefore I sincerely exhort the head of every family (especially mothers) to beware in time of the insidious and suicidal evils arising from this too common, prolific, and fertile source of ill-health, disease and heart affections among children in families. For years I have, as a resident in the bush, watched the evil effects arising from the use of strong tea drinking, especially amongst the young, and I can truthfully say that parents who are fool-hardy enough to follow this baneful and pernicious habit of tea-drinking have only themselves to blame for having sickness in their families—aye, or even diphtheria, which in my belief, arises from this evil.* Over and over again I have endeavoured to warn parents against this evil custom, and have been pool-pooled, and laughed at perhaps by senseless people, for my pains; but I have the consolation of knowing that I do so chiefly in the interest and for the protection of poor unfortunate innocent little children and sufferers who unfortunately know no better. The arterial blood in youth is simply, in my candid belief, destroyed and rendered dark and anæmic by the too common error and prejudicial habit of tea-drinking which contains so much tannin in the infusion. [When infused too long.—Ed. T. A.]

Cocoa ought to be a much better and safer beverage for the young. Food and drink must exercise a therapeutic effect on the functions of the body, the constitution, and animal physiology for good or evil (however obscure their operation at times may be) as much as some of our potent medicine agents. The idiosyncrasy of the age is becoming so fastidious that some people are never satisfied unless the stomach is turned into a complete medicine chest, so careless are they to think or know the effects of medicine, food, and drink upon the system—in fact, swallow anything that bears the name of being a panacea for health, even the deadliest of poisons. In fact, medicine nowadays is nothing unless the most virulent and deadly agents are selected and prescribed wholesale. The days of preventive medicine are nowhere to be found in the category of the 19th century practitioner.—*Sydney Mail*, July 25.

BAMBOOS.—It is pleasing to note that this beautiful genus of plant is gradually gaining popularity. Indeed, it is a wonder how it is they have kept in the background so long as they are much superior to a good many of the Palms in cultivation; for the conservatory and general decorative purposes, it is hard to find their equal, as their lax and graceful foliage renders them suitable for mixing with all kinds of plants. Most of the species are either hardy or half-hardy, and very easy of cultivation, their chief requirements being a rather rich soil and abundance of water in summer. The following are a few of those best suited for general purposes. *Bambusa Fortunei* var. *variegata*, a very pretty dwarf-growing variety well adapted for pot work; *B. striata*, *B. antea*, *B. violascens*, and *B. nana*, the latter is rather a tender species, and does best when in a stove. The genus *Phyllostachys*, found in China and Japan, also contains many beautiful species, well deserving more attention from horticulturists; should the demand for them increase, many forms will doubtless be produced superior even to those existing at present.—*Gardeners' Chronicle*.

* Tea the cause of diphtheria!—Ed. T. A.
† Which is utterly untrue.—Ed. T. A.

CEYLON TEA IN AUSTRALIA.

The review of the Australasian tea trade for the year ended 30th June 1891, published by the Melbourne *Argus* and reprinted on another page, shows that India and Ceylon teas are rapidly superseding the China product in these important markets. The quantity of tea received from Foochow during the twelve months fell from 24 and 21 million lb. in 1888-9 and 1889-90 to 15½ million lb.; while the quality showed a great falling-off,—so much so that the customs authorities in Melbourne refused to pass large quantities as unfit for consumption. On the other hand the shipments of Ceylon tea increased from 916,000 lb. in 1888-9 and 1½ million lb. in 1889-90 to 2,900,000 lb. in 1890-91, the soft and flavoured Ceylon teas being much in favour with the public. We hope that they will become increasingly so.

WEIGHING OF TEA.

The following letter has reached us by the mail:—
I think the grievances which your correspondents have so very barely connected with tea-weighing in London are somewhat exaggerated. I do not mean that the individual cases are not figuratively correct, but my experience and that of others in London is that after allowance for draft, the teas from many gardens invariably come out almost exactly to garden weights; other estates constantly show a heavy loss, which leads us to conclude either that those gardens which are habitually accurate weigh with greater liberality, or that by superiority of package, accuracy of weighing machines and careful supervision they prevent loss.

It not infrequently happens that teas are sold in excess of garden weights, as you will see by enclosed account sales (which we sent back to Ceylon by last mail) after deducting the trade allowance.

When your correspondents write about a loss of 2 per cent or 3 per cent they include the draft or natural trade allowance, which they can minimise if they like, but which they will generally find it is their interest to increase.

The trade allowance is as all are aware one pound per package upon all packages grossing 28 lb. thus on a chest containing 150 lb. the grower allows the buyer ¾ per cent, but upon boxes of twenty pounds which may carry draft he allows the buyer five per cent. As but a small proportion of Indian teas comes in half-chests the Ceylon half chest seems to supply a special want both of the country and of the continent and we frequently advise our Ceylon friends to give their extra trade allowance and thereby probably secure a higher price for their teas.

I have referred to draft as a natural trade allowance because a very large proportion of the tea sold in the United Kingdom is retained in the very small quantities, from an ounce upwards and it is not possible honestly to make a chest of tea holding only 100 lb. weigh 400 quarter pounds. I think it has already been made clear to your readers that the trade allowance goes straight to the buyer and that the broker and merchant do not fatten upon it. The Board of Trade rules allow two pounds to be drawn from each hed, that is from each grade of a break, free of charge for sampling purposes, provided this sample is drawn after the tea is weighed up so even this small quantity comes out of the buyer's and not the grower's pocket.

Any further samples which are required, and they very often are required by merchant or broker, have to be returned in kind. But it does not yet seem to be quite clear to all that the Board of Customs collects duty upon the trade allowance.

For instance when an invoice is sent to a country dealer it is sent thus:—
To 20 ½ chests Ceylon Pekoe 1,000 lb. at 9d £37 10s
To duty and customs charges &c. 1,020 lb. at 4d £17 0s10d
There is not and I don't believe there ever will be any

getting rid of this trade allowance. It seems unreasonable that the buyer of a 25 lb. box of tea should have the same allowance made to him as the buyer of a hundred and fifty pound chest has, but if it were not so you get into fractions and the trade naturally abhors the introduction of fractions into book-keeping; besides things are cut so fine that the buyer seriously considers the draft when purchasing tea.

Dismissing the question of trade allowance which must not be looked upon as loss, my experience of actual loss comes very near that of Mr. John Hamilton. The following is the result of the last twenty sales for which we have rendered accounts to Ceylon:—

	lb.
Amount of tea invoiced	.. 104,224
Sold 101,975
Draft on 1,478 packages	.. 1,478
Loss 771
	104,224

There was a time when the Colombo Wharf, the holds of ships and the wagons or barges which convoyed tea from ships to warehouses would have accounted for a good deal of this loss, but packages have much improved and I do not think there is much loss in transit now, and the want of an even tare is the root of the evil.

Japanese chests as a rule tare more evenly than Ceylon-made chests, and there is consequently greater loss in the use of the latter.

One of your correspondents wants to know what we have to do with tare and why dealers cannot contentedly buy his chests said to contain 50 lb. of tea.

This simple system would work well by conveying a tin of biscuits from Aham Saibo's shop to your correspondent's bungalow, but in sending goods from a warehouse perhaps over several different railways to their destination, tare cannot be dispensed with. Even with the obsec of gross, tare and nett weighing we sometimes find that a hardy grocer in the north defies Her Majesty's Customs certified weights and declines to pay for more tea than his own weighing machine shows him to have received.

Fine teas of course show greater waste in bulking than coarser teas, not because they are high-priced, but because of the finer grain, and your correspondent will I think find there is greater loss or dust than on any other tea.

What it is most desirable we should get at is how the tare is affected by the voyage home.

Our London Association asked the Planters' Association to help us in a test case, but so far nothing has been done. If any planter will take this up and pack a break, say partly in Japanese and partly in Ceylon chests, weighing in beam scales, which is the most reliable weighing machine of all, and arrange that his agents should personally see the weighing done on this side, he would confer a benefit upon all interested in the growth of Ceylon teas.

My experience is that the preventable loss is far less than your correspondents calculate, but is still a very serious loss of about three-quarters per cent which an even tare and a careful system of weighing can do much to minimize.—Faithfully yours, J. L. SHAND.

OUR LOCAL TEA COMMITTEE AND THE CEYLON ASSOCIATION IN LONDON.

It is much to be regretted that there should have arisen any risk of friction between these two bodies. Let us, before discussing the position, submit to the minds of our readers the broad facts as originally existing. A Mr. Lough (see notice of his enterprise elsewhere in today's issue) has been foremost in the endeavor to introduce the practice of drinking tea among the Parisians. Desiring to extend the business he has created in the French capital, he asked for recognition—not be it observed for pecuniary help—by the Ceylon Association in London. The Tea Com-

mittee of the latter body met to discuss Mr. Lough's proposals, and with a single exception—that of Mr. Hutchison of the Ceylon Tea Growers Company—(Mr. Lough seems to be connected with the "Tower Tea Company,") accepted them in a limited degree. Mr. Hutchison stated Mr. Lough to be the vendor of packet blended tea labelled in a most deceptive way, one most injurious to the reputation of Ceylon tea, and he embodied his objection to the support promised to Mr. Lough in a letter, not intended to be made public, to an agent of his own company in Ceylon. This letter was submitted to the Tea Committee of the Planters' Association, and the *ex-parte* statements made by Mr. Hutchison were acted upon in a manner likely to give considerable annoyance to the Tea Committee of the Ceylon Association. The resolution passed was highly condemnatory of the course followed by the sister Committee sitting in London. The members of this body were summoned to consider the communication received, and the purport of the letter addressed by their Secretary to the Planters' Association was given in our London Letter by last mail. We cannot but think that the London Committee did wisely in refusing to either consider or pass any formal resolution on the subject. No doubt they felt much annoyed at the rebuke passed upon their action, and this feeling would probably have found strong expression had any formal resolution been agreed upon. As it is, although we can hardly consider that the home Committee can be altogether acquitted of some rashness in dealing with Mr. Lough's application for recognition, the letter addressed by their Secretary in reply to the imputation, made clear, at all events, that there exist two sides to the question, and that they felt bound to sink some very natural feeling of annoyance at acts committed by Mr. Lough, in order that they might avail themselves of his services, these being, according to all accounts, of an exceptionally valuable character. The letter referred to urges on behalf of Mr. Lough that he could plead personal ignorance of the act of false labelling which had been going on under his name; that when it was brought to his notice at the meeting referred to, he took immediate steps to put a stop to the course complained of and withdrew the objectionable advertisement relating to it which had up to that time appeared in the *Grocer*. He therefore made the *amende honorable* in the fullest degree, in accordance with a promise made by him. Thus purged of further offense, the actual work done by Mr. Lough might be weighed in the balance, and it received full acknowledgement of its value by the Home Committee. Mr. Lough has undertaken at very great personal cost and trouble the labour of creating a taste for tea drinking among the French, and his efforts have had some considerable amount of useful result, in which he asked that Ceylon tea might share. It would, perhaps, have been hypercritical to have refused to grant to him the small support he asked should be given him by the Ceylon Association in London. It cannot be denied, we think, that our own local Committee wrote in too strong terms solely upon the authority of Mr. Hutchison's private letter, which had not been written to be seen by the Committee. We cannot be surprised that the rejoinder from London, in addition to its other arguments, expresses regret that such condemnation as was passed should have been determined upon without prior reference of Mr. Hutchison's letter to the London Committee. We trust that the incident may pass over without further friction between the two committees, for that which has arisen is much to be regretted and its repetition deprecated.

Correspondence.

To the Editor.

JAVA REVISITED.

Sana Estate, Ratnapura, Ceylon, July 27th.

DEAR "OBSERVER,"—"The Ceylon Planter on the Prowl" has (I verily believe) good reason to thank Heaven that he is not as other men are, when he sees the want of "go" in other nations.

On revisiting, I find planting Java stands just about where it did, when I was there in the year of our Lord 1883. "General Funk" seems to prevent them going in for any bold stroke of planting enterprise. While, in the 8 years gone by, the whole face of Ceylon has been changed for the better:—our brothers in Java as a class are still crying over the low rate for the cinchona nit, and are inclined to growl at the Brunswick quinine manufacturer and at the former rival, the Ceylon planter.

Buitenzorg Botanical Gardens are as pretty and instructive as ever; and Dr. Treub is making experiments with my indigenous tea seed I took down with me. It only took 10 days from Ratnapura to Buitenzorg, and when the cases were opened they were found quite fresh, contrasting favorably, it was said, with what had been imported from Assam a month or 6 weeks or so en route. Further, Dr. Treub has kindly promised to keep careful 'count and reckoning' of germination &c. and to send me full details, 3 or 4 months hence, when the experiments are completed, and these I will send you on receipt for publication in your *Tropical Agriculturist*; a periodical I found as much appreciated in Java as in Ceylon:—even perhaps more thumbed and carefully studied there, than here.

My boss-kangani *Tirrimally* whom I took with me will have great yarns to spin in the lines when he gets back to the estate, about the volcanic wonders of *Papadaya* which we also visited. Judging from the copious samples of sulphur he secured, his thoughts were in Ceylon, like the Dying Gladiator. God bless the Duke!

It must not be imagined that the Dutch planters are not aware of the superior merits of a high class indigenous seed as compared with the original China jat which they planted first; recent high prices, from a few Java estates growing 'indigenous,' have accentuated the belief. In fact, I saw some leaves from Mr. Van Hengst's estate that equalled anything we can show in Ceylon, but their trees are mostly young, and not seed-bearing as yet, for a large demand.

What impresses one is the seeming *slowness* with which they act, and the want of boldness in going in for a "brand new stock, lock and barrel" policy, when the old musket is found, and *proven*, unfit. Since the events of A. D. 1870 even a Frenchman recognizes some merits in Herr Krupp's manufacture.

Individually, they are as hospitable and good-natured as ever. I was at *Soekaboemi* the day of their Planters' Association meet, and was invited to be present, but I did not think fit to go: it would not have been etiquette to have talked 'quina and its compounds';—a red rag to a bull, or a spark (however insignificant in itself) in a powder magazine.

To sum up the whole matter:—They need more new blood. If *Sumatra* (north of the equator) were annexed by the Straits Government, the *Atcheen* row would soon be settled; while if *Java* (say 103°

E. Long. Greenwich) were partitioned (as a heritage for Young Australia), there would still be enough playground left our Dutch cousins between *Batavia* and *Walkoop Bay*, for them to romp around in.—
Yours truly,
WM. G. SANDISON.

KAPU, KAPOK, AND PULUN.

Colombo, July 28th.

DEAR SIR,—Could you or any of your numerous readers inform me and the general public through the medium of your journal, the correct meanings of "kapu," "kapok," and "pulun."

So far as I am aware the term "kapu" is applied by the Sinhalese to weaving cotton, and "pulun" is usually applied to what is known as tree cotton or silk cotton. But the proper meaning of "pulun" is any soft fibrous substance. Hence the Sinhalese speak of "kapu pulun," weaving cotton; "imhul pulun," the tree or silk cotton, and "wara pulun," the cottony substance found inside the pods of the *Calatropis gigantea*. The word "kapok" is a commercial term of recent introduction to designate the tree or silk cotton, the "imhul pulun" of the Sinhalese. There is a certain amount of confusion in the use of these terms especially among colonists; and it will be useful to know their proper meanings.—Yours truly,

KATU IMBUL.

[In our issue of the 11th we had on these words, to which we would refer our correspondent.—
Ed. T. A.]

AN ENEMY OF TEA.

Uva, July 31st.

DEAR SIR,—By today's post I am sending you some sort of caterpillar that I found devouring my tea; every leaf on one bush was perforated and they had begun on several others. Are we to consider them an enemy of our tea?—Yours truly,
INQUIRER.

[Our entomological authority writes:—"Caterpillars of a moth of the genus *Psyche*, living in a case constructed from fragments of leaves, and lined with silky threads. They can certainly be considered an enemy to the tea tree, while they themselves are well protected from enemies. They are very common and widely distributed."—
Ed. T. A.]

THE COFFEE SEED FROM BURMA.

Diggings, Aug. 1st.

DEAR SIR,—The coffee seed sent me by my son from Rangoon came up in the nursery all well but I am sorry to say now, the small plants have not "enjoyed immunity from leaf disease," and I intend writing to tell him so.—Yours very truly,
JOHN STEPHENS.

ENGRAVING ON METAL.—A Russian electrician of the name of Kolomtrew is reported in the St. Petersburg papers to have devised a process of photographing and engraving on metals by means of electricity, rendering the etching method unnecessary. He is about to start for abroad to dispose of his invention.—*Electrical Review*.

PLANTING AND LABOUR IN SOUTHERN INDIA form the subject of an article in the *Madras Times* given elsewhere. It will be seen that the planters across the water are as badly off for labour as their Ceylon brethren, whom the *Madras Times* recommends to copy in forming a united Association like the Planters' Association of Ceylon.

BARK AND DRUG REPORT.

(From the *Chemist and Druggist*.)

LONDON, Aug. 1st.

CINCHONA.—The periodical auctions held on Tuesday were of very moderate extent. They consisted of:—

	Pkgs.	Pkgs.		
Ceylon cinchona	926	899	of which	were sold
East India cinchona	353	327	do	do
Java cinchona	67	60	do	do
South American cinchona	840	82	do	do
W. C. African cinchona	60	60	do	do
Total	1,783	1,429	do	do

Of the Eastern barks very little was bought in, and throughout the sales competition was well maintained, becoming more lively towards the end. The quality of the bark offered was poor. The market may be described as firm, but without notable advance in value. The unit remains at 1½ per lb.

The following are the approximate quantities purchased by the principal buyers:—

	Lbs.
Agents for the Brunswick factory	59,392
Agents for the American and Italian work	59,649
Agents for the Mannheim and Amsterdam works	51,769
Agents for the Frankfurt O/M. and Stuttgart works	49,521
Messrs. Howards & Sons	44,884
Agents for the Anorba factory	39,451
Mr. Thomas Whiffen	5,350
Sundry druggists	12,977

Total quantity sold	345,186
Bought in or withdrawn	40,005

Total quantity offered ... 385,191

It should be well understood that the mere weight of bark purchased affords no guide whatever to the quinine yield represented by it, firms who buy a small quantity of bark by weight frequently take the richest lots and *vice versa*.

NUX VOMICA.—The market remains firm. Arrivals from Coconada and Colombia this week amount to 298 cases.

QUININE.—The market was dull during the early part of the week, and 5,000 oz. Anebich quinine changed hands at 10½ per oz. Since Wednesday the market shows some inclination towards a recovery, and some 5,000 oz. German bark (B & S or Brunswick) from second-hand holders have been sold at 10½ per oz. Howard's brand was rejected in price—11 per oz.—by the manufacturers on Wednesday, while being now noted at 1s 3½ to 1s 4 per oz., according to quantity.

THE TEA EXPORT FROM JAPAN IN 1890 is thus referred to in the report of the British consul at Yokohama:—

Tea.—The increase in the quantity of tea exported amounted to 3,568,061 lb. over that of 1889, and was about equal to that of 1888. In consequence of the mildness of the winter the tea season began earlier than usual, the market opening about the middle of April. The quality of the leaf was below the average, owing mainly to excessive moisture in the spring. The demand on the American Continent has run, as heretofore, chiefly in the direction of low-priced grades. The result, as regards choice leaf, here is that but little of it is prepared for export; the prices offered do not pay the cost of production. The excessive fluctuations in exchange had their effect in this as in other departments of commerce; but the year may be considered on the whole to have been a fairly good one for exporters, who had, for one thing in their favour, the low rates of freight ruling. It should be noted that efforts are being made to introduce Japan Congou into Russia, but it is questionable if the quality of the article will be sufficiently good to ensure success in this. *Destinations of the tea.*—The following analysis of the destination of the tea export may be of interest:—To Chicago, 8,150,554 lb; Canada, 8043,707 lb.; New York, 6,368,468 lb.; California, 3858,861 lb.; Europe, 203,061 lb.; and the balance, for the most part probably to China. The routes by which the tea has been carried are:—By Pacific Mail and Occidental and Oriental steamers, 10,933,042 lb.; Suez steamers to New York, 2,807,471 lb.; Canada, 3,254,268 lb.; Europe, 333,061 lb.; Sail and rail via Tacoma, 5,112,762 lb.; to San Francisco, 35,532 lb.; via the Cape to Canada, 59,102 lb. There has been an increase in the shipments by rail to Tacoma and the North Pacific Railway, and by the Canadian Pacific line. Suez Canal steamers the shipments have been about the same as in 1889.

THE CALCUTTA BOTANIC GARDENS.—We have received Dr. King's annual report for the year 1890-91, and quote the resolution of the Government of Bengal, as follows:—

The Report for the year shows that steady progress has been made in improving the Botanic Garden, not only as a scientific centre of the highest value to all botanical students, but also a pleasurable and instructive resort to the public. More than 20,000 specimens were added to the Herbarium, illustrating the Flora of regions so widely removed as Central Asia, Australia, Assam, Perak, the Shan States, the Khasi Hills, the Andaman Islands, and the Great Coco Island. To the contributors of these specimens, Messrs. Mann, Luce, Gamble, Curtis, Ridley, S. Peal, and L. Wray, Generals Collett and Gataore and Baron von Muller, the thanks of Government are due. Arrangements were also made for continuing the work of collection in Assam, Upper Burma, and the Andamans. A third volume was added to the interesting series of garden annals, containing a monograph by Dr. King and Dr. Prain on certain Indian and Indo-Malayan species. Unfortunately, however, owing to unavoidable delays, it was found impossible to publish the volume within the year. Both the Superintendent and the Curator of the Herbarium also contributed valuable papers on botanical subjects to the Journal of the Asiatic Society. The Lloyd Botanic Garden in Darjeeling, which is under Dr. King's supervision, is reported to be in good order. Under recent arrangements the Curator of this garden is charged with the task of improving the station of Darjeeling by planting and looking after young trees. In course of time it is hoped that the damage done in past years by the wanton destruction of fine trees may be in some measure repaired. The thanks of the Lieutenant-Governor are due to Dr. King, the Superintendent, and Dr. Prain, the Curator of the Herbarium, for the successful administration of the garden during the year.

THE CHEMISTRY OF THE OCEAN.—The study of the 685 densities of the water of the sea made during the expedition of the "Challenger," and the report of 103 series, of which each extended from the bottom of the ocean to the surface, the discussion of the results of the deep soundings obtained by the "Pola" in 1890, the various theories relative to the chalk formations by chemical action with the necessary intervention of living creatures, and, finally, the different observations of oceanic analysis with which M. J. Thoulet has been occupied for several years past, relative to the existence at the bottom of the ocean of two belts of water, one in repose, and the other in motion are all in accordance with the following hypothesis:—The surface of the ocean, submitted to climatic changes, is in a state of heating and evaporation more or less intense. The variations which result in the real density and in the climatic composition of the waters, due to the mechanical action exercised by the wind, give in the place of horizontal marine currents those more or less vortical, which cross between these where they overlap each other, with extreme quickness and in different directions. These together constitute oceanic circulation, which is effected almost entirely in a very shallow belt, about 500 fathoms in depth. The substances, only slightly soluble, contained in the waters of the seas, and brought to the ocean by the fresh waters which are far more dissolvent, attain, at a certain depth, their limit of solubility and form precipitates. Becoming solid, they descend vertically, penetrate into the still belt, and at last reach the soil at the bottom. Surrounded by immovable water, they dissolve and increase the proportion of salt contained in the deepest stratum of the water, and that immediately in contact with the soil. They then spread, and with the extreme slowness, increase the saline quality of the adjacent waters, and at the same time extend to the stratum next to the soil which is not saturated, and consequently continues to dissolve the new material which arrives without cessation. The submarine soil is then a kind of centre of chemical activity, fed by fresh material from the surface, and radiating slowly towards the surface.—*Revue Scientifique*.

THE SOUTH INDIAN PLANTING INDUSTRY AND THE LABOUR SUPPLY.

It appears to us that a serious crisis in the Planting Industry of Southern India can only be avoided by prompt action on the part of the different Associations. It is well within the cognisance of our Planting readers that during the year 1890 all estates, in addition to the terrible injury and loss of crop occasioned by leaf disease and an abnormal atmospheric disturbance, suffered very considerably from want of a sufficient labour supply. The reason of this we have not far to seek. All the estates in the Wynaad, Coorg and Mysore Districts have for years past looked to the Mysore country as the chief source from which they could draw the necessary labour to cultivate their estates and harvest their crops. Competition has been very keen and the Cararese cooly has been pampered to his heart's content. On each estate heavy advances have been given to the same maistries and for the same coolies year by year, advances never really recovered, but only tacked at the end of each working season, to be again immediately advanced, with an addition, more or less, on a fresh contract. Also it is not at all unusual for a dishonest maistry to take advances during a single season from two or more estates, and divide his labour-supplying powers in proportion. Under such a system both maistries and coolies have grown rich and independent, land has been taken up in Mysore, fields cultivated and houses built with the Planter's money; year by year the advent of the coolies to the estates has been postponed and, whilst formerly coolies used to return regularly to the estates by the end of May or early in June, last season it was well on in September before they made their appearance. We are aware that during the present season labour is more abundant, but what happened last year may recur during any year, and the estates will suffer. We would impress on our Planting friends that if they wish to secure a steady and sufficient supply of labour, other districts must be tapped; there are thousands of coolies in the southern districts, and a proper organisation is all that is needed to reap the benefits of their services. Mysore is played out, and can never again supply all the labour required for the existing coffee cinchona, and what we hope is the growing tea industry.

We are quite aware that we shall be met here with arguments that it is not the slightest use endeavouring to draw labour from the Tamil country under the existing condition of the labour laws of the country, and with especial reference to the working of Act XIII. of 1859, and we quite agree, but what we would urge is agitation. The Government ought to be fully aware of the immense importance to the country of the Planting industry, and we cannot but think that if reasonable representations are made to them by an united body, such representations will receive full consideration. By an united body we do not mean the communications of any one Association. We recognise the work that has been hitherto done by the various Associations, and more especially by the Wynaad Planters' Association, which has never ceased to be active since its original formation in 1856, but we say the time has come for the unification of all the various Associations in Wynaad, Travancore, Coorg and Mysore, with one common object—the welfare of the whole Planting community. There need be no jealousy; apart from small local interests, there will always be the one great question in common, an efficient labour supply, and other questions, such as cattle trespass, &c., are of equal interest to all. Recently there has been an approach to a unification of interests amongst the different Associations as witness the united petitions as regards the Cattle Trespass Act, and the more recent one, now in course of consideration, concerning the working or rather the inoperativeness of the Contract Act XIII. of 1859, but our planting friends will pardon us if we argue that this is not enough. They must march with the times and follow the example of the Commercial and Trades Unions at Home, and so work together as to exert the utmost possible pressure on the Government of the day.

It cannot be denied that representations from a Central Association, composed of delegates from the different bodies and empowered to present a united front on all questions of general interests, would have far more power than the casual and intermittent complaints from Wynaad Travancore, Coorg and Mysore. The case of Ceylon is analogous. In that colony there was originally only one Association, the Ceylon Planters' Association; as the estates increased, and new districts were opened up, other and local Associations were formed, but in a few years it was found necessary to combine, and all the various bodies found it to their interest to affiliate with the Parent Association and present a united front on all questions of general interest. They did more than this; they never rested until their states was so far recognised as to lead to the appointment of a Planting Member of Council. It is almost unnecessary to point out the advantages that the Ceylon planters have gained by united action, and there is no reason why the planters of Southern India should not obtain similar benefits, or such as are suited to the different requirements of these districts, if they will unite into one central body which shall be the mouth-piece of the whole community. There can be no doubt but that the excellently organised institutions of Ceylon helped very considerably in enabling the planters in that colony to recover from the prostration caused by the comparative failure of the coffee plantations, and to build up so quickly the successful tea industry to an extent that is the admiration of neighbouring countries.

With a well-conceived and established Central Association, formed by the planters of Southern India, schooled by picked and experienced men from the different districts, and kept posted up by the branch Associations with every necessary detail of information, the gain to every planter would, in our opinion, be directly or indirectly enormous; for whilst there are thousands of acres, that are available for planting, remaining undeveloped, owing to the dread uncertainty of a sufficient labour supply; whilst the courts of law in almost every district require considerable expansion and improvement; whilst the construction of necessary roads and bridges is delayed; and whilst railways are as yet in the womb of the future no fresh capital will be attracted to the country and its development is retarded. As regards rail communication we understand that a survey of an extension of the Southern Mahratta line from Nanjanogode in Mysore to Gudaloro in S. E. Wynaad has been sanctioned, if it has not already been commenced, and a further extension thence through the Wynaad to the Western Coast can be only a question of time. Other extensions from the existing lines to Coorg and the Mysore coffee districts are also talked about. Those and other projects would be hastened if the countries were more settled and developed, and, to make such settlements possible, planters must combine to urge on Government the improvement and the perfecting of the labour laws. Immigration from the congested, and, at times, famine-stricken districts of Southern India, would benefit the coolies, the planters and Government, and whilst the latter give every encouragement in their power to the immigration of these coolies to Ceylon, Mauritius and other places, they ought surely to be equally ready to enact such laws as would enable the planters of Southern India to keep such of the labour as they require, at home, and thus develop the country they possess and increase its prosperity and revenues. We hope to return to this subject on another occasion, and shall be glad if its ventilation in our columns should lead eventually to the furtherance of the important interests of the Planting community.—*Madras Times.*

NOTES ON PRODUCE AND FINANCE.

COFFEE COMPANIES AND TEA CULTIVATION.—From the reports issued by two coffee companies, the Onvah and the Spring Valley, it will be seen that the cultivation of tea is a prominent feature in the operation of these concerns, whose titles might be altered with advantage now that they are tea as well as coffee companies.

LAST WEEK'S TEA SALES.—The demand for Indian tea, says the *Produce Markets' Review*, continues to improve, and a good business has been transacted. Although the recent imports are not of better quality, with few exceptions, than the previous shipments, the decline in values has imported more confidence to buyers, who now appear disposed to replenish their greatly reduced stock at the comparatively low prices ruling. Most of the supply brought forward consisted of tea under 10s per lb, which has been readily taken, but as the quantity offered has been sufficiently large to meet the enquiry, prices have remained steady throughout. A few breaks of fine tea from the Assam district, although not of exceptional quality, were keenly bid for and fetched high prices, which indicates that good tea is wanted, and will meet with a brisk demand where attainable.

AMERICA AND THE CHINA TRADE.—A New York paper, under the head "Mutations of the China Trade," notices the failure and retirement from business of the American firm of Russell and Co., of Hong Kong. This event marks, it is said, a distinct change in the trade between the United States and China. The trade has not been extinguished. It has merely changed hands, and has gone from Americans to Englishmen and Chinese. The once splendid sailing vessels which traded between New York and China have disappeared, and many old firms which used to trade directly with China have gone out with them. The business is still going on, however, although indirectly. The failure of Messrs. Russell and Co. resulted simply from persistence in doing business upon old methods. The writer says nothing about the high Protectionist system of the United States, which has tended to destroy direct trade with all countries producing merchandise which is wanted in American markets, and to compel American buyers to receive it indirectly, at additional cost, through the intermediation of merchants in other countries.

THE PINE-APPLE INDUSTRY.—There are less profitable industries than the cultivation of pine-apples. The pine-apple crop in Bahamas last year realised £49,795, as compared with £25,558 in 1889. Of canned pine-apples there were exported 26,789 cases, valued at £6,126, and in 1889 the export was 21,633 cases, with a value of £4,500. The Governor of the Bahamas says steady progress continues to be made in fibre cultivation, with increasing faith in its value and permanence. The importance of pineapple leaf fibre is fast developing. Professor Edison has directed his attention to the matter of decortication and he hopes he has found an effective method which avoids waste. The treatment is by a solution of crude petroleum, and the Government of the Bahamas are now in communication with the professor. If the results meet our requirements, a most important end will be attained, which will have the further advantage of enabling small cultivators to dress their own leaves instead of being compelled to sell them at a loss to a large neighbouring planter, who is able to procure a machine. The process being enterprised by Professor Edison embraces other and most valuable interests in the colony. Many thousands of tons of pineapple leaves are now annually left to waste. The fibre commands a high price, from £60 to £80 a ton, for use in fine textiles. The small quantity now produced comes from China, where it is roughly and expensively prepared for want of a machine sufficiently delicate to extract the tender fibre without injury. The proposed mode would seem to meet this difficulty, and all strain or friction is avoided, and the result of pending enquiries is looked for with great interest. The immediate effect of successful experiment would be to turn a wasted product into an article of much value, adding substantially to the returns of pineapple cultivation, and this process may be applied to the growing crop. It is understood that the same solution may be used many times, and, if present hopes are realised, the petroleum will be admitted free of duty now imposed.—*H. and C. Mail*, July 31st.

TEA DEALERS IN COUNCIL.

At the annual meeting of the members of the London Wholesale Tea Dealers' Association, held last week,

under the presidency of Mr. Francis Poek, the subject of the recent Customs order about weighing tea to the half-pound was referred to in the report as follows:—"An order was issued by the Customs authorities giving notice that tea would be weighed to the half-pound instead of the pound, which had been the rule since tea was first imported to this country. This alteration was so manifestly unjust to buyers, and would have involved such an immense amount of clerical work, that your committee opposed the change by all the means in their power, by representations to the Customs authorities and the Chancellor of the Exchequer; and also by convening public meetings upon the subject. The Customs at length received instructions to rescind the order, and although these meetings involved much labour and expense the successful result fully justified the course adopted." Nothing, said the chairman, showed the absolute importance of the wholesale trade holding and working together for their common interests more than that particular fight which they had with the Chancellor of the Exchequer. The change would have involved an immense amount of trouble and annoyance to the wholesale trade, and would have resulted in very considerable loss to their customers if it had been carried out, and had it not been for the prompt action taken by the association there was no doubt it would have been carried. The report then went on:—"Complaints have been made of the improper condition in which packages of tea are left in some bonded warehouses after inspection, and representations have been made to the Committee of the Tea Clearing-House, which it is hoped will lead to the chests being more promptly fastened up in future. An improved method of ascertaining the average tare of teas by always selecting an odd number of packages has been adopted, which will lead to a more just tare being fixed, particularly in the case of China teas." He thought they would have to keep careful watch over that matter, as well as upon another matter very nearly akin to it. There was no doubt that a great many teas were imperfectly bulked, and some of the warehouse keepers under pressure to get the teas forward, if they had not got the whole parcel in their bonded warehouse, would bulk what they got and take the chance of the rest. It was a very serious matter which involved them as wholesale dealers in a very great deal of trouble with their customers, and it was often an actual injustice to them. The committee had considered that matter a good deal, but as yet had not come to any definite conclusion as to what action to take with respect to it; but it was a question which must be carefully watched, and they thought it would be a good plan if some houses connected with the association would send in to the secretary any complaint of the sort they might have, with the name of the bonded warehouses where it occurred. If that means the warehouse where the bulking was bad would soon be brought to book. The secretary would be able to register all complaints he received, and then they would be able to say to the sinning warehouse, "Look at your record! there are forty cases of bad bulking against you as against an average of three or four in other warehouses." In that way he thought they would be able to put a stop to the practice.—*H. and C. Mail*, July 31st.

THE CEYLON TEA FUND.

THE GIFTS TO THE EMPEROR AND DOWAGER EMPRESS OF GERMANY.

Secretary's Office, No. 12, King Street, Kandy.

August 22nd, 1891.

The Editor, *Ceylon Observer*,

SIR,—I am requested by the Standing Committee of the "Tea Fund" to transmit to you for publication letter from the Secretary of State for Foreign Affairs, Berlin on the subject of the presents of Ceylon Tea sent to His Majesty the Emperor, and Her Majesty the Dowager Empress Frederick, together with the authorized translation thereof.—I am, sir, yours faithfully,

A. PHILIP,

Secretary to the Planters' Association of Ceylon.

(Translation.)

Foreign Office, Berlin, 25th June 1891.

I have the honour to inform the Planters' Association that I have transmitted to His Majesty the Emperor and to Her Majesty the Empress Frederick the four chests of tea which have been sent here through the Imperial German Consul at Colombo.

His Majesty the Emperor and Her Majesty the Empress Frederick have been graciously pleased to accept these presents and to direct me to transmit to the Planters' Association their Majesties' sincere thanks for this courteous attention.

It gives me much pleasure to bring this to the notice of the Planters' Association.

(Signed) MARSHALL,

Secretary of State for Foreign Affairs.

The Planters' Association of Ceylon, Colombo.

BANANAS.

are thus noticed in a report on the Trinidad Experimental Farm:—

Collectively there are 21 acres under "Gros Michel" banana. This has proved a capital nursery, furnishing during the past two years upwards of 100,000 plants for distribution, and as many more are ready for the same purpose. The bananas were planted 8' x 10', but this is too close for good fruit-bearing—12 feet square apart should be the distance; all suckers should be kept out down to the bearing plant, and one only allowed to grow when the parent stem is showing signs of fruit. This will ensure a marketable ration lunch. Shipping bananas from here has not proved successful. Nearly 1,300 bunches were shipped to New York, and though a few bunches realized top prices, sufficient was not obtained for the whole to cover expenses; 12 bunches, packed in crates, were shipped to Covent Garden, London, also unsuccessfully, chiefly from want of knowledge in packing. From instructions since received in this matter, hopes are held out that bananas might reach London sound. Full particulars of this experiment were published in the *Record* for February, 1891. Attention has recently been turned to drying this fruit, at first in the open air; but owing to the damage by myriads of insects attracted by the sweet fruit, the dust, etc., a failure was anticipated. This has however been remedied by the Hot Air Fruit Drier, properly known as the "Etna Pneumatic Fruit Drier," and I am happy to report in favour of the good work done by the machine. This is proved by the dried fruit being accepted in London, New York and Canada at remunerative prices. Orders are on hand for these places for more than two tons. Samples have been sent to Germany, Russia and France and other countries. In advocating drying bananas I by no means suggest that the export of the raw article should be given up—only that the drying affords a means of disposal to those whose means of inland transport prevents their profitably offering the fruit for shipment. The fruit can be dried within 24 hours at a temperature from 130° to 160°; higher than this the fruit hardens. The drying is done here in the daytime and the fire put out at night; any kind of fuel answers for firing, from patent fuel to cocoa wood chips. The fruit should be as large as possible and quite ripe, the skin to be removed and the fruit then lightly scraped. Whilst in the drier the fruit to be turned twice or three times carefully to ensure an even drying. The fruit may be seen undergoing the process any day, and a visit will furnish all information desired. I certainly am of opinion that a dried fruit trade would prove a profitable one, and it should receive the attention it deserves. No great amount of capital is required or even skill, and some of our smart young planters ought to take it up. An article in the *Record* for April, 1891, fully demonstrates the above. *Red Bananas*.—A field of this variety, about 5 acres, has been planted with a view principally of obtaining fibre from the stems. The red banana yields the finest fibre of our bananas, and would prove of value in connection with the manufacture of other fibres. In 1886 a sample of the fibre

was submitted to His Excellency the Governor who obtained a report from Messrs. Ido & Christie on its value. The sample was considered to be worth £25 per ton. From the many advantages offered by this plant, doubtless, in the event of a fibre industry arising, it will receive the attention it deserves. A stem weighing 100 lb. will yield between one and two pounds of clean fibre. 700 plants to the acre would give an annual yield of more than half a ton of fibre = £12 10, less cost of production, freight, &c., and this ought to leave half profits to the producer. The fruit of the red bananas was used for cattle food. Cooked with a little salt they have proved to be an excellent feed, and being rich in starch and albumen they improve the food value of milk. The stock are exceedingly fond of it, and a herd fed with it, mixed with a proportion of cake, would afford manure of great value. Whilst on the subject of bananas I must mention the "Meke." Last mail a sample of 7 lb. of meal prepared from the Moko plantain was forwarded to London for which the correspondent offered sixpence per pound. Receipts were also supplied for preparation in cooking. Great attention has been drawn to banana meal by the observations made by Mr. H. M. Stanley in his book "Darkest Africa" and which as an advertisement should not be lost sight of. No banana gives such excellent meal as the "Moko," or so agreeable in flavour and taste. The preparation of the meal is as follows:—The green Moko was skinned, sliced thin and dried in the fruit drier; then ground fine in ordinary corn mill and afterwards sifted through a muslin sieve: this latter removes any fibre and leaves a delicate fine meal. The sieves dry in two hours. A 15 lb. bunch will yield 3 lb. of prepared meal which at sixpence per pound 1/6 per bunch. Two women could prepare 50 lb. of meal per day. The cost of production, packing, &c., has to be considered, but the price obtained must be considered a satisfactory one; at least it is better than now obtained, which may be said to be nil.

NOTES BY "WANDERER."

Aug. 24th.

Colombo has seen more of the GARDEN PLANTER for the last fortnight than his factory has, which may in some measure account for the better class teas the factories are now turning out! However the true reason of the improvement is that there is plenty of withering room, and no hurry in the rolling and drying. Is it the case that the fine districts of Bogawantalawa, the Agras and Kandapolla are beginning to lose the flavour character of their teas. Some planters are of opinion that the teas first taken off a new estate say for six months are distinguished for flavour, but that when the fields get older, the flavour goes off and strength of liquor takes its place. This is exactly what has taken place with tobacco wrapper leaf, Java at one time had a good time of it, Sumatra followed suit, and now the cigar manufacturer is at his wits' end for pasture new in the Straits and Berneo.

CACAO.—You don't seem to be sufficiently alarmed at the important information you chronicle in the *Observer* and now in the *Tropical Agriculturist* of August, page 93. You say that in ten months the exports of Java cacao have run to 10,000 cwt. This an increase of 8,600 cwt. over the previous years. Are you sure you are right, and if so what has become of this extra cacao? The cacao blossoms Ceylon have set most irregularly. Even on neighbouring estates you see one with a plentiful supply, and the other with a beggarly show. Why is this thus? On the whole excessive moisture is blamed for the probability of a rather poor autumn crop.

COFFEE.—When you ask a friend who has any of this commodity on his estate how it is getting on, he generally asks you if you think tea is going down to 8d. Why he does so, I cannot say, unless he wishes to insinuate that Tea at that limit is about as good as the Best Ceylon Coffee selling at five guineas per cwt.

I hear that SUTTON in the Agras has been sold for something over £9,000—not so dusty a figure!

FOOT-AND MOUTH DISEASE is prevalent in some districts. With careful disinfecting and segregation, this pest can be much minimised.

Labour is plentiful at present, because there is no fasting to speak of. Wait till October and then we will hear a howl. No time should be lost in sending some Government official and a planter of good standing to visit some of the districts suffering from food scarcity in districts probably adjoining the districts we at present get our labour from. Such a commission would cost little, and give us some data to work on.

THE MANUFACTURING INDUSTRIES OF MALABAR.

Malabar is one of the principal Districts where European enterprise is employed in the development of the country. The manufacturing industries there from year to year are increasing with the aid of European capital. During the past official year the Malabar Spinning and Weaving Company continued its operations, employing only 801 hands against 878 in the previous year. The out-turn was 1,183,741 lb. of yarn valued at R4,43,903 against an out-turn of 1,153,900 lb. at R4,87,790 in the preceding year. This is the only factory which comes under the Factory Act, and is subject to the inspection of Government officers. The Basel Mission has weaving establishments at Cannanore, Calicut, Tellicherry and Churubala, which manufactured cotton fabrics to the value of R1,40,737. Messrs Volkart Brothers, of Cochin, and Messrs. Honko & Co., of Calicut manufactured coir-matting to the value of R37,320. This industry is also carried out by Messrs. Pierce Leslie & Co., of Calicut. Coffee curing is carried on by seven European firms in Tellicherry and Calicut. The Basel Mission has a tile factory at Calicut with a branch at Kodacal, near Tirur, at which ten lakhs of tiles were made, of the aggregate value R10,000. Two hundred labourers are employed on these works daily. A Parsee firm, Messrs. Manekji & Co., has a tile factory at the Feroke. Messrs. Henke & Co., are engaged in the manufacture of cigars at Calicut, and turned out cigars to the value of R3,000. Coir and cinchona baling, the preparation of bone manure and bleaching of ginger are also carried on to some extent. Calicut has three soda water manufactories at which 6,220 dozen bottles of water were made valued at R3,252 during the year, against 5,420 dozens in 1888-89.—*M. Mail*, Aug. 14th.

BARK AND DRUG REPORT.

(From the *Chemist and Druggist*.)

London, Aug. 8th.

QUININE.—There is no alteration in the market. Several transactions of secondary importance—said to be mainly for consumption—are reported at 10½ per oz for Fabbrica Lombarda; and 10½ to 10½ per oz for B & S and Brunswick quinine in bulk. Messrs. Hartford, Schoellkopf, and Molagan, of New York, observe, with regard to the position of quinine in the United States:—“Everybody is willing to admit that the foreign statistical position of bark and the unit price paid for assao does not warrant such low prices, 200 being the present New York quotation, but there is no large demand for quinine at present, and hence the decline. In the face of apparently favourable conditions. We take the following figures from the U. S. Government statistics just to hand:—

	Lbs.
Quinine barks imported for 11 months ended May 31st, 1891	2,581,381
1890	2,249,242
Increase	335,139

If we take 8 per cent as a fair average for the quinine contained in the bark, we get, say, 1,500,000 oz of sulphate quinine, but a considerable portion of this bark is used for druggists' purposes, so that we would consider 1,250,000 oz to be about the quantity produced in this country. Next we have

	Oz.
Quinine and its salts imported for 11 months ending May 31st, 1891	3,102,960
1890	2,826,138
Increase	276,822

It will be seen that importations of both bark and quinine are increasing. As cinchonidia and other salts of quinine play minor part now, we conclude that the great bulk of the importations were sulphate of quinine. It will, therefore, be noticed that the imports and production give at least 4,250,000 oz for eleven months, or, say 4,750 oz yearly, for consumption in this country. That there is considerable over-production of quinine we have no doubt, and perhaps this is the true reason why the market has taken a downward course."

ECHOES OF SCIENCE.

The mushroom has become a simile for vigorous growth, and a recent instance of its capacity for thriving in untoward circumstances comes to us from Stockton, California, where several fine specimens were found growing on the concrete floor of a stable. The floor had been laid for a year, and consisted of cement with a top coating of gravel and asphalt. The mushrooms germinated in the body of the concrete, breaking through the cement to reach the air. One grew to a height of one-and-a-half inches, and the diameter of its stem was three fourths of an inch, while its substance was beautifully white and firm. The conjecture is that some mushroom spawn had become mixed up with the concrete when the floor was laid. They were rooted about 1¼ in below the surface, and one of them had cast a fragment of the superincumbent cement about a foot away.

The power of sunlight in promoting the fragrance of flowers has been investigated by Hler Regell, who finds that when a plant is kept in the dark the flowers are scentless. If the flower-buds alone were kept in the dark, the flowers proved to be fragrant. Even flowers which bloom at night lost their scent when the plant was deprived of light. On restoring the light, however, the flowers recovered their scent. Respiration has also an influence on their fragrance. For example a plant of *yceterinia* enclosed, in a bell-jar, with oxygen gas, behaved as it would have done in air, whereas one enclosed with hydrogen did not open its flower-buds, and these had no scent.

M. Bouchon Brandely has introduced a simple device for facilitating the growth of oysters in the French beds. It consists of a series of shallow trays of wire netting, about two feet, square and four inches deep. These are ranged in tiers on iron frames, which are either planted on the bottom or suspended from rafts to a suitable depth. The oysters, being placed in these trays, are easily collected, and are protected from unsuitable soils, or such enemies as borers and "five-fingers," while being exposed on all sides to the free circulation of the water. The apparatus might be useful in the Thames beds where a curious disease accompanied by rotting of the shell has made its appearance.

A new antiseptic called microcidine has been brought to the notice of the French Academy of Medicine by Professor Berlioz of Grenoble. It is a compound of naphthol and soda, neither poisonous nor irritating, and is twenty times as active as boracic acid, while being more soluble than carbolic acid, thymol, and others. Microcidine is a greyish powder, and a solution of three grammes in a litre of water does not stain the hands or bandages. It is particularly well adapted for family use.

M. Deberain, a French chemist, has devised an interesting way of showing that starch is the first stable product of the activity of light and chlorophyll in leaves. It is based on the fact that starch forms a blue colour when in contact with iodine. A growing leaf is covered above and below with black paper, which is quite opaque, by means of gum arabic, the upper foil, having been cut into a stencil plate with letters or figures. This should be done in the early morning, when the leaf is free of starch, that made the day before having

migrated in the night to the internal parts of the plant. After a few hours' exposure to the light the leaf is plucked, the veins removed with warm water, the chlorophyll dissolved out by boiling alcohol, and the bleached leaf steeped in tincture of iodine. The iodine uniting with the starch develops the letters or figures which have been stenciled by the daylight.

VICTORIA COUNTY, NATAL, TEA ESTATES.

"Spectemur Agendo" writes:—Having time to take a stroll round the country, I availed myself of the oft-repeated kind invitations of Mr. W. Hindson to pay a visit to his tea plantations at Nonoti Peak and Clifton, which adjoin, and are within easy ride from Stanger. After passing the Kearsey estate one soon arrives at the Nonoti Peak estate, so called from being situated on the Nonoti River, under the shadow of a hill, the highest in this division, and for this reason selected by the trigonometrical survey party as suitable for fixing a beacon thereon. One cannot help feeling the difference in atmosphere as one leaves the depressing air of Stanger—a most ill-chosen spot for a township—and approaches the salubrious climate of Nonoti Peak, a well-selected spot, facing the sea, and deriving the full benefit of the sea breeze. Our old friend Tom Peachey, the former owner, know what he was about when he pitched upon this spot to settle down upon. All the surroundings bear evidence of the business-like and methodical manner in which the management of this estate is conducted; and if tea planting does not succeed under it, the cause of failure must be looked for elsewhere. Judging from what I saw on this estate and others in the district, I can see no reason why it should not turn out a success. Doubtless, the pioneers in this, as in all other industries, will meet with checks and drawbacks, and will find that methods which suit in other climes may not exactly suit in Natal; but so far things look very promising.—*Natal Mercury.*

THE TEA TRADE OF MACAO is thus reported on by Mr. Consul Joly. It is curious to hear of Chinese tea makers studying the taste of their own countrymen for "highly flavoured" tea:—

Though the quality of the teas during the past season was good—in fact, it is said that they were even better than they have been for some time—there has been again a marked decline in what was once an important staple of export. But what else can be expected when other countries can export a good clean tea at a low cost and no duties? It is, however, gratifying to hear that though small, comparatively, has been the export, the teas of this district have fetched fairly remunerative prices. The total number of chests exported last year seems to have been 157,505, as against 178,220 chests of the previous season. The reduction is striking; in fact, the Chinese themselves find tea business with foreigners so much on the decrease that it suits their interests to make the tea of this district into Pao-shang, a highly-flavoured tea, which is in great demand wherever Chinese settle, in lieu of Congon for foreign countries. Macao teas have, therefore taken their share in the general disaster; but be the causes of the deterioration of the tea trade whatever they may be, it is evident that the reduction of duty at home has not given any impetus to the tea trade in Macao, exposed as that trade is still to careless production, faulty preparation, and last but not least, to the levy of exorbitant duties and *lekin* charges.

CEYLON CACAO.

Ceylon Cacao has taken the place proper to all the products in general of our planters in the London market. It realizes the highest prices there and has distanced most of its rivals. When the first shipments of Ceylon cacao went into Mining Lane, and met with the favourable reception which our readers will remember, a West Indian Cacao planter happened to be visiting the Island, and we had the pleasure of meeting him at a bungalow upcountry. The conversation turning upon the subject of cacao, and the prices the Ceylon article was then obtaining, the stranger inquired, with a somewhat sardonic tone, how long we supposed that sort of thing would last. Failing entirely to understand what he meant, we had to ask what sort of thing he referred to. He, evidently supposing our question to be evasive, said: "Well! to speak plainly, I want to know how long you can afford to ship picked samples and what you mean to do with the bulk of your cacao?" In vain we endeavoured to satisfy him that the shipments were fair, and comprised all the merchantable cacao produced on the estate. He firmly believed and plainly said we could not continue to obtain such prices, and that Ceylon cacao, when fairly exported, would certainly come down to the prices he and others in the West were realizing. We have reason to believe that he retained his scepticism to the end of his short visit. But, happily, Ceylon cacao retains the character and realizes the high prices in which he could not believe.

The secret of the success of the Ceylon product cannot, we think, be attributed to any special virtue in the soils or climates of the estates, but to the care which our abundance of cheap labour enables the planters to observe in the gathering and curing of the beans. The superiority of Ceylon coffee likewise consists in the beautiful hue of the bean, when cured with the skill and care bestowed upon it in the processes of harvesting and curing. Colour, as an indication of the preservation of the best inherent qualities of the Coffee, was always a special criterion of its market value, and justly so, as that characteristic can only be retained by the most careful and skilful treatment in preparation. In like manner, the bright brick-red colour of the cacao bean, we presume must have been found in practice to indicate certain inherent qualities that have been carefully retained in the process of curing. It will be remembered, by some at least of our Ceylon cacao planters, that they were taught by instructions from their elders in the West to impart that test colour artificially. The practice there, we were told, is to give the colour by means of a kind of clay, but that sort of expedient was not approved by planters here, and fortunately it has not been found necessary. According to the letter we published yesterday, from a cacao planter who writes from London, the colour of the beans is still held as a criterion of the quantity of the article, and largely influences its value. This being so, it is probable that the brightness of the colour outside of the skin may indicate a richness of the chocolate colour and quality of the beans within.

The cultivation of cacao has not progressed so rapidly here as might have been expected of a new product, undertaken as it was, at a time when planters were urgently in need of a substitute for the old staple, that had just shown unmistakably that its decline was beyond redemption. Cacao had, almost at its outset, to contend against *Helopeltis*, which had a gained a destructive force before the cause of damage had been discovered. Thrips also attacked the enterprise, and it therefore made its debut in the face of very inimical forces. Nevertheless, the cultivation is reviving, and will continue to extend wherever suitable soil and climate favour its growth. We fully expect that it will accompany the now enterprise in Tobacco, which requires soil of a character similar to that in which cacao thrives best. Tobacco will not succeed on the same ground, year after year, without some rest, or rotation, and it will therefore need to have adjuncts such as cotton and cacao, which require similar conditions, and are less exacting in the matter of soil.—Local "Independent."

TOBACCO CULTIVATION IN BATTICALOA.

Sir.—Tobacco cultivation was introduced into this district, in the time of the Dutch Government, by some people from Jaffna belonging to the "Tannakura" class. At that time small gardens only were cultivated, but later on, in the time of the English more gardens were opened. During the administration of this district, by the late Messrs. Bone and Atherton, large numbers of tobacco cultivators came from Jaffna, belonging to the class referred to, and settled in the North and South of Batticaloa, and carried on tobacco cultivation; but it was until the time of the late Mr. Birch that tobacco was more extensively cultivated here. Crown lands were surveyed and sold in small lots, thus bringing within the reach of every one the possession of a few acres of land. Those lots were bought up, and the higher portions of it were planted with tobacco and the lower portions converted into paddy fields. Ever since that period up to the present it has been cultivated very largely, and those people, who are deprived of chenas, betake themselves to this industry, as it is paying well; better than paddy cultivation in these hard times. We hope that the day is not far distant when tobacco and other products such as betel leaves, pepper, aracanats &c. will supersede paddy.

Jaffna tobacco is preferred to what Batticaloa produces, on account of its flavour, which is deficient in the latter. The growers of the weed say, that the different kinds of manure used in the gardens make all the difference. For in Jaffna goat and sheep manure is used, as a rule; but, here the plantation is manured by black cattle and buffaloes owing to the want of an abundance of goat and sheep for the purpose, which are rather scanty in the district. At present, the best tobacco is grown at Chenket-addy and Maradey, in the north; and at Chenget-pudde and Torendamedo, in the south Batticaloa. If small patches of Crown land, not suitable for other products, are given to the inhabitants on easier terms, than what is now the case, much more land will be converted into tobacco gardens which will ultimately give the means of living and lodging to many a poor man. This will, in fact, form a new colony of settlers.

For instance, here in Batticaloa, a poor man not a "Pody," with his small savings buys $\frac{1}{4}$ of an acre of land, at the Government sale, cuts, clears and improves it by planting a few coconut plants, and after some years of toil and labor, this, once a jungle, now serves as the house and hearth of himself and his family. It will be so, if the Government will hold out sufficient encouragement to tobacco growers.

In connection with this subject, I should mention that a scion of the family of tobacco cultivators, who first settled in Batticaloa, in the time of the Dutch, died to-day in his ninety-first year, leaving behind a large number of relatives. He was known as "Counter Benjamin Motto." He was employed in the Kachecheri, as treasury watcher, for many years, and retired lately on a well-earned pension.

A VICTORIAN ORANGERY.

By BRUNI.

Over thirty years ago there journeyed out into the wild forest that then covered a wide expanse to the westward of the town of Wangaratta a man hailing from the Parramatta district of New South Wales, who was looking for a piece of land on which he might form a home. It was a singular journey to take, for the appearance of the country was anything but inviting, the soil being cold and poor, and the surface was covered with forest of indifferent timber, below which was a heavy undergrowth. At that time there were large areas of fertile land open for selection in almost every part of the north-east district. This man, by name James Brien, halted not till he reached a small watercourse close to where the northern end of the Warby Range sinks into the plain. At the present day the spot where

Mr. Brien fixed his camp, and where his horse now stands, has little to attract either the grazier or the agriculturist, but when he made his selection he had some trouble in clearing away the saplings so that he might use the cover of his waggon as a tent. Coming from a land where orange-growing was extensively practised, and where he has many relations still engaged in the industry, he naturally cast about for a spot that was suitable for an orangery, and he found it. Close to his first camp he discovered a little plot of land (not more than eight acres) lying in a dell at the foot of the range which, in his opinion, was admirably suited for an orangery. As soon as he got the land prepared he commenced planting oranges, and at the present day that little nook at the foot of those ranges of evil repute is worth more money and will give a much better return than many a half-section farm of fertile soil in what are regarded as more favoured localities.

The road out from Wangaratta to Mr. J. Brien's orangery is none of the best in summer, and in winter it must be anything but a pleasant drive. For some distance out from the town the soil is excellent either for pasture or agriculture, a chocolate soil of great depth, and capable of being worked at almost any time of the year. I have often thought the soil would prove well adapted for growing lucerne but not a plot of this fodder plant could I see. On making inquiry I was shown a field that was sown with lucerne about ten or a dozen years ago, and my informant said that it grew remarkably well. It was gradually got out of the land by growing a succession of grain crops. After journeying about two miles the surface began to show a very slight rise towards the hills, and with this rise in the surface there came a falling-off in the quality of the soil. The nearer we got to the foot of the range the more pronounced became the rise, and the more indifferent the soil. At last, when near the hills, we met with patches of almost pure sand, and that sure indication of a cold, poor soil—the grass tree—was plentiful. It was what bushmen call sour, hungry country, that is generally regarded as useless for either the husbandman or the agriculturist. About Mr. Brien's steading there was a slight improvement in the character of the soil.

There was nothing about the homestead to distinguish it from many hundreds of other old Victorian farm-houses—a rambling collection of buildings, many of which appeared to be suffering from the decrepitude of old age. The house "did keep itself," so, after admiring the handsome pea-fowl and flocks of Guinea fowl, we made our way to the orangery. For sometime we saw nothing but the melancholy aspect of a poor-soil farm, with the dreary forest on three sides and steep range on the other. Where a small watercourse runs down from the hills there is a little valley, almost hemmed in by the foot of the range, and looking towards this recess I saw the dark-green foliage of the orange trees, that appeared almost black in comparison with the dull green of the surrounding gum trees. As we drew nearer I could see the more advanced fruit just beginning to take a tinge of yellow. The main crop is, however, still of a deep green colour, and will not be ready for picking till about July.

This orangery contains about eight hundred trees, of which three hundred are of large size and bear immense crops. I have often heard instances of the wonderful fecundity of the orange tree, but even after going through the ground and taking a good look at the finest trees, I was greatly surprised to learn what immense crops of fruit they yield. On asking Mr. Brien what would be a good crop from one of his old trees, he told me that it would be between six and seven hundred dozen oranges. The fruit is of excellent quality, and finds ready purchasers in the district and in the metropolis. For many years the market price was 1s. per dozen, but now it is about 9d. per dozen, a price at which the grower makes a very handsome profit. A great many varieties of the fruit are grown, and, as a rule, they give excellent yields. The navel orange is, however, an

exception, and the blood orange is not a favourite with Mr. Brien. They produce very fine fruit, but they are not heavy croppers in this district. One of the greatest peculiarities in this orangery is a tree that yields fruit which has the appearance of having had the quarters split open when small, and over the whole there is the ordinary rind. This tree always produces some fruit thus curiously misshapen, but this year there are an unusual number of distorted oranges. The tree is large, handsome, and healthy, and the normal fruit is plentiful and of good size and flavour.

Experts who have more or less experience of the Californian oranges say that irrigation is necessary for the successful cultivation of the orange, but in Mr. Brien's orangery one may see large and handsome trees growing heavy crops of excellent fruit, and yet, they never receive any water but the rainfall. Mr. Brien has a great objection to irrigating his trees, being of opinion that the result would be a loss. By irrigation he says the trees would make a luxuriant growth, and the fruit would be coarse and flavourless. So far from irrigation being required, he points out that his best trees are in the driest spots. The difference is very marked in the young trees. Along the small water-course, which has cut a channel fully 10ft. deep, there is a small bank from which the surface falls away from the creek, and near this bank the orange trees have made excellent progress, while those situated in the lower ground are scarcely half the size. The soil does not give the idea that it would hold wet sufficiently to be harmful, being a free, deep loam, but in a few of the lowest spots the trees are evidently decaying. This Mr. Brien attributes entirely to the influence of damp. The orange is, apparently, a capricious tree, and in spot where one fades away it is almost useless to attempt to grow another. Mr. Brien is an enthusiastic cultivator of the orange, and every year he takes a trip through the orange groves of Parramatta to keep himself posted up in all that relates to the advancement of the industry.

Outside the orange grove the soil alters rapidly, but it is evidently well adapted for growing fruit trees. There is a good-sized belt of orchard on two sides of the orangery, and already the trees, though young, are producing large quantities of excellent fruit. The peaches grown in this orchard command high prices, and the sample I saw of the apples was highly creditable. The orchard and orangery are admirably cultivated, and not a weed is to be seen anywhere. The fruit trees are well cared for, but the orange trees are, as they deserve to be, first in Mr. Brien's thoughts. To him they are more than trees, and he speaks of them as living, sentient beings, having affections and antipathies, while the fruit trees, though worthy of being carefully tended, are merely trees. Mr. Brien has a good-sized holding; he keeps a flock of about 1,400 sheep, and does some farming, but the whole interest of the place is centred in a little plot of land scarcely as large as many a Toorak property, which is probably more valuable than the rest of the farm twice told. It was a strange chance that led the wanderer's steps through forest and scrub to this priceless gem of land, and that he should have the skill and enterprise to develop its utmost capabilities.—*Australasian*.

water. It grows very vigorously under these conditions in large tufts, like "Tussock" grass, and the thickest of the stalks are of the same size as a Malacca cane. It grows equally well in running or standing water, and is called by the Natives of the Northern part of the Eastern province, "*The Coile Colle*." The taste is rather plain and insipid, but in admixture with condiments of various kinds it makes a very passable curry. I once tried it plain boiled with pepper and salt as vegetable to accompany meat; but did not much care to repeat the experiment! Made into what Tamils call "chndel" (a dry curry) it is not at all bad, and is said to be good in fevers and sometimes in stomach complaints. It is brought to market in prettily tied bundles—just as celery is tried up for the markets in England—and is eagerly bought up by the frequenters of the bazaars in town where it is a rarity, and even a luxury. It cannot be had nearer than 12 or 15 miles from town, where it grows in great profusion on the banks of the old Dutch canal at a village called Vandaramulle. I believe it is well known in all Sinhalese districts near the sea, such as Negombo and towards Puttalam, whereas at Batticaloa it grows on the borders of the canal, and the estuaries or marshes near the canal between Negombo and Puttalam. There are one or two Sinhalese men who have established themselves as traders or boutique-keepers in the villages of the Northern part of the Eastern Province, and when either business or inclination leads them into town they rarely fail to bring in a large supply of coile colle. The gathering of it is now and then attended with danger, as on one occasion a poor old Sinhalese man was caught and dragged into the sluggish waters of the canal by a crocodile, and nothing more was ever seen or heard of him.

Coile colle is said to be plentiful at Bentota, Kalutara, Tangalla and Matara, as well as at Ratnapura; but in all my wanderings over the Island, I have seen it exposed for sale only at Batticaloa.

REGINALD ARMOUR.

—Local "Examiner."

CINNAMON SALES.

Fuller information, to hand by the last Mail, of the Quarterly Sales of Cinnamon in May, does not materially affect the conclusions we had drawn from the Telegraphic Summary which came to hand on the 26th ultimo. Little more than one-third of the moderate quantity of spice offered—1,328 bales against 1,582 in February, and 1,351 in May 1890—found buyers. The attendance of bidders was small, competition was slack, and prices generally ruled in favour of the buyers. The commoner qualities sold at a slight advance, but the demand even for those was indifferent, and all parcels offered were not taken up. The extent to which the finer qualities were neglected, cannot be realised without a careful study of the Sale Lists. Not only had lower prices to be accepted for them, but, as we surmised had been the case when we wrote on the subject last month, the demand even at these reduced prices was not sufficient to clear the offerings. Thus, of 101 Bales of F. S. W. S., only three Bales found buyers at a fall of 3d. to 1s. Of 78 bales F. S. K. not one found a buyer. So with J. D. S. R. of which there were 40 bales offered. Of 96 Bales S. D. A. R. Cinnamon, only 10 Bales of the coarsest were sold. Of 23 bales E. B. Franklands, only 8 bales were sold. No less than 305 Bales of G. De C. were offered, but only 31 of the coarsest sorts sold. These are some of the more prominent brands, whose shipments were neglected. It was the same with other well-known marks, whose make is of medium qualities. Only a fraction found buyers, resulting, as we said, in little more than one-third of the total quantity of all grades offered at the sale passing the hammer. The only mark for which there was anything like competition, and which sold at or about previous prices, was the leading brand

THE COILE COLLE—A FERN USED AS FOOD BY THE CEYLON VILLAGER.

By the margins of many water gullies, tanks and canals in Ceylon, grows a sort of graceful tall fern, the extreme tops of which are of an amerald green tint, while lower down they become coarse, rank and of a bluish green or in some cases olive hue. The whole stalk looks very like a large stalk of celery, and the foliage is of the same curly or wrinkled nature. It does not grow only on wet or marshy soil; but it is necessary to its well doing and growth, that its roots should literally stand in

A. S. G. P. The Cinnamon from the Golapokuna Estate has long topped the market; and the explanation of the demand for it having continued, while the trade generally was averse from the first qualities of Spice, is that it has been a favourite in Spain, and that a large buyer always laid in a heavy stock for the Spanish Market. Taking advantage of the fall in prices, another, generally small buyer, wished to possess himself of a large quantity of the finely prepared spice. The old buyer—fearing that the effect of such a purchase would be that he would be undersold, and that his constituents would have their favourite spice at less than the price which they had always been ready to pay—thus resulting in a loss to himself on the large stocks we had already secured at advanced prices—entered keenly into the competition. Hence the realisation of old prices. Whatever the cause, the result is satisfactory to the proprietors of Golapokuna. At least, they have fared better than the owners of other Estates whose spice found no buyers.

It is very clear that the principal buyers have set their faces against the more expensive makes of Cinnamon, and that the manufacturers of the finer qualities must be prepared to accept even lower rates than had obtained during the past few years. But how is this change to be accounted for? It has been said, and no doubt with truth, that consumers have probably found that the coarser qualities would serve sufficiently well for most purposes; but how has this feeling been brought about? Chiefly, we think, through the direct importations of the coarsest qualities into the Continental markets, since the opening of the Suez Canal. So long as the Cape route was inevitable, London maintained its supremacy as the emporium of the world, without question. It doubtless holds the same position yet; but with this difference—that other centres attract a far larger volume of trade than they had hitherto done. Thus, even so late as 1889-91 of 1,796,372 lb. of cinnamon in Bales exported hence, no less than 1,510,879 lb. reached London, the remainder or less than one-sixth, having been distributed throughout the world. Last year, of 1,894,514 lb. exported, only 1,084,837 lb. found their way to London, the rest, or nearly a half, having been shipped direct to other markets, chiefly Continental. This year, up to date, of 773,848 lb. shipped, 432,098 went to the United Kingdom, the rest, or nearly a half, having gone to other ports. Now, the effect of this redistribution of produce has been to place within the reach of consumers the coarser qualities of bark at the cheapest rates at which Continental Firms established here could supply them. London Buyers would thus be at a disadvantage; and the really finer quality of spice—which is all shipped to the United Kingdom, and which they secure for their constituents elsewhere—is not held to be sufficient to explain the difference in price between purchases on the spot, and purchases through London. We believe it is the demand for lower prices from their constituents which has led to the drop which we are now considering, and which has compelled London Firms to advise their Ceylon Principals to devote themselves chiefly to medium makes at a reduced cost of manufacture. And this view of the influence of the shifting of markets, as explaining both the fall in price and the slack demand for all qualities, is confirmed by the good statistical position of Cinnamon in London which Agents report. If the shipments are not disposed of as fast as they arrive, there should be an accumulation of stocks—assuming the imports to remain the same—instead of favourable stocks as at present reported. It is greatly to be feared that the advice, at least as regards reduced rates, will fall on deaf ears, as Cinnamon Planters, depending as they do on men of a particular caste to harvest their bark, do not find themselves strong enough to combine to reduce rates. The only remedy we can see is to ship the best qualities to the chief Continental markets. Who will inaugurate a Cinnamon Fund Committee, on the lines of the Tea Fund Committee?—Local "Examiner."

THE ORANGE BLOSSOM is one of the most delicate of flowers; its very mission is of a tender nature, and yet its great helpmate in exportation is the potato. Since the exportation of the flowers from California has become a large trade, it has been found that the best method of preserving the orange blossom is to push the stem into a potato. This method might be employed for flowers in table decoration, but if considered more artistic, the potato should be hidden from the vulgar gaze. —*Port-of-Spain Gazette.*

EARLY TEA DRINKING is thus noticed in the *American Grocer*:—

In the early days of New England, tea and coffee checked the use of alcoholic drinks. Weeden, in his economic history of New England, in alluding to tea, says that "in this little Chinese leaf was folded the gem which enlarged into American Independence." As early as May, 1714, one Edward Mill, Sudbury street, Boston, advertised, "very fine green tea, the best for color and taste." In 1718 the historians at Lynn state that it was "little used." When the fair dames went for a gossip and drinking, each carried her own tea cup—very small—with saucer and spoon. The following old English letter shows that tea drinking was a matter of comment as late as 1740. "They are not much esteemed now that will not treat high and gossip about. Tea has now become the darling of our women. Almost every little tradesman's wife must sit sipping tea for an hour or more in a morning, and it may be again in the afternoon, if they can get it and nothing will please them to sip it out of but chinaware, if they can get it. They talk of bestowing 30 or 40 shillings upon a tea equipage, as they call it. There is the silver spoon, silver tongs, and many other trinkets that I cannot name."

Tea-parties gradually established themselves after this. It is related of a bachelor tutor at Harvard, that when his hostess asked him if he would have tea strong or weak, he answered: "*Strong of the tea, strong of the sugar, and strong of the cream.*"

TIMBER FOR TEA ESTATES.—On this subject Mr. Le Mesurier has the following remarks in his official diary for 1890:—

Government must, I think, supply the wood, or the tea enterprise would be seriously crippled in many places; and the best method to adopt, as I think (1) to have central depots to supply estates that are at a distance from any Government forest, and to issue firewood at rates that will give a good profit, sufficient, that is, to cover all expenses of cutting, transport, supervision &c. and a royalty of say Rs 1 per yard. (2) To survey all the Crown forests, bordering estates, into small blocks of say, five acres each; to calculate the value of all the firewood—*i. e.*, all the timber that is not fit for timber purposes—in each block, say Rs 1 per cubic foot, and to sell the right to cut this firewood at the estimated value to such estates in the neighbourhood as wish to take it, no estate being allowed more than one block at a time, and only a certain acreage per annum proportionate to the extent of its own cultivated acreage; each block to be completely cleared of all but the timber trees, which should be carefully marked by the Forest Department and left untouched (except by themselves, should they require timber), before any new block is taken up; and as each block is cleared it should be replanted by the Forest Department. Any infringement of the conditions of the permit to cut to be liable to a cancellation of the permit and a refusal to allow any more to be cut. Government would thus get the value of the wood and the planter his firewood with the smallest amount of interference, which is the great thing to aim at in this matter; and there would be little danger of cheating. The withdrawal of a permit would be such a serious matter to him that the planter would take care that the conditions of the license were carefully observed. The blocks being replanted by the Forest Department as soon as they were cleared would provide year by year a reserve of wood to replace what was taken away.

LONDON TEA RETURNS FOR SEVEN MONTHS.

The imports of China tea between January 1st and July 31st was 27,654,000 lb. against 29,050 in the similar period of 1890. Java showed 2,698,000 against 2,371,000. Ceylon indicated the large increase of 35,707,000 against 24,941. Ceylon imports for the seven months of this year, indeed, ran India very close with its import of only 37,793 against 38,126,000 the previous year. But when we come to deliveries, Ceylon is left very far behind India. The figures for our tea are 28,642,000, a good increase on 20,824,000 in the seven months of 1890. But in the case of India, although there was a falling off from 59,731,000 in 1890 to 55,578,000, yet of this latter quantity a large proportion was taken from stocks which showed only 18,594,000 against so much as 16,283,000 for Ceylon. Indian stocks had gone up only 2½ millions from 16,030,000 in 1890, while Ceylon had increased from 10,880,000 or nearly 5½ millions. We can only hope that stocks of Ceylon will soon be worked off. The brokers' reports are impartial in recognizing the poor quality of Indian as well as Ceylon tea. The deliveries of China were 43,875,000 against 50,647,000, while stocks of this kind had gone down from 36,218,000, to 28,592,000.

The deliveries of Java tea had increased from 2,614,000 to 2,580,000 lb., and stocks of this kind were reduced from 903,000 to 877,000. An increase of 2 millions of pounds in the stock of Indian teas, has little significance, but an increase of 5½ millions in stocks of Ceylon is calculated to give our planters concern. The imports of the four kinds were 103,847,000 against 94,488,000, while deliveries were only 130,675,000 against 132,716,000 in the seven months of 1890. The deliveries of Ceylon tea for the seven months had been on an average a little over 4 millions per mensem. The same rate for the rest of the year would make a total of only 48 millions, while our total exports are estimated at 60 millions up to 70. Let us hope that an increased demand not only in the British but in other markets may come to the aid of our enterprise. We can, we suppose, calculate on the Australian and other markets taking 5 millions of pounds. But the Tea Fund Committee, clearly, must not relax its efforts.

REDUCTION OF THE EXPORT DUTY ON CINCHONA BARK.

A proclamation in today's *Gazette* states that the Governor, with the advice of the Executive Council, for the purposes of the "Medical Wants Ordinance, 1880, Amendments Ordinance, 1882," reduces the duty upon cinchona of twenty cents per cwt. to a duty of five cents per cwt., which last mentioned duty is imposed as the duty upon all cinchona entered for exportation at any port in this Colony as from and after the first day of September 1891.

AN INDIAN TODDY PALM—PHOENIX SYLVESTRIS.

A familiar and perhaps, to some people, a monotonous feature in Indian scenery, particularly along the coast regions of Western India, are the groves of Phoenix sylvestris, one of the toddy Palms, the commonest of the wild Palms of the country, but a most valuable one to the natives. It is frequently seen in company with another noble Palm, *Borassus flabelliformis*, the Palmyra, and these, together with the Coconut Palm, which, in the neighbourhood of

Bombay, is cultivated in extensive plantations, comprise the chief elements of that striking tropical scenery which always impresses travellers from northern regions when they first see it. This Phoenix does not differ materially in aspect from the Date Palm of Egypt, *P. dactylifera*, which one sees on the way out; and my impression that the Date Palm, as well as such Phoenixes as *P. rapicola*, *feculis*, *acaulis*, *canariensis*, and possibly others, are but geographical forms of a widely distributed species, having a range almost as extensive as that of the Coconut Palm, is thus as it may, they all seem to me very much alike, and from my point of view produce the same effect, for in a natural grove of *P. sylvestris* one could select forms that to all appearances are identical with the species named. The Palm now illustrated is not the only one that yields toddy, as there are several in India from which the enticing juice can be drawn, notably the Palmyra, Coconut and Wine Palm (*Caryota urens*), but in Guzerat the Phoenix yields the bulk of the enormous quantity of toddy that is consumed by the natives. Toddy drawing is, in fact, an important industry, and moreover a source of revenue to the Government, as a tax is imposed upon every tree in full yield, and to which an official number is attached. A large plantation of Phoenix is a valuable property, for the owners assess their value at from five to fifteen rupees a tree. If a plantation is near a town or group of villages, or near a frequented highway, the drawing and distribution of toddy is always active, and keeps several people busy. The mode of drawing is admirably shown in the picture. The toddy man is in the act of fixing a "chattie" at the mouth of a notch that has previously been made in the succulent part of the stem, the incision being made so that the descending sap trickles into the vessel, a few strips of reed being placed so as to conduct the juice more readily. The chatties are emptied morning and evening, and as they hold a quart or more, a great quantity of sap is extracted from each tree during the season; and the loss tells materially on the health of the tree, so much so that if the extraction were to continue year after year, the trees would soon die from exhaustion. After a tree has been tapped for a full season, it is allowed to rest for two or three seasons, and that accounts for the intervals of the scars on the trunk, as may be seen in the picture where the man has his left foot and the scar lower down. The toddy drawer is possessed of surprising agility in climbing the perpendicular stems, which he does with the utmost ease, the only support being the rope he has fastened round his waist, which leaves his hands free. The fluid thus obtained is of the consistence of watered milk, and has a sweetish, and to some Europeans an agreeable taste, while to others it is nauseating. When freshly drawn it is most refreshing, and to quaff a bowl of it when excessively thirsty is one of the pleasantest incidents in Indian life. When, however, it is allowed to ferment, which it quickly does, it is sour and unpleasant, and becomes as intoxicating as Scotch nootah but in this state it obviously finds more favour with the natives. As a garden plant, the wild Phoenix is of great value for landscape effect when it occurs in natural groups, for in these you see all gradations of size, from the small seedling to the decrepit old trees, that have reached the length of their days, and lean leeward in a most picturesque way. The bluish-grey-green tint of a grove of Phoenix is perhaps too sombre, but in a garden one can always introduce variety as a foreground, or intermixed in the group. It is a singular fact that the Date-bearing Palms do not thrive successfully in India, so as to produce edible fruit, and that of *P. Sylvestris* is valueless as food, though the leaves and stems, and the fibre and bark thereof, are of value to the natives in various ways. The engraving (fig. 14) is an admirable reproduction of a photograph by Messrs. Johnson & Hoffman, of Calcutta. W. GORDON.—*Gardener's Chronicle*. [In the case of all the toddy plants of Ceylon,—coconut palm, kital and palmyra, the juice is obtained from the unopened flower: spathe,—never from the stem.—Ed. T. A.]

CACAO: JAVA GOING AHEAD?

A correspondent writes:—

"In case you may not have seen it I enclose a special cacao report, suited for the West Indian mail, for your perusal and return. You will notice how Ceylon kinds stand out in the price list, but I hear from home that Javas are to run us very close for both quality and cure." From the report, which is dated August 4th, we quote as follows:—

LEWIS & NOYES' SPECIAL COCOA REPORT FOR THE WEST INDIES & Co.

London, 14, Mincing Lane, Aug. 4th, 1891.

The official figures of the United Kingdom and France for the first six months of the year show a steady and satisfactory increase in the consumption of the article. Other European countries, and the United States, although official data are not available, seem to be moving in the right direction, judging from the out-put of their manufacturers.

So far as supplies are concerned, advices point to satisfactory crops from Trinidad, Grenada, and other West India Islands, although the shipments from the former place are short for the first six months of this year. Guayaquil will undoubtedly furnish less than last year, that crop having been exceptionally heavy. Bahia promises a full crop. The quantity of African shipped is continually increasing and owing to the annual crises in Portugal, which has hitherto received the bulk of the crop, it will be largely diverted to this country.

The increase in the French stock seems chiefly due to the quantity of British West India sent there, whence having prevented orders coming to this market, to compete with our manufacturers, a large proportion is ultimately sent here to be disposed of, this being the chief consuming country for West India kinds. We are of opinion that were the whole of the Trinidad, Grenada, &c. shipped to Europe, sent to this port, instead of being divided as at present, a much higher range of prices would be obtained for shippers' account. The exceptionally high prices paid for Ceylon Cocoa, which have existed so long, are largely attributable to the fact that the crop is almost entirely sent to this market where it creates keen competition from all consuming countries as well as our own manufacturers.

The stock in France notwithstanding the short shipments from Trinidad and Guayaquil to date is 1,700 tons larger than last year, the reduction of 300 tons in the United Kingdom stocks making the excess for the two countries 1,400 tons. The advance of 2s to 3s in prices during the early part of the season in Trinidad, Grenada and similar kinds, was largely due to speculative buying, but the fact that stocks show no diminution, and that future supplies are unlikely to fall off, have had the effect of causing the improvements to be lost. With regard to prices of Guayaquil, the increased demand especially for Arriba, and the shorter supply, have caused prices to advance rapidly, and they are now relatively much above the prices of other descriptions.

PRUNING CACAO.—There is an article on this subject in the *Trinidad Agricultural Record* which we have marked for the *Tropical Agriculturist*. The concluding paragraph runs thus:—"Good manxins for the cultivator are,—'prune little, but prune often; prune carefully, but prune with decision. Prune for leaves and a crop must come.'"

LONDON TEA SALE PRICES AND THE RATE OF EXCHANGE.

From the local "Times" we quote the following:— At the request of a correspondent, we have compiled a table showing the weekly averages obtained for Ceylon tea this year and last year, together with the rates of exchange ruling at each period. The table will bear very close and careful examination, as many curious facts can be elucidated from it. For instance, it is plain that the lower rate of exchange which has ruled this year has almost entirely compensated for the fall which has taken place in the tea average:—

TEA TOPICS.

The report of the Committee of the London Wholesale Teedealers' Association, which will be found in another column, is, according to the *Grocer*, of importance to grocers, as a glance at the subjects dealt with during the past year will prove. In the first place, the attempt made by the Customs authorities to have tea weighed to the half-pound, instead of the pound, was successfully resisted by the prompt and energetic action of the Committee, who must have experienced great trouble and given much labour in connection with the various public meetings which were convened at the time the subject was under consideration. If the Customs had gained their point, it would have entailed a serious loss to grocers, for, taking chests, half-chests, and boxes of tea as averaging 50 lb. each with a loss of half-pound on the gross, and a further loss on the tare, making a pound in each package, it would have amounted to 2 per cent in all which our readers can ill afford to lose in these days of extreme competition. Another important subject is the improper

condition in which some packages of tea have been left after inspection. This, no doubt, is owing to the pressure of work consequent upon the anxiety of merchants to put their teas on the market too soon after arrival, not leaving the warehouse properties sufficient time to finish up one parcel before the next is put on show; and, as the merchant's interest ceases directly tea is sold, he can hardly be expected to look very carefully after the condition of the packages when the ownership has passed out of his hands. At the same time, the warehouse proprietor—who is paid for the careful storage of the tea—ought to be careful to see that this being a sensitive article, should not be exposed to the air and fog a moment longer than absolutely necessary.

The question of railway rates has properly engaged the attention of the Committee, and the Honorary Secretary of the Association has been in almost daily attendance at the House of Commons, waiting to give evidence, in conjunction with Mr. Gore (to whom the trade are much indebted for the immense amount of time and thought he has bestowed upon this subject.) To us it is a matter of surprise to find so much upbraid shown by traders, and the very little resistance they have made against the proposed charges of the railway companies. As regards tea, there can be no reason why it should be placed in a higher class than coffee; and in reference to small consignments the proposal of the railway companies is most unjust, and it becomes law the carriage accounts of grocers will be enormously increased without any reason. It is not too late to oppose the Bills in the House of Commons, and we would again urge our readers to stir themselves and take a more lively interest in resisting the railway companies' proposals. The thanks of the trade are due to the Committee of the London Wholesale Dealers' Association for their successful labours during the past year, and we are glad to have this opportunity of expressing, on behalf of grocers, their appreciation of the efforts the Committee have taken to protect their interests in respect to the subjects we have indicated.—*Indian Planters' Gazette.*

LONDON TEA LETTER.

The highest price realized during the week by any Indian Tea was 1s 11½d for 13 chests Broken Orange Pekoo from The Assam Frontier Tea Co. The highest price realized by any Ceylon Tea (bar the two little fancy lots referred to below) was 1s 8½d for 18 half-chests Broken Pekoo from Glassaugh. The two fancy lots, were:—

Two Boxes, Silver Tip, containing 5lb each, net, from Beaumont, one package, Golden Tip, containing three boxes, of 5lb. each, net, from Salaw. The former was "taken out," at 4s 6d the latter was also withdrawn, at 5s per lb.

Ceylon, not content with touching one extremity of the scale of prices, has this week touched the other; not with a few lb. of accidentally spoiled Tea, but with no less than 80 half-chests of Pekoo Panungs, which realized 2½d per lb. This triumph has not yet been signalled by the usual Illustrated Advertisements.

Overheard this week. Scene, a Merchant's Office. Person, A Ceylon Planter—An ex Indian Planter, but unknown to the former as being an old Indian. A merchant. *Ceylon Planter* lay. after a night of fireworks illustrating Ceylon Planters' methods of manufacture: "But then you know Ceylon Planters are a long way ahead of Indian Planters."

Merchant, "In what way?"
Ceylon Planter, "Why in intelligence, and everything else. It stands to reason." Then confidently "They had all the Indian planters' experience, and now have their own, plus superior intelligence. Begaa, where Indian planters left off; don't you know?"

Merchant, "Oh! yes, of course; I see."
Ex-Indian Planter, quietly, "I have always heard that the proof of the pudding is in the eating; it always struck me as strange that such adopts at advertising as the Ceylon planters, should leave the world in the dark

as to the dividends their estates pay, as compared with Indian Companies. But a few days ago I was informed that if anyone went to Ceylon and advertised that they were about to form a new Company, and requested offers of tea estates for incorporation therein, they would receive by return of post, offers of 90 per cent of the estates on the island! Indian planters have a partiality in favour of dividends. Any little vanity they may possess, finds its vent in comparisons of dividends, rather than in profitless comparisons of profitless intelligence. Good afternoon."

I hear that Ceylon planters, as a rule, still perpetuate the old custom, which was once the practice on some gardens in India, of partially rolling first, and then completing the roll, after other batches of leaf have been partially rolled. It would be interesting to get at the truth of the origin, and the cause of the continuance of this practice in Ceylon. I understood from my informant, that it is quite a regulation proceeding, and he spoke of it as though to change it, and roll each charge straight off, were not to be thought of. So presumably they think it desirable in the interest of quality! So far as I know, it arose in India, not with any idea of its being necessary at all, but because, many gardens in those days had rollers of different types, and one roller produced a better twist than the other; but not being able to do all the work by itself, the other roller was employed to partially roll the leaf, which was then finished in the one which produced the better twist. Can it be that those Indian planters who went to Ceylon, (may it be said—to instruct the Ceylon men—) took the custom with them, and that it is now in consequence the orthodox thing to do in Ceylon? It is about as risky a proceeding—especially to leave to a native—as one could invent, and as it cannot of itself improve the quality of the liquor, upon any known theory, it seems to be a superfluous amount of trouble and anxiety, and risk, for some merely imaginary gain. Without great care and attention it spells—"dull in the end."

PERIPATETIC PLANTER.

—*Indian Planters' Gazette.*

[If may do Ceylon planters good to study such hostile criticism as the above. But who did our enterprize the bad turn of sending the 2½d fan- nings to the London Market?—Ed. T. A.]

THE MOON AND THE WEATHER.

(By an Astronomical Correspondent.)

The folk-lore of old times comes down to us from a simple people who but rarely moved away from the place in which they were born, and who, as regards this subject, scarcely suspected that "other parts" simultaneously experienced other weather than that which the convenient moon provided for themselves. It is, therefore, very marvellous, that, in these days of constant movement and easy means of travel, that old moon-lore should have survived, and be still so deep-rooted amongst all classes of the people, and not alone with the simple peasantry of every country. But so it is. So much so, indeed, that even among philosophers one now and then springs up to do battle for the moon, unabashed by the almost silent scepticism of the leading scientific teachers of the present time. Except in occasional passing notes, the "moon and the weather" is seldom referred to at all by the present generation of scientific men, who, so far as they are concerned, consider the subject sufficiently settled by their predecessors. The "Meteorological Society" of our day, too, would not ignore so large a following if it could find reliable data to feed them with; but not only does this Society fail to make use of the moon for prognosticating the weather, but as a writer in *Knowledge* said, not long ago: "On my complaining to the Society that not one in twenty of the forecasts is

correct, as applied to us, the Secretary replied: 'If I could tell how to cast the weather for every subdivision of the kingdom I should be very clever, as, of course, the climates vary in different districts from local causes.' As you sir, say [*i. e.*, R. A. Proctor], 'these daily forecasts are not to be depended upon, and are apparently only a matter of guess work, and so had better be dropped, as, for reference and utility, they are proved to be utterly worthless.'" To this another writer (Captain Noble, a leading astronomer of our day), adds: "If we are satisfied with the return which the British nation receives for the annual sum of £15,000 expended on so called 'Meteorology,' we must—like the Scotchman in the parable,—be *vera thankful* for sma' mairicis." The Society's forecasts were deduced from daily telegraphic reports received from all parts of England and the Continent—data which no private individual could ever hope to collect, and yet, their labour was all in vain!

Notwithstanding all this, however, the popular belief in the moon's control of the weather dies hard, and now and then an effort is made by a competent authority to instruct the public on this abiding superstition. Such a paper has only just fallen into my hands, though published, I believe, a year or two ago. It is written by Mr. John Westwood Oliver, who deals with the subject in all its bearings in a true spirit of science, seeking not only to destroy error, but, wherever possible, to uphold truth as found in popular sayings. For this purpose he divides his arguments into: "(1) Lunar notions that are utterly absurd; and (2) those that are explicable by the aid of physical principles, and are therefore rational and useful in practice." I shall scarcely do more, in this short paper, than summarize these "notions," adding the cream of his remarks, and a few observations of my own. To merely enumerate all the popular sayings regarding the "moon," would require a volume to itself; but here we have to do only with moon-myths attributing lunar influence to the weather. Nearly all weather sayings are of the nature of predictions, otherwise of what use are they? Such as are to be found in "Herschel's Weather Tables."

J. W. Oliver says: "To the *first class* belongs the idea, in its various forms, of a direct lunar influence. The weather will be such and such, not because the moon's reflection of light is greater or smaller, not because her radiation of heat is more or less, nor because her position with respect to the earth is nearer or farther away, but simply because she 'changes' between certain arbitrary hours." Upon this Mr. Oliver remarks: "The lunar influence assumed here must be of an occult nature, as there is no pretence of physical agency (which Science demands) in the matter. The principle involved must be an astrological one, for in reality the moon is 'changing' every instant of time from new to full, and from full to new again, the 'quarters' being only stages in the process specially marked for the sake of convenience. But we are asked to believe that only these conventional 'changes' rule the weather." To this he adds: "Need the British public be assured that no such convenient orderliness in weather phenomena exists, and that the 'changes' of the moon are not confined to England, nor to any one country"—nor, I would add, to any one locality. The "changes" take place simultaneously all the world over. Who, may I ask, has not brain power enough to reason out the consequences of this great truth? Notwithstanding Mr. Oliver's anxiety to be fair and moderate, he cannot help using strong language occasionally, as when he says: "As an example of *elaborate nonsense* I know of nothing better than a table showing the probabilities of a change

of weather at, or after, each of the moon's stations throughout an entire revolution in her orbit, which received the honor of recognition and approval in an encyclopedia of not very ancient date." He then proceeds to demolish this "table" as he had demolished the so-called "Herschel's Tables." He says, "taking the ten specified points in each lunation, and calling a lunation roughly thirty days, and then averaging the probabilities, we discover that this table, which for all the world looks as if it might be the condensed result of years of observation and much laborious calculation, merely expresses (or conceals) the simple fact that, in every three days there are three chances to one that the weather will undergo a change!—which in England is only too true!

As to another popular saying: "If Christmas comes during a waxing moon we shall have a very good year; but if during a waning moon, a hard year." Here the agency is again not physical (scientific) but religious." He adds: "The moon is always either waxing or waning; it is her nature to do so. But that of itself signifies nothing: it is when *Christmas* (a religious festival) happens upon a waxing or waning period that certain conditions are to follow!" He next discusses the popular sayings regarding the moon's appearance in the sky: whether "lying on her back" or otherwise, and points out that in Scotland when the moon "lies sair on her back" it is a sure presage of bad weather (Jamieson), while in England the belief is exactly reversed. In this connection he indulges in a joke, and says, "the moon might lie sair on her back" were it she herself that was "bad," but scarcely on account of an approaching disturbance of the weather! This attitude, too, he says is a gradual one, like the "changes," and ought to exercise its influence through all the stages of its progress, instead of only when a weather-wise person happens to notice it! I may here add what he omits, namely, the conditions under which the crescent moon is tilted forward or backward. The sun itself (whose shine upon the moon causes us to see more or less of her face according to her position) is, of course, always on the ecliptic; but the moon sways to 5° on each side of the ecliptic. When, just after "new," she, too, is on the ecliptic, she necessarily must be setting straight over the same place as the sun, and be on her back, but when she is 5° south or north of the ecliptic, she necessarily receives the sun's light sideways, and is tilted accordingly. It would be easy to make a table of these attitudes, if any "use" could be found for them, and of course they would be useful "if" they had any connection with the "weather."

Mr. Oliver next proceeds to discuss one of the most wide-spread of all weather beliefs, the "Saturday moon." "The notion is that when the new moon falls on a Saturday it is invariably followed by a period of wet and unsettled weather. This even had the support of a Dr. Forster before the Royal Astronomical Society in 1848. But the Saturday moon is not sufficiently periodical. In 1881 not a single new moon fell on a Saturday. In 1883 there were three, in this year two conjunctions so distinguished. What sort of weather period can we imagine gnity of such eccentricities? So we are obliged to include this much respected saying in the category of idle superstitions." With this Mr. Oliver concludes the class of weather notions he distinguishes as "utterly absurd." With regards to class 2, or those sayings which have a real physical basis, we need not occupy much space, as they scarcely belong to the list in popular use. Whether the full moon emits "heat rays most of the dark sort" which tend to make full-moon nights less cloudy than other nights (over of course a whole hemisphere,

and not merely locally) is going beyond the object of this paper, viz., the moon's influence on local weather. More to the point (but still quite outside any "influence" exerted by the moon on the weather), is the belief that when the old moon is very visible in the new moon's arms had weather may be looked for. The visibility (at time of new moons) of that part of the moon's face unilluminated by the sun is caused by its being illuminated by the earth, i.e., by reflected sunshine from the earth. Vast masses of clouds to the west, hanging on the earth's surface, reflect more sunlight on to the moon than the earth's unclouded surface would do, hence the inference that to the west of us are huge rain clouds.

Finally, he throws a sop to those who will have some sort of theory left them. "A moon's quarter," he says, "is roughly equivalent to a week, and So-and-so once told me that he had very frequently noticed a tendency in the weather to change and repeat itself every seven days. A similar seven-day periodicity has been observed in the United States. The meteorological conditions of a large Continent, it must be remembered, are simpler than those of our little islands, and hence it is possible that a cycle almost completely masked here, might disclose itself there!" But he is careful to add: "It is not to be supposed that I am contending for a cycle due to the moon, only that there seems to be some evidence of the existence of a seven-day weather period which may sometimes happen to be coincident with the lunar phases." Well, on this I have to remark, that some sort of weather must be co-incident with the lunar phases; and as regards "a moon's quarter being roughly equivalent to a week," so is a week roughly equivalent to a moon's quarter; and in a very short time (for observations) they both get too much mixed,—any given phase of the moon being absolutely non-synchronous with any day, except once in nineteen years as discovered by Meton, hence called the "Metonic cycle." One more quotation from J. W. Oliver, and then we will leave him: "The moon exerts no influence upon our atmosphere strong enough, by comparison with the other influences at work, to produce a marked correspondence between the lunar and atmospheric phenomena. Of that we are certain. Let us therefore belabour the false doctrine upon which these notions are founded with all our might." (J. W. O.)

I will conclude with a few arguments which from time to time have suggested themselves to me. (1.) If the earth rolled in her orbit on an axis horizontal to the sun, we might possibly expect that some perceptible influence over the "weather" of a climate so monotonous would be exercised by the moon. But the earth's seasons, the polar ice, and the heat of the tropics are caused by the inclination of the earth's axis to the plane of her revolution round the sun, and the phenomena resulting from this are so varied and potent as to obliterate all traces of the moon's more feeble influence in any locality. (2.) In obedience to the sun's action upon oceans, and seas, and deserts, and mountain-ranges, and rivers, and swamps, tornados, cyclones and storms are constantly tearing here and there through our atmosphere, destroying all approach to equilibrium over immense surfaces, so that anything like regularity or constancy of mere weather conditions are rendered impossible; and no amount of reliable observations have been made to fix recurrences in the least degree. (3.) In spite of the moon's attraction, pulling in any directions she may, the tropical atmospheric currents change from north-east to south-west in obedience to the "sun's" north and south declination, and these changes—the most constant and recurring of any—are more or less

accompanied by storms and rain, and cloud, as hot deserts, ocean-currents, the polar snows, the surface of the ocean itself, and the highest mountain-ranges &c., have been exposed to,—or hidden by cloud-banks from the sun's action upon them. And as these occur over all the earth's surface, all parts are constantly subject to different degrees of exposure, resulting in chaos as regards "weather" in any particular place. (4.) The "seasons" are necessarily constant, as such, from the great regularity of the sun's annual journey south to north and back; but "the inconstant moon, that monthly (daily, hourly, every minute) changes in her circled orb," would produce just as inconstant weather. It is the revolution of the earth on its axis that causes the constancy of the diurnal tides, which otherwise, would be lunar—monthly. As it is, the moon has no influence over the "weather" of the ocean, but only over her mean level. (5.) Yet, if the infinitesimal extent to which the moon does affect the atmosphere, as a whole hemisphere, (and not any minute portion over any particular locality) could be measured, it would be found, doubtless, to be greater than her influence over the weather of the ocean, that is, its currents, temperature, calms and storms. This fact should not be forgotten when it is claimed that the moon's influence over the height of the waters of our globe is analogous to the influence, it is assumed, she ought to exercise over the mere "weather" of our atmosphere. There is no analogy over the level of water of one element, and the meteorological conditions of another element in ten thousand times ten thousand different places. (6.) In a scientific paper just to hand I find the following paragraph, which, as showing how differently the "moon" behaves in different places, I copy and close with:—"As an instance of the comparative uselessness of generalisations from records of rainfall, it may be noted that, according to an observer at Caversham, Oxfordshire, the rainfall there, during April amounted to 70 in., while in April 1890 it was recorded at 1.87. At Shifnal, Staffordshire, the amounts were reversed, for 1.96 fell during last April, while the rainfall of April 1890 was recorded as only .83. The records bear out what is well known to all close observers that rainfall varies considerably within comparatively small areas." (*English Mechanic*.) So that a moon gazer must unlearn his old lore and study now whenever he changes his habitat. And then, if he is wise, he will no longer consult the moon, but the local conditions that surround him.

[After all is said, some may have lingering doubts whether the moon may not have some influence on local conditions. The sunspot cycle theory is met by the same objection of varying weather in different parts of the earth, and yet a good many scientists, including Blanford, believe to some extent in sunspot weather cycles.—Ed. T. A.]

A NEW WORK ON CACAO; PROPOSED ANALYSES OF CEYLON TEA BY MR. HUGHES; RAG MANURE FOR TEA.

LONDON, Aug. 14th

It may serve a useful purpose just to draw the attention of your planters to the fact that a new work on cacao, by Mr. J. H. Hart, of the Botanical Gardens, Trinidad, is now in the press and will shortly be issued. Mr. Hart undertook the work with the sanction and full approval of the Governor of the cacao island; and there is every reason to believe that his experience will have enabled him to lay some very

novel and useful information before the cacao planters of Ceylon.

Some months back my letters told you of a negotiation which had been going on between Mr. John Hughes, the well-known agricultural chemist, and your Planters' Association, as to his undertaking certain analyses of tea with the view of determining fully the characteristics of such kinds as might appear to be most in demand in the home markets. Somehow or other no determination seems to have followed on this negotiation, and nothing further had been heard as to it until the matter was brought—as I believe, by Mr. Borron, to the notice of the tea committee of the London-Ceylon Association. Influenced by the representations made to it, that committee passed a resolution stating its opinion that such an analysis as had been suggested by Mr. Hughes should be carried out, though I believe the recommendation was accompanied by a rather narrow limitation of the amount to be expended upon it of £15. Hearing of this action of the committee, I sought an interview with Mr. Hughes during the present week to learn if he could communicate to me anything further beyond what I was enabled to write you when the question was first mooted. Certainly one thing that Mr. Hughes remarked to me on this subject was a novelty to me, as we suspect it will be to a good many of your readers in the colony. Mr. Hughes told me that he had come to the conclusion, from his experience with the tea-tasting fraternity in London and elsewhere, that it was the presence of a greater or lesser degree of tannin in the tea that determined the valuation put upon it. These experts looked in a very large degree to strength as governing the prices which can now be obtained for teas, and they state that it is the proportion of tannin which determines this strength and therefore the market value. No doubt this view applies more fully only to those teas which we drink by the classes to whom economy is a necessity, but there is no doubt that these form the bulk of tea consumers and that it is their taste or requirements which have mainly to be considered. Anyway, if Mr. Hughes has rightly concluded, it appears to be a fact that the more tannin there is in your teas the better prices they fetch, and of course, as this must govern the action of your planters, they will doubtless try and produce teas in which a high proportion of tannin is to be found. Now according to all my experiences, it has always been recommended to us tea drinkers at home to purchase such teas as are possessed of the least amount of tannin, and delicate flavored teas at high prices have been sought for. If what Mr. Hughes tells me prove to be correct, we are therefore on the eve of a revolution as to the highest qualifications of tea, so far as the price it may fetch is concerned.

During my conversation with Mr. Hughes the topic of the rag manure sent out by him for the Mariawatto estate come up once again. He told me with reference to this that he had heard nothing further as to the results obtained with this new fertilizer on the estate mentioned; but he remarked that he felt the most entire confidence that sooner or later its beneficial effect must become evident. "Indeed," he said, "having seen the effect of its application myself to the olive bushes both in France and Italy, I do not for an instant doubt that similar good results must follow its application to the tea bush. There is only one point on which there is any doubt in my mind, and that is that no opportunity was given me for testing a sample after the consignment had been put on board ship. It was most

desirable that this should have been done, because, of course, it is impossible for me to say whether the manure sent out really contained all the constituents on which I relied when recommending it. It is only within the last few days that I saw a shipment of manures just starting for Ceylon, and it is evident, therefore, that the planters there are commencing to use fertilizers prepared at home. You cannot too strongly urge on your friends in the colony the desirability of learning, before their orders leave England, that they have been executed in exact accordance with their instructions or the advice of any expert they may have consulted. If this be attended to, manures sent out from home ought to be just as reliable as to their results as is the application here of farmyard manure. We know that the last must produce certain results. We do not think twice about it, and indeed, if failure as to this does occur, we may be quite certain that it has either been badly applied or that there has not been the rainfall sufficient to soak the ground with its constituents. For a similar reason, therefore, I say that the manure sent out for Mariawatto must if it was manufactured in accordance with the specification of its constituents yield sooner or later all that had been anticipated of it by me."—London *Cor.*

NOTES ON PRODUCE AND FINANCE.

THE "LANCET" ON TEA DRINKING.—The *Lancet* although never weary in suggesting new sources of danger to the community, finds it necessary occasionally, to fall back on an old one: It varies the monotony of the situation by dividing its favours between alcohol and tea. In commenting upon the examination at the Waltham Abbey Petty Sessions of a woman who is charged with the wilful murder of her two children, it says "that a statement of some importance was made by the divisional surgeon of police, Dr. G. Fulcher, with reference to the habits of the prisoner. On being interrogated with regard to tea-drinking, she said she had been in the habit of taking a large quantity, that she had given it up, but had recently resumed the habit in consequence of her troubles. Dr. Fulcher was of opinion that the prisoner was the subject of melancholia, and he expressed the belief that the taking of tea in excess tended to undermine the constitution. The powerful effect of alcohol in excess as a nerve poison is a matter of daily experience. That many of the ailments from which women suffer are at least aggravated if not excited by excessive indulgence in tea—not as an infusion, as it ought to be, but as a decoction—is equally well-known; and although we are not prepared to admit that this habit would actually induce a condition of melancholia, there is little doubt that in a woman of neurotic temperament, especially if her food were defecient in quantity and of poor quality, the use of this beverage in excess would be one of the factors in producing and perpetuating a condition of mental instability. It would be well if those to whom the frequent cup of tea from the pot—which has a permanent place at so many firesides, and has become almost a necessity, as they think—recognised fully the pernicious effects of this over-indulgence, effects which are only surpassed in importance by those of the occasional 'drop of gin,' of which so much is heard in the out-patient departments of our hospitals." The evils of stewed tea taken in large quantities have been pointed out again and again in the *Lancet* and other medical papers. It is not the tea that is at fault, it is the ignorance of the people who prepare it. If people will persist in making soup of tea instead of infusing the leaves, the blame is not attributable either to the tea or to those who grow it.

THE IMPORT OF TEA AND WHEAT.—According to the Board of Trade Returns for July, the quantity of tea received from China is nearly £3,000,000 greater than in the corresponding month of last year, but the consumption here of that kind of tea again shows a decline, Ceylon tea being more and more in demand. As to wheat, Russia sent only 673,303 cwt. against 2,406,055 cwt. In July 1890, but British India sent nearly as much again last year, the quantities being 1,555,556 cwt. and 888,975 cwt. respectively.

TEA IN BURMAH.—Tea planting operations in Burmah do not thrive so well as they should. There were five tea plantations in the Province at the end of last year; but the area under the tea plant was only seventy-eight acres against 172 acres in 1889, the falling off being attributed to the want of sufficient labor for one or two of the plantations. The out-turn of manufactured tea also dropped from 12,250 lb. in 1889 to 5,710 lb. in 1890.

FOOCHOW NOTES.—Teamen are not, we understand, grumbling at the result of their ventures this year, indeed they are well satisfied with the out-turn of common teas and second crops, but it makes them wince to find that their profits are simply carried to their credit in account to meet the heavy losses of the past two years, instead of having them to put into their pockets.—*Daily Echo*, Aug. 1.

PLANTING IN NORTH BORNEO.—The *Singapore Free Press* of 13th Aug. in an article on North Borneo says:—

A favourable feature is the way in which the Chinese coolies are taking up land for themselves, and settling down permanently on North Borneo soil. One particularly interesting instance is that of a party of Iakkas, a tribe of Chinese who are, as a rule, really good agriculturists, now engaged in the cultivation of Liberian coffee on their own account. They took up some land in 1883 and planted coffee, cultivating also vegetables, ground nuts and other produce, which they were able to dispose of readily and thus keep themselves going. That little community, nearly all Wesleyan converts, it may be stated, have year by year added to the area of land under coffee, until they have now no less than one hundred and seventy acres bearing Liberian coffee, and, it is reported on good authority, will by the end of 1892 have actually four hundred acres devoted to growing coffee. This single instance, a very promising one, indicates that the Chinese are readily and spontaneously taking to settlement and cultivation in North Borneo. It also shows that, independent of the bad luck or the mal-administration of European ventures, coffee may before long become an important article of export from North Borneo. That these Chinese labourers, without capital, and living from hand to mouth, should devote themselves to an agricultural experiment in coffee on so large a scale ought to be taken as an encouraging sign by planters proceeding to Borneo who have capital to back their enterprise and carry them through all the initial difficulties. Coffee prices are very encouraging just now, and the production in several important fields has fallen away, so that the future of coffee cultivation in this part of the world seems to be full of promise. In Ceylon there is little or no suitable virgin soil in the hands of the Government, and Ceylon investors who are turning their minds to coffee are beginning to look abroad for some promising region where they may utilize their capital in planting. It is to the Straits and Borneo that attention is now being turned. The ten agricultural land grants, which the Perak Government offered on specially liberal terms, have all been applied for, chiefly by Ceylon men, we hear. And North Borneo is also apparently about to profit by this increased attention given to the opening up of new areas to coffee cultivation, for we are informed that there are prospects of the early investment of capital, from Ceylon and elsewhere, in the raising of Liberian coffee there on a considerable scale. If North Borneo has, through circumstances avoidable and otherwise, not attained any distinct success yet in tobacco, it may find its reputation, as a field for enterprise, vindicated before long in the direction of coffee.

INFERIOR CEYLON TEA.—The *Madras Mail* of 18th August has the following:—

The following passage is from a London tea-agent's letter:—"Some mess from Ceylon, which they call tea, has been sold at 1d and 2 1/4 per pound, and we are to have, they say, continuous supplies." Whereupon a contemporary remarks:—"Ceylon is about to kill tea as it has killed coffee. Not having a particularly fine soil, but an exhausting climate, the growers give the plant no rest, with the result that the value of their tea is falling yearly, and, unfortunately, in forcing down prices it brings down with it for the time being all other classes of tea."

The contemporary referred to is we believe the *Englishman*. The *Madras Times* in quoting the extract says:—

This policy of flooding the markets with worthless leaf is most shortsighted, and we wonder that the Ceylon Planters' Association do not at once take the question up.

We think that there can be no doubt that a good deal of very inferior tea has been sent home lately from Ceylon, as proved by the brokers' reports and low prices; but that the pessimistic forebodings of the Calcutta paper (representing the Bengal tea planters) are likely to come true we certainly do not believe. However, our tea planters should be careful not to give their enemies an excuse for ill-natured remarks.

THE MAGAZINE

OF

THE SCHOOL OF AGRICULTURE,

COLOMBO.

Added as Supplement monthly to the "TROPICAL AGRICULTURIST."

The following pages include the contents of the *Magazine of the School of Agriculture* for September:—

PLANTS AND WATER.

PLANTS may, in a general way, be said to be composed of water and solid material. The amount of water in plants is very variable—ripe seed containing about 13 per cent; stems and leaves of ordinary herbaceous plants, on an average, 70 per cent; many water plants as well as some fruits and roots, 90 per cent; fungi up to 95 per cent.

According to Nageli's theory every molecule or ultimate solid particle of the plant is surrounded by a film or sheath of water; when the molecules are large, the proportion of water is small, while when the molecules are small, the proportion of water is large. The quantity of water, according to this theory, varies only within certain limits. If it be present beyond these limits, *i.e.*, if there be too much or too little water, the texture of the plant will be destroyed. Loss of water causes a contraction, gain or absorption of water an increase or swelling of the plant body. The proportion of water in a plant depends partly on the season of the year; and when growth is going on vigorously there is always an increase of water.

Nearly all the water in plants is taken in by the roots, though, according to Warrington, when rain occurs after severe drought, water may be taken up to some extent through the leaves.

Apart from the necessity for water in the plant to meet the evaporation which goes on through the leaves, and thus prevent what is popularly spoken of as the drooping of the plant, water is

very necessary as a medium by which plant food in the soil enters the plant. All the plant food which is derived from the soil is taken in as solutions by the process of osmose. It is a common fallacy that plant food is also taken into the plant as solid matter. The solutions which are taken in by the roots are either of substances found ready dissolved, or of substances which have been dissolved through the action of the acid sap in the roots. A tolerably large amount of water is required to dissolve and carry a small amount of plant food from the soil into the plant, as the solutions which enter are very weak ones. Owing to the rapid evaporation of water through the leaves, these weak solutions are concentrated in the upper parts of the plant, and the required ingredients are appropriated by the plant for the formation of new tissue, while those not required are got rid of as incrustations on the older tissues.

A little time ago we heard artesian wells objected to on the ground that the water they supplied was practically pure water, that is water without silt (so it was put to us); it being maintained that the water of artesian wells was perfectly useless for cultivation purposes. Now water available by a plant may have silt in suspension, plant food in solution, or neither, but only certain substances which help water to act upon insoluble plant food in the soil and render it soluble. While irrigation water (as irrigation is carried out in Ceylon) carries silt in suspension, it is not to be supposed that it is of value solely as a carrier of silt, for besides carrying substances in mechanical suspension, it would also hold substances in solution, as well as act as the medium for conveying soluble plant food however derived, into the plant. To say that the supplying of water, without plant food in suspension or solution, to a plant is of no value to it, is to deprecate all "dry cultivation," to say that rain is a superfluity in agriculture, that watering by the hand in Horticulture is a waste of labour.

Let it however be remembered that water in addition to being a carrier of silt may contain up

to 50 per cent of dissolved matter in solution, and is of the greatest importance in the plant economy as a medium through which plant food is taken up from the soil as solutions into the plant (a function which even chemically pure water—which is never found in nature—may perform), while it is also necessary to meet the evaporation that goes on through the leaves, and the full value of water will be better understood.

OCCASIONAL NOTES.

We are glad to be able to mention that the Circular regarding the project of issuing Sinhalese leaflets on practical agricultural matters, has elicited replies of an encouraging nature, not only from Government officials but also from private agriculturists. Among the latter are Mr. Gunaratne, Athapattu Mudaliyar of Galle, who has before now showed the active interest he takes in the welfare of his countrymen, and Mr. H. D. Gunasekera, whose promise of support is very encouraging.

While Mr. Gunasekera sets a good example to our old boys by promising to take a large number of leaflets to be distributed among the villagers about his own home, Mr. J. A. G. Rodrigo, the energetic Agricultural Instructor at Bandaragama, who orders 350 copies, and hopes to take in 150 more, sets an admirable example to his brother Instructors. Among others who have promised to support the Sinhalese leaflet project is Mr. Jayasuriya, the Mudaliyar of Rayigam Korale.

We have much pleasure in notifying that the Government have sanctioned the purchase of a stud bull for the School of Agriculture. It is expected that the animal, which is one of the Saidapet farm stock, will be brought over from Madras very shortly. It has been also decreed that a block of land, 43 acres in extent, adjoining the School of Agriculture shall be handed over to that institution. The action of the Government in these two instances leads us to infer that the welfare of native agriculturists, in whose interests the School of Agriculture was founded, will not be lost sight of during H. E. Sir Arthur Havelock's reign, and to expect that the few liberal measures which have been reserved for an energetic Governor to pass in favour of Agriculture will be *fait accompli* before the end of that reign.

There seems a fair prospect of a good trade in dried bananas being opened out with England and Germany. An endeavour is being made by the Guild of Co-operators of Queensland to deal directly with the great Co-operative Undersale Stores in England. It is expected that the bananas, which are merely dried on wire-netting, besides being used like dried figs as dessert, will be stewed like prunes, cut to the size of raisins and used in puddings. Once the export of the dried fruit is established, there will be another opening for native cultivators, who, if they cannot be expected to dry their own fruit, might send in their supplies of fresh fruit to some enterprising man who owns a fruit-drying apparatus. We have not yet heard the opinion of the English grocers on the

specimens of jams and jellies made of Ceylon fruit, which Mr. Baumgartner is said to have taken with him to England.

According to Australian experiments, one pound of dried bananas soaked in water and stewed for half an hour has been found to swell up to 5 lb in weight, besides a sweet syrup being produced without the addition of any sugar. A shipment of dried fruit sold in London at 6d. per lb. and if the nett profit shows 3d. a pound, the industry should pay very well. It is even thought that a company on a large scale could make bananas pay well at 2d. per lb.

The "passion fruit" is the product of the common passion vine, *Passiflora edulis*. The *Agricultural Gazette* of New South Wales for May gives notes regarding the cultivation of the vine, and distinguishes three other species which are recommended for cultivation. The first is *Passiflora macrocarpa*, the large granadilla; second, the *P. maliformis*, or sweet calabash; and third, the *P. quadrangularis*, the common granadilla. The soil best suited to the growth of the passion-vine is said to be one of a rather loamy nature, and that is fairly rich in humus, though the vine is so hardy that it will grow in almost any soil and situation. Fences for trailing the vine should run as due north and south as possible, so that the vines may receive sunshine on both sides of the fence. The vine can be propagated by cuttings, layers and seeds. The latter produces the most vigorous plants, and the seeds should be collected from the earliest ripened fruits.

Prof. Church's analysis of the ground-nut (*Arachis hypogaea*) shows that it contains of water 7.5, albuminoids 24.5, starch 11.7, oil 50.0, fibre 4.5, ash 1.8. The oil which forms so large a proportion of the ground-nut is of a clear, pale, straw colour; it will not become rancid and improves with age. It is known in commerce as "nut oil," and is not only adulterated with, but is substituted for olive oil. It is valuable as a lubricant for delicate machinery. The residue or cake after extraction of the oil is a very fattening cattle food, as well as a valuable fertilizer. "Chocolate cakes" are said to be manufactured to a large extent out of ground-nuts alone in the United States. The stems of the plant, after removal of the crop, form a most useful fodder which cattle are very fond of.

Mr. T. B. Kehelpanala writes:—"Gampola-wela, as the name indicates, is a row of fields situated in the vicinity of the town of Gampola. These fields have an historical reputation. One of the late Kandyan Kings dedicated the fields to the Dalada Maligawa (the tooth relic palace at Kandy) with a view to gaining merit, and they are still held in undisturbed possession by the temple. The fields in the Kandyan Provinces are generally irrigated by *amunams* or streams. The *amunam* which flows to Gampola-wela takes its rise from Dolosbage—a distance of about 8 miles. It is said that in former times the breadth and the depth of the *amunam* in question was so great, that the king used to row about in it, hence it was afterwards known as *Raja Ela* or

the *King's Stream*. This stream is now considerably reduced in breadth owing to, I suppose, the deposit of sediment. The fields are about 250 anjams in paddy sowing extent; and a panoramic view of them could be got from the *Mariawalle Tea Factory*. An *atura* or granary with carved colossal pillars for the storing of paddy was constructed by one of the later kings. The wooden part of the structure is massive and grotesque, and yet ornamental. This *atura* was capable of holding about 20,000 bushels. The late Murtyu Mohandiram of Ganpoh, a Kandyan Chief reputed for his riches, repaired the structure, taking care to preserve its former shape and style. This *atura* is at present known as the *Gampola Atura*, and belongs to Kehelpanada Pohath Walariwa. The fertility of these fields has been reduced to an appreciable degree, as may be proved from a comparison of present crops with the produce of former times. The fields being Maligawa property are exempted from all taxes."

A correspondent writes:—"One cannot but admire the excellent arrangements made by the Agricultural Department of Madras for gathering information regarding the condition of all branches of agriculture. Men qualified for the work of inspecting and reporting on such subjects as crops, cultivation, cattle, &c., are sent about the country to enquire into these matters, with a view to rendering such timely aid as it is possible to give, when assistance is needed. Here in Ceylon it is only after the lapse of much time (and it is during such time that any action, if necessary, should be taken) that the existence of any abnormal circumstances connected with any branch of agriculture is made known by a casual reference to the fact in the report of a revenue officer. As might be expected the reference itself is too vague to be of any practical value, no details, reliable facts and correct figures being given. While in the Madras Presidency information is gathered firsthand by Agricultural Inspectors who travel about with this object in view, in Ceylon similar information is commonly gathered by some illiterate unpaid minor headman, who so far from possessing a special knowledge of agricultural matters, is sometimes poorer in his general attainments than an ordinary village schoolboy. The information gathered by these minor headmen is passed over to others, who though higher in station are not more intelligent than they; in due course the information reaches the Mudaliyar, through whom it reaches headquarters. I am able to give an instance of how 'reports' are made from my own personal experience. A village headman casually enquired of me what weight of arrowroot tubers would be sufficient to produce one pound of flour. Having had no experience of the preparation of arrowroot flour at the time, I answered that I was not in a position to give a definite answer, but that I thought about 10 or 12 lb. would be necessary. Some time afterwards it came to my knowledge that the headman who questioned me had to furnish a report on arrowroot, and had mentioned in his report that 12 lb. of tubers were necessary to produce one pound of flour. Fortunately the headman not wishing to let it be known that he had got this information secondhand, did not mention the name of his

authority. This report passed through several hands, appearing no doubt as the outcome of the personal experience of the individual who last submitted it. In the end the figures of the Wewita Agricultural Instructor, which were obtained as the result of numerous experiments, and which were published for general information, were called in question on the authority of the report, whose history I have narrated!" [We cannot but think, as we earnestly hope, that this is only an exceptional case.—Ed.]

KAPOK OR THE SILK COTTON TREE.

(*Eriodendron Anfractuosum*.)

By W. A. DE SILVA.

There are several species of plants which supply a silky down, known by the popular name of Silk Cotton. In different countries this name is applied to the product of different species of plants; but most of these products have had hardly any commercial value, as silk cotton is totally unfit for spinning purposes. The staple obtained from some of the species has now got a certain economic value, as it is used as stuffing material for pillows and cushions, and sometimes for adulterating with genuine cotton and wool. There are two species of trees in Ceylon which produce the silk cotton—commercially known as Kapok. Among these the most important one is the *Eriodendron anfractuosum*, the Sinhalese Imbul, and the Tamil Elavum. This tree thrives well in the warmer parts of the Island.

It generally grows wild, but is at present cultivated to some extent in certain localities. It must not, however, be understood by this that the tree producing the Kapok is ever systematically cultivated, but it is only planted here and there in plantations.

The tree attains to very large dimensions, often growing to the height of eighty feet. The trunk is straight and the branches are borne on the top of the tree. The bark in the lower part of the mature trunk is covered sparsely with thick prickles, which form into small knobs as the tree grows older. The timber of this tree is very light, and hence is only adapted for the purposes of fuel, but of late, after being sawn into planks, it has been used in the manufacture of tea boxes, &c.

The plant begins to bear in its third year. The flowers which are of a pretty large size with a thick whitish corolla and a cup-shaped green calyx are borne once a year in February-March, and the fruits which are formed very soon after are ready for plucking in April, May and June. During the flowering time flying foxes frequent the trees, as they are very fond of the young blossoms. The fruits are long and cylindrical, about five inches in length and three in circumference, and are filled with a downy cotton—staple very short and curled—interspersed with black seeds. This down forms the 'Kapok' of commerce. The productive power of the trees differ much according to size and age. For instance, a fully-grown tree with numerous branches might yield about half a hundred-weight or even more of Kapok, while a young tree with a few branches might yield not more than a pound or two.

The export trade in Kapok in Ceylon is of very recent origin, probably not older than ten years. Previous to this the product had only a local demand for the purposes of stuffing pillows, cushions, &c., and this demand was so small, that it did not even encourage the collection of the Kapok found on the trees which were growing wild.

Since an export trade began, the demand has increased so much, that not only is Kapok carefully collected from the trees growing wild, but great care is taken to preserve it and plant new trees wherever the opportunity occurs.

There is a large demand for the article in Australia, where it is used in the manufacture of pillows and cushions, and it is also exported to Holland and Fiji, where it is said to be used for mixing with cotton and wool in the manufacture of cloth.

Ceylon is not the only country where this article is produced, for Java, Sumatra and the adjacent Island are also exporting it largely.

The cultivation of the Kapok-producing tree in Ceylon could be very much extended, not by growing it as a separate product, for then it would not pay, but by planting the trees at intervals in the lowcountry plantations as shade and boundary trees.

The other species of silk cotton found in Ceylon is the *Bombax Malabaricum*, the Katu Inbul of the Sinhalese. It is not so commonly met with, and may be said to be never cultivated. The plant is characterized by the sharp prickles which are found abundantly on the stem. Its leaves are smaller and greener than those of the Eriodendron, and the flowers bear scarlet corollas. The fruits are smaller in size, but contain silky down of rather a slightly better quality.

Among the other less known varieties of silk cotton, which are not utilized commercially, the giant bombax of South America may be given as an example. This plant is known as *Bombax ceciba*, and is found of very large dimensions. Waterton in his "Travels in South America" gives a graphic description of the tree, and says that the staple is very short and is of a yellowish colour, and that no use has been found for it, except for packing the arrows of the South American Indians and stuffing pillows.

THE CULTIVATION OF THE COCONUT PALM. No. 1.

The cultivation and nurture of the Coconut Palm (*Cocos nucifera*) has been for many years past the subject of much speculation, and especially during the last half century, in the first part of which Europeans in Ceylon first opened out large estates of this valuable tree, notably in the Eastern Province, and more particularly in the District of Batticaloa. Before this time of course many large plantations and village plots were cultivated by the natives of the country, but no scientific method of planting and manuring was before this attempted, nor was the making of 'Copra,' with care and attention to details, the speciality that it is at the present time.

Of the native method of cultivation I will say but little—only one system being universally followed. The ripe nut is placed upright in the ground, the 'eye' or sprouting end appearing

about one to two inches above the surface. This is carelessly and irregularly watered, and the plant, transplanted in due time, is ill-attended to during its tender years, and then left to its own devices till the fruit, when matured, is picked for use or sale, or is plucked immature for the purpose of drinking the coconut water.

On the first planted estates the European proprietors following the native custom as far as the *planting* of the nut in nurseries was concerned—made no selection of nuts, and planted them vertically, that is, as they hang on the tree. The main difference however between the European and native methods consisted in a careful watering, and in the regular manuring of the plant from time to time. A few proprietors imported nuts for planting from the Galle and Matara or the southern sea border—the habitat of some of the finest trees in the Island, but strange to say, many of the estates so planted, suffered in comparison with those planted with local seed—the nuts becoming smaller and smaller every year, the trees failing in power of production, and finally dwindling away, till within the last few years whole acres—indeed large portions of estates—have died out, and many estates abandoned in consequence.

Of very late years a new method of planting the nut in nurseries has been followed, the results being up to date eminently satisfactory.

The methods followed by Dame Nature in the propagation of seeds—of whatever kind they may be—are infallible, and he who departs from the rules she lays down, travels out of the circle or sphere of success; and when we see whole continents and islands clothed with great forests where the trees have been self-propagated, must accept the axiom that Nature is right, and that they only wrong who depart from her unchanging rules.

In the case of coconuts it will be found by the most careless observer that the nut, in falling from the tree, always lies on the ground horizontally or on its side, in which position it is best fitted for sprouting, growing, and successfully arriving at maturity, as I shall now proceed to demonstrate.

The young or tender nut is found to be full of a liquid or coconut water as it is called—so excellent a drink—which not only keeps the nut moist but helps to bring to perfection that portion of the nut which hardens by degrees till it reaches the useful or 'Copra' stage, and holds not only a rich milk but a valuable oil in its tissues. This coconut water is absorbed by degrees by the maturing nut which will be found to contain a less amount, probably only a half, the original quantity.

The coconut being rather of an elongated shape the sprouting portion lies at one end, so that if planted in a vertical or upright position, the water only filling half its cavity and the sprouting eye being at the top,—the eye remains dry and unmoistened, and though the seed sprouts from the dampness of the soil, the sprout does not attain the full vigour that it would do under other conditions.

But if the nut is planted horizontally,—or in the natural position it lies on the ground as it falls from the tree,—the sprout or eye never dries, and it receives constant nourishment from the water within which keeps it moist even though the cavity of the nut be half filled.

In the same way a bottle of wine half filled and corked, and laid on its side will always have the cork moist. I think it may be safely assumed that a nut planted in its natural or horizontal position, will in course of time germinate more successfully and produce a better and more vigorous plant than one which is planted vertically or in an unnatural position.

So much for the position of the coconut when planted in the ground.

It will be found that the selection of large vigorous nuts for the formation of a nursery requires great consideration. The nut should be well matured, but not too much withered or shrivelled up.

Nuts which have remained long in store should not be selected, and the best should be chosen from large quantities freshly picked. If possible those nuts should be taken to gradually form a nursery, which have fallen of themselves and have not been picked. On an estate of 300 or 350 acres, from 2 to 300 nuts will drop from the trees in 24 hours, or in one day and one night, and 250 nuts will be quite sufficient to plant out one large nursery bed, and this process may be repeated till 10,000 nuts have been laid down.

The nurseries should be well watered, about twice or three times a week. The soil should be kept moist but not flooded or drenched with water, particularly when the sprouts begin to appear, as water lodges in the eye which is somewhat hollow and sometimes rots the young sprout. It is well to keep the nursery clean, as dirt attracts worms and beetles, which not only attack the sprout, but the tissues of the nut as well.

R. ATHERTON.

(To be continued.)

NOTES FROM A TRAVELLER'S DIARY.

I had lately the pleasure of visiting the Happy Valley Industrial and Reformatory Schools. It is too soon yet I think to judge how far such Institutions as this will be a success and benefit to the Island. They certainly deserve to succeed, for the work of reforming juvenile offenders is in itself a most noble and bold undertaking. A great many of the boys who are taught here are, I believe, orphans, and they are therefore at the sole disposal of the Wesleyan Mission, under whose auspices the Institution is conducted.

Opinions differ as to what are the best industries that should be taught in our Industrial Schools. Some people think that local industries should be taken up and encouraged, while others think that foreign industries should be introduced and adapted to local circumstances. This question will no doubt be soon settled, as the Colombo Technical School, which is likely to be opened at no distant date, is expected to teach just those industries which our boys should learn.

Carpentry, Shoeing, Printing, Blacksmith's work, and Agriculture are some of the industries at

present taught at Happy Valley. Everybody will agree that a knowledge of agriculture in all its branches will be of much practical benefit to the youth of Ceylon. Sheep-rearing, dairy-farming, and horticulture are some of the branches of agriculture to which attention is paid at Haputale, while experiments have been made in viticulture, cotton, tobacco, paddy cultivation, &c. Cotton, I am afraid, is not likely to be of any success in this part of the Island. Speaking of cotton, I must repeat here my advice that it should be grown together with some other crops. There are many practical planters who agree with me in this view. The so-called success of cotton has been the case in only one out of a dozen experiments. Whether the failures recorded are due to bad seed, bad cultivation, or climate, has yet to be ascertained. Until then it will always be safe to grow cotton with some other crops.

The Agricultural Instructor attached to the Happy Valley Industrial School is, I believe, paid by Government. The question is where will the boys of the Institution go when they become men, and what will they do? As I have said before, a great many of them, if I am not mistaken, are at the sole disposal of the Wesleyan Mission, and the authorities of this institution will therefore, I believe, see that the young men are placed in good situations. We may reasonably expect that some of them will be sent out to colonize, and when this has been accomplished, and when the lands which have been lying idle for hundreds of years under some of the best tanks in the Island are brought under cultivation by trained boys from Happy Valley, we could then say that this institution has been of real benefit to the Island.

RICE CULTIVATION.

The Madras Agricultural Department has published the more interesting and useful parts of a monograph on rice cultivation in Italy, where, though the traveller never expects to see fields of waving paddy, a good deal of attention seems to be given to the growth of the crop.

Rice is supposed to have come out of Orissa, and hence its name *Oryza Sativa*. The earliest mention of rice is found in the tragedies of Sophocles, and it is supposed to have been first introduced into Europe by the Greeks of Alexandria. The Museum of Agriculture at Rome is said to contain 347 varieties of rice collected from all parts of the world.

There is a good deal in this Italian monograph said in praise of deep ploughing, and among its advantages are mentioned increase in feeding area, destruction of weeds, increase in retentive power for water, and minimising of danger from drought. It is further stated that deep ploughing increases the outturn by about 9 bushels of paddy per acre, that is of course where the substratum is not of a sterile nature.

The section on soils and manures contains much useful matter. Rice is said to require soils rich in potash and nitrogen, not wanting in phosphoric acid and not rich in lime. It is stated, however, that different varieties affect some rich and some comparatively poor soils. As

to depth, the plant has superficial roots and can adapt itself to a very thin stratum of fertile soil, but, if it can send its roots deeper, it will, like all cereals, give a better crop. Generally the best soil is clayey with a moderate dose of lime, and a little silica and humus; afterwards follow clayey calcareous, then calcareous, and lastly silicious, but few soils are absolutely unsuited. An interesting table of analysis gives the composition of paddy, rice, &c., taken from an acre.

The composition of the 287 cwt. of paddy got from the acre was found to be 21.3 lb. of nitrogen, 133.5 of ash, 14.1 of phosphoric acid, 10 of potash and 5.3 of lime. The composition of the rice (11 cwt.) was 13.5 of nitrogen, 17.4 of ash, 5.7 of phosphoric acid, 3.6 of potash, 1.2 of lime.

With regard to manures we read: It is usual not to give any manure on good soil and in succession to meadow for 2 years and for 1 year on average soil or in succession to cereals. In any case, some manure is spread the third year. This however would not answer on perennial rice-fields when there is no rotation. In these, yearly manuring is essential to maintain the quality of the produce constant, and here it is particularly advisable to use alternately manures of different kinds such that one shall correct the defects of another. The manures used in Italy are lupin seeds, roots of monks' grass or *Rumen patenticia*, meadow turf when ploughed in, stable manure, stable drainage, waste of hemp, flax, &c., ashes of various plants, also bones treated with sulphuric acid or calcined. This last is of great value, and the same is said of normal and phosphatic guanos. Green crops are also ploughed in, for which those most used are red clovers, rye, vetches, oats, &c.

The practice of alternating rice with other crops dates from the time of the introduction of rice into Italy, but it has become much more common of late years, since it has been found to increase the outturn. The principal crops with which rice is grown in rotation in Italy are oats, wheat, grasses, maize, flax, clover and various fodder plants.

With regard to the question of irrigation we are told that it is impossible to establish any universal rules as to the quantity of water required as it depends upon too many causes, such as porosity of soil, quality of rice-field, that is whether permanent or in rotation. According to the engineer Cantalupi, in Lombardy 1.23 cub. feet per second suffices for about 64 acres of not very porous land; this is equivalent to 1 c. ft. per second to 54 acres or .02 c. ft. per second per acre. In Verona and Montovn .085 and .048 c. ft. per second are considered sufficient. Berti-Pichat put down the quantity required per second per acre generally at .043 c. feet, while Cantoni and De Regis fixed the average quantity at .02 c. feet per second per acre for rice in rotation, and .016 for permanent fields. Paolo Angiolini, another engineer, gives .036 c. feet for stiff soil, .071 for less stiff soil, and .14 for very porous land. The Societa d'Irrigazione Vercellese, a large association of proprietors who irrigate their own lands with Government water consumes on an average over several thousand acres, .038 c. ft. per sec. per acre. On their clayey lands they use barely .019.

The sources of supply of irrigation water in Italy are:—Canals, in 63 per cent of the total area, rivers and streams, in 24 per cent, springs, in 10

per cent, artificial reservoirs in 2 per cent, and lakes and ponds 1 per cent.

The water from canals has to be paid for.

The paddy crop in Italy is said to vary from 22 bushels to 100 bushels per acre, or an average of about 61 bushels for rotation rice-fields and 53 bushels per acre for permanent rice-fields.

The above résumé we think should not only prove interesting, as it would from merely comparing the system of cultivation in Italy and Ceylon, but should furnish a few practical hints as regards the question of irrigation, manures, and rotation.

GENERAL ITEMS.

When one cites examples of practices carried on in the West; and advises their adoption in the East, the remark is made that "it is all very well in the West, but people of the East will never be made to take to it," or "the thing is not practicable here," such have been the customs that have met the proposal that town sewage should be made use of for agricultural purposes in Eastern towns, as it is in Western cities. Before saying anything further let me quote the following from the *Indian Agriculturist* of the 18th July:—"The Municipal towns in the Punjab are realizing a steadily growing income from the sale of town sweepings and manure. From the several annual sanitary reports it is to be gathered that the sums realized have increased from R89,483 in 1886 to R1,20,790 in 1890, and the field must still be a remunerative one; for it is reported that in many places a strong prejudice exists on the part of agriculturists against utilizing sewage as a manure. The sooner this prejudice disappears the better for both the municipal coffers and the agriculturist as a common gain must fall to both. At Umritsur, for instance, there was once a prejudice; now practical experience having shown the cultivator the value of sewage as a manure, there is eagerness to obtain it, and last year the Municipality realized R3,168 from this source. At Peshawur, too, there is a demand, and other Municipalities would do well to create one. In this connexion it may be remarked that the exportation from the country of animal bones in large quantities has attracted attention, and an endeavour is to be made to restrict this exportation by inducing the zemindar to use this valuable fertilizing substance which lies at his very door in the cultivation of his own land.

The *North British Agriculturist* in reviewing Warrington's Chemistry of the Farm—the textbook in agricultural Chemistry for the senior class of the School of Agriculture, says:—"Warrington's chemistry of the farm is one of the most useful and most popular handbooks on agricultural science that have been issued, and any one who makes himself master of all the facts in this half-crown manual of agricultural chemistry, will then have as accurate and complete a knowledge of the scientific principles of agriculture as would be acquired by attending a complete course of lectures on the subject by many a professor in our universities and colleges. The fact that 27,000 copies of this handbook have

already been sold is the best possible proof of the usefulness and popularity of Mr. Warrington's manual."

Panebutano is the name of the shrub, the extract from the root of which has been found a good substitute for quinine.

"The Rural Economy and Agriculture of Australia and New Zealand" is the title of Professor Wallace's new book which is just out. The volume consisting of four or five hundred pages, is furnished with ten maps, 90 full-page plates, and 24 text illustrations, and is priced at one guinea. The publishers are Messrs. Sampson Low, Marston & Co., London.

Following the experiments of Fetchner in applying electricity to vegetation, a Russian agriculturist, M. Spechnoff, is reported to have made a trial of seeds, which he electrified for two minutes by means of a current and repeated the operation ten times upon peas, beans, rye, &c. He found that, as a rule, the electrification of seeds nearly doubled the rapidity of their growth. He then tried to electrify the earth, and the effect of the continuous current upon the vegetation is said to have been very marked. Aradish grew 17.3 inches in length, with a diameter of $5\frac{1}{2}$ inches, and carrot 10.6

inches in diameter weighed 6.6 lbs. The harvest was in all four times superior to the ordinary for roots, and two or three times for plants, and the extra growth did not appear to affect the quality of the roots or plants in any way.

Our thanks are due to the Editors of the following publications for copies of their latest issues:—St. Thomas' College Magazine, Richmond College Magazine, Jaffna College Miscellany, Hindu Organ, Jaffna Patriot, and Catholic Messenger.

We have also to acknowledge with thanks copies of the Journal of the Society of Arts, the Agricultural Gazette of New South Wales, the Agricultural Journal of Cape Colony, and Bulletin No. 21 of the Agricultural Department of Madras, and Kew Bulletin No. 43.

The husks of maize or Indian corn are now being used in the making of some kinds of paper in the United States. They are first made to yield a glutinous substance by treatment with boiling caustic soda, and this paste is separated from the fibres of the husk by a hydraulic press working over a finely perforated bed plate. The glutinous matter is passed through the machines in the usual way and made into paper, while the fibres are sold for use in other industries.

THE
TROPICAL AGRICULTURIST
MONTHLY.

Vol. XI.

COLOMBO, OCTOBER 1ST, 1891.

[No. 4.]

MR. DAVIDSON OF BELFAST ON
CEYLON TEA.

THE great siccio manufacturer and advocate of low temperature combined with powerful draught of air in the manufacture of tea has returned to Colombo and is about to leave the island, after a visit to our principal tea districts, during which he saw the leaders of the tea enterprise and explained to them the principles of his low temperature method. This method, it must ever be remembered, requires the existence in connection with a factory, of ample power to produce a strong down-draught of air. Without this down-draught where low temperature has been adopted, the result of which some have complained, of the tea being "stewed" is inevitable. Some have talked of having adopted low temperature, instancing 180°. Mr. Davidson refuses to regard a heat of 180° as low temperature. His figures are 150° for the furnace heat and 130° for the evaporating tea, the leaf, as we indicated in our previous article, being finished off in a separate drier. In an early number of the *Indian Planters' Gazette*, Mr. Davidson's views, as reported by an interviewer and corrected by Mr. Davidson himself, will appear in a detailed and authenticated form, and we shall not fail to submit the report to our readers.

Meantime we may mention that Mr. Davidson has somewhat startled us by stating that one result of his visit to the Ceylon tea districts is, the conviction in his mind that ALL our teas may be classed for quality as "high-grown." He adduced the case of the Kalutara district, where the tea is generally planted amongst rocks up the sides of more or less steep hills. To our natural remark that the heat reflected from the

faces of the rocks ought, by increasing the temperature, to give the teas thus grown a more than usually low (which means hot) country character, his answer was that the cooling down of the rocks during the night and of the temperature generally was, probably, in proportion to the excessive heat during the hours when the sun gave out his heat as well as his light rays. In any case, as an experienced tea expert, his judgment is, as we have stated, that, on the whole, the Ceylon teas, from sea-level to 7,000 feet altitude, with degrees of difference of course, have all of them the properties attributed to high-grown teas.

TANNIN IN TEA.

If our London correspondent has rightly understood what was remarked to him upon the above subject by Mr. John Hughes, the well-known agricultural chemist, the ideas which many persons have entertained on the subject of an excess of tannin in teas must be somewhat modified. Of course we do not mean to say in this respect that a very large amount of tannin in tea contributes to its wholesomeness, but that it seems now to be contended that the higher the percentage of it that certain teas contain, the higher will be the price that they will bring in the London market. Mr. Hughes is reported to have said to our London correspondent that he felt satisfied from what he had observed of the practice of London tea-tasters that the judgment of these latter gentlemen was almost invariably founded upon the relative presence or absence of tannin in the teas submitted to them. It seems according to them that tannin is the source of *strength* in tea, and that motives of economy lead the home public to purchase teas warranted to possess that strength in preference to those which are described as weak, solely because, according to Mr. Hughes' judgment, they are deficient in tannin.

Many persons will regard this view, which confirms that of the Madras Government quinologist, Mr. Hooper, founded on analyses of Indian and Ceylon teas, compared with selling prices, as a novel one, and one which if it can be supported must materially modify the principles hitherto ruling in the selection of tea. With regard to this probability we shall look forward with some anxiety to the decision of the Committee of our Planters' Association with respect to the offer made by Mr. Hughes to prepare a set of analyses of different teas. That offer has for a long time been held in abeyance by our local body; it has been actually supposed that the disinclination to accept it and act upon it

has been caused to some extent by a doubt upon the special subject of tannin in tea and how far local interests might be affected by the publication of full information respecting it in regard to Ceylon teas. But we are now informed that the Tea Committee of the Ceylon Association in London has passed a resolution requesting our Planters' Association to act upon Mr. Hughes' advice and have the analyses proposed by him made. It seems certainly desirable that this matter should be examined into as closely as possible. The view adopted by Mr. Hughes, that the higher the proportion of tannin in tea the more it is valued in the London market, may tend towards considerably modifying the opposition said to have been heretofore felt to make public the exact proportion contained in the teas of our island growth, if such opposition has really existed.

Now, however great may be the proportion of tannin in some of our teas, it by no means follows that it is necessary that the drinkers of these to whom it might be injurious or disagreeable should imbibe it. Tannin is said to be scarcely ever present to any extent in the first cup of infusion obtained from tea if the time allowed for the tea to stand be limited to some three minutes or so only. It is the second cup, after the leaf had been subjected to the influence of the boiling water probably for some ten minutes or so, that contains the tannin extract. This fact is commonly recognised by tea drinkers, and a larger proportion of milk is given to this second cup than is supplied with that of the first infusion drawn off. By a few persons, perhaps, the second cup is that most appreciated, but these bear, we should say, but a small proportion to the whole army of tea drinkers. We do not ourselves pretend to say whether Mr. Hughes' view is right or wrong; but if it be the former (as we incline to believe) it is desirable that we should know it, as it might most materially affect the question of demand for our teas in European countries.

There is another point which seems to have been stated by Mr. Hughes that will obviously call for consideration. He deems it to be desirable that the samples he may be called upon to analyse should be selected on the estates, and fresh from the curing operations, to be at once packed in hermetically sealed tins and sent home to him. We should naturally conclude from this that Mr. Hughes regards it to be a fact that our teas as now packed, transported and bulked in London undergo a certain modification of their characteristics during those operations. But what are we specially seeking as the result to the proposed analyses? Is it not to obtain a guide as to what teas are best suited to the varied tastes of home consumers? If so, and in that case, it would seem to us to be desirable that the analyses should be made of teas as they are delivered to those consumers, and not as they come fresh from the operation of curing on the estate? However, as to this we must leave decision to those of more experience than ourselves; though unless good reason can be given, it would seem as if any result to be obtained must be fallacious, if the tea as submitted to analysis and the tea as delivered, in London, is to be tea possessed of different characteristics. Double analyses would seem desirable indeed, of the teas as freshly manufactured and specimens of the same teas when they reach the London market. Now that the question has assumed the important phases we have described, the clearing up of the points now in dispute must be more than ever desirable.

NEW FODDER PLANT.

Mr Hart (at the meeting of the Trinidad Central Agricultural Board,) said Mr. Henry Warner had given notice of a question between this and last meeting. It was:—"To ask the Government Botanist whether the new fodder plant spoken of so highly in the *Tropical Agriculturist*, of 1st January, 1891, and called therein the *Lathyrus Sylvestris* is known to him, and whether he is aware of the existence of these plants in Trinidad or not. If not growing in Trinidad at the present time does the Government Botanist intend to introduce into the colony or has he already taken steps to this end?"

Dr. de Verteuil: Is it a grass?

Mr. Hart: No. *Lathyrus Sylvestris* is the plant in question, it is nearly allied to *Vicia* or vetch. It is dispersed a lover the globe chiefly in temperate climes or the mountains of the tropics. A variety of *Lathyrus Sylvestris* is the "everlasting pea," which is cultivated in European gardens for the sake of its flowers. It appears that in Ceylon they have been planting a variety of species, and some one has been writing about it in the *Tropical Agriculturist*. I have not had an opportunity of seeing this article or looking it up, as the question was only to put to me this morning; but I may say this that I do not think a European plant would be likely to thrive in the tropics. Some years ago the vetch which thrives in European countries was introduced into Jamaica, and had now become acclimatised there. It was naturalised on the hills but it would not grow on the plains. It ought to be known whether such plants would thrive here, and we might procure seed and try it, but I don't think the trial will be attended with any amount of success. Sir Joseph Hooker gives *Lathyrus Sylvestris* as a native of Great Britain and South Europe.

Dr. de Verteuil: I think it will do better in Southern Europe than in this climate.—*Trinidad Agricultural Record*.

RICE IN JAPAN.

The absence of trustworthy statistics showing the progress of sericulture, tea production, and rice-growing since the restoration, is often lamented by persons interested in the trade of this country. Some general facts are known, but it appears to be exceedingly difficult to obtain exact returns. Recently the *Nipu* published an interesting statement giving a rude idea of the development of rice culture since the close of the sixteenth century. In 1598 (third year of *Keicho*), we read the area of land under rice was 1,311,000 *cho* (3,277,000 acres), the produce of which aggregated 8,500,000 *koku* (94,905,000 bushels), being at the rate of a little over 29 bushels an acre. Out of this amount our contemporary asserts that no less than 12,000,000 *koku* had to be paid as taxes, namely, two-thirds of the whole produce—but we can scarcely credit this figure. A century later 1650, when the country had enjoyed peace for a hundred years and the Tokugawa dynasty was firmly established, the yield of rice had increased to 25,860,000 *koku*, a difference of nearly 10 per cent. Thenceforth until 1832 no statistics are given, but in April of the latter year we are told that accurate returns gave the total produce of rice as 30,558,917.84 *koku*, from which it appears that the increase between 1650 and 1832—a period of 142 years—had been only 13 per cent., against an increase of 40 per cent in the previous 100 years. Fifty-six years later, 1888, the area under rice cultivation was 2,685,886 *cho* (6,714,715 acres) and the aggregate produce was 88,645,583 *koku* (198,251,840 bushels), or a little over 29 bushels an acre. Thus the increase in this period was 26 per cent., a fact bearing significant testimony to the prosperous condition of the country during the past half century. It was natural that in the decades immediately succeeding the termination of the long era of internecine war which the *Taiko* and the *Shogun* Iyeyasu brought to an end, a great impetus

should have been given to agriculture and industry. Yet we find that in the first century of the Tokugawa rule the relative increase of the rice crop was only 40 per cent., and the actual increase 7,300,000 *koku*; while in the period of fifty-six years from 1832 to 1888, the relative increase was 26 per cent., and the actual increase 8,086,968 *koku*. It is interesting also to note that these figures furnish an apparently trustworthy estimate of the productiveness of Japanese soil for purposes of rice culture, the average yield over the whole country in 1598 and in 1888 alike having been 20 bushels per acre. Perhaps we may add that the figures show also how uniform have been the methods of the Japanese farmer during the past three centuries.—*Japan Weekly Mail*.

NOTES OF A TRIP TO THE LAND OF THE INCAS.

Panama, 19th June, 1891.

My dear —,—There is no doubt good Bishop Heber unwittingly libelled Ceylon,* but his lines—
Where every prospect pleases,
And only man is vile,

might most appropriately be applied to Panama. I do not believe it would be possible to find on the face of this earth a more repulsive lot of cutthroats than the people who at present inhabit this isthmus—a legacy left to it by Lesseps. Ten years ago the degenerate scum of all nations seemed to flock here to help to spend the Frenchman's money. Never before was such gigantic corruption, depravity, and swindling heard of. The sequel we now see in palatial buildings abandoned, thousands of ponderous machines, tens of thousands of trucks and barrows, iron bridges, and stupendous dredges all rusting in the malarious jungle. Acres of iron cottages now tenanted only by vermin or the hungry-looking ghosts of canal labourers. One spot I visited also told its sad tale the cemetery situated near Panama, an ample acreage, but crowded to overflowing. On the right as we drove along were the remains of the common dead, the little wooden crosses being simply numbered and dated, chiefly 1883-4; on the other side a smaller enclosure contained mould of an apparently more select kind, the marble and Aberdeen granite headstones testifying to the goodness, greatness, or prowess of the departed.

But a considerable number of the old canal employes still remain, some of the Europeans being employed on the railway, the nondescript heaven knows how! though doubtless the robbery of passengers forms their most lucrative occupation. On the arrival of every boat down rush the motley crowd, and lot them but once point a finger to your luggage and down must go the dollars or a bowie-knife fight ensues. No objection porters here; no policemen visible; even the stationmaster has to be bribed to let you have your ticket in time for the train. The worst loafers at Eastern ports are angelic creatures compared with the dreadful infidians who swarm in this country. And yet it is a very lovely country; the more I look at it the more interested and enchanted I am, though its deplorably bad name is enough to frighten anyone. Over and over again we were warned not to stay a night here, but it does not take long to find out other causes for its deadliness than the climate—chief

among which are dirt and bad drink. Their drinking wells are a perfect "sounner": not a drop of decently pure water to be had. And yet about 100 inches of rain per annum—the purest distilled water—is poured upon this favoured land from the Atlantic and Pacific five times as much as Australia gets, and four times as much as on the East of Scotland. And yet they have nothing to drink! You remember that for two years the purest and best water we ever had was distilled water from the Pacific. As to the climate, as far as I can judge or learn from the more intelligent of the inhabitants, it is neither better nor worse than that of Colombo, though such is its repute that we may not say so in Ceylon! The soil is infinitely better than the average of Ceylon, and the vegetation proportionately good. The curious thing is the number of plants common to both countries, many of which must, of course, have been introduced here, the Mangoe tree, for instance, growing so luxuriously and bearing so enormously, the Coconut, the Breadfruit, Plantain, and Papaw, the Oleander, Shordower, and all the variously beautiful Crotons, &c., &c. Coffee I saw none of but feel sure it would grow and bear well. There is an impression abroad that this Central America is a barren, insalubrious strip of land—lashed and blown by both monsoons. It is nothing of the kind, and, other things being equal, I should not hesitate about forming a home on yonder hill's sheer rise to 3000 feet above sea level.

Panama, in short, unlike some other places I have visited, is, as regards the climate, soil, and productiveness, better than it was painted. If such be the case—and I believe it is—generally of this isthmus, how, it may be asked, came our countrymen to such utter grief with their Darien scheme? There were various causes for this failure beside the fact that they were unsuited for labouring in the tropics—the chief reason being the herds of ruffianly Spaniards that periodically attacked the unprotected colonists justly attacks, which, we fear, were only winked at by our English friends of that day, who were really jealous of the ambitious Scot. They have come to know us better now, but I have never been able to quite forgive our southern friends for this perfidy. The same drawback may be said to exist still, viz. the want of protection and a civilised Government; but the day must soon come when, situated as it is, Central America will prove itself one of the most valuable and productive spots on earth, and poor Paterson to have been 100 years ahead of his day. The bay in which I now write is indeed a thing of beauty, the deep blue, still water being literally studded with little gems of green islands from one to 150 acres in extent. Within 100 yards of where the "Santiago" is anchored is an isle exactly resembling Helen's Isle in size and shape, but the jungle is more dense and the creepers hang down in richer festoons, kissing the rising tide. If my Kodak tells the truth you will see it for yourselves some day.

The tide rises here about 23 some say 30 feet; on the Atlantic side about 3 feet. This formed one of the difficulties which Lesseps had to face, but by no means the chief.

The one insuperable difficulty seemed, after all, the impossibility of obtaining honest men as sub-contractors. The extent of deliberate swindling that seems to have taken place is shocking to hear of. Hundreds of adventurers made stupendous fortunes out of the savings of the frugal but misguided French investors.

This letter is posted in Guayaquil, the chief port of Ecuador, some description of which will follow in my next.

* Even our friend A. S. can make a slip Heber did justice to Ceylon; and recent developments of murderous crime gives us pause in supposing that he libelled the people when he characterized them as vile.—Ed., T. A.

Guayaquil, 23rd June, 1891,

My dear —,—Guayaquil, from which I now write, is the chief commercial city of Ecuador—so called, of course, because it is on the Equator. The city, which is on the west bank of the river of the same name (properly, the Guay), is sixty miles up from the sea, so that we have had an opportunity of seeing a good deal of this very beautiful and interesting country. The Guay is a noble river about four miles broad up to this point, by far the largest river falling into the Pacific from South America. It rises at the base of Chimborazo (21,420 feet high), which mountain, being only about fifty miles from here, is seen clearly when there is no mist. This, I am sorry to say, hangs thickly over its conical top to-day. A grand sight it must be to see a snow-topped mountain in the tropics. The town looks exceedingly well from the river, the houses being exactly like the better style of buildings in Colombo, only rather higher and brighter and either white or marble coloured. Trams ply constantly along the streets, and hundreds of telephone wires indicate that it is no mean place of business.

We no sooner landed, however, than my friend and I were sadly disenchanted, the buildings being, as a rule, mere "wattle and dab," plastered and painted according to taste. The streets are too horrible to describe. The manure of half a century seems to have accumulated on them. No macadamising, the rails being simply laid amongst muck and weeds. No other vehicle can be used. The public wells are in the middle of the street, on a level with the gutter, and this in one of the hottest places in the world! How the people live at all is a mystery to me.

The population may be about 50 000, and though they do not look a very noble or healthy race I am bound to say I have seen much worse, and rarely seen quieter people. No one spoke to us as we dawdled leisurely along the so-called streets; not a single beggar asked for alms, nor a newspaper boy pestered us with the "latest edition."

The country around is very luxuriant; every acre on every hill as far as the eye can reach is clothed in dense forests. From the top of a conical little hill at the upper end of the town there is a charming view of the river and surrounding country. We met with one cacao planter, who has estates eight miles up the river. His returns are, he says, 15 cwt. per 1000 trees—says 5 cwt. per acre. He seems well satisfied with this result. The language is altogether Spanish, and we already feel somewhat at a loss for an interpreter.

The chief exports from here appear to be cacao, coffee, sugar, rubber, plantains, cattle, hides, &c. The chief officer tells me they take on the ship an average of 7000 bags cacao (210 lb. each) every fortnight, and about 2000 bags of coffee. My interpreter made one curious slip in speaking to the hardy-looking planter before alluded to. I was anxious to obtain some information regarding their system or mode of planting. "The donkeys plant nearly all the coffee and cacao in this country!" he said. He evidently thought I looked somewhat sceptical—and it was unfeigned. "Yes, yes," he continued, "those human-being-like beasts you call donkeys, they eat the fruit, drop the seeds, and there they grow." "Ah, I see: monkeys he means!" We took the address of this prosperous proprietor, and mean to visit him and his estates on our return. He has just had a trip home to Europe after a spell of forty years' work here, and he looks quite good for other thirty.

The mors I look at this land the mors forcibly does it strike me that, as regards the tropics, the Briton has by no means got the best of it. Apart from India proper, what are all our Sierra Leones, Guianas,* West India Islands or North Australia compared with this magnificent and salubrious, though sadly mismanaged country?

We saw some very excellent coffee in the market—a fine, long, close bean, fairly well cured. Just before leaving, Chimborazo very obligingly showed his sugar-loaf-like head. It was only for a few minutes, and we left duly grateful. But a greater joy awaited us. While sailing down the river just before sunset the clouds cleared away from the snow-capped crown of the Andes, and low mountains piled upon mountains to the skies; my first peep of Peru, before which I fall dumb! Any mere words of mine would be sheer mockery. I can only ejaculate with Carlyle when he looked on the starry heavens, "It's a sa'r sichts!"† or with the Turk, "God is great!"

—Aberdeen Free Press.

ARTHUR SINCLAIR.

THE WORLD'S INDEBTEDNESS TO CHRISTOPHER COLUMBUS.

The great international exposition which is to open at Chicago in the spring of 1893, in commemoration of the discovery of America, will undoubtedly be the greatest exposition of the achievements of genius and industry the world has yet seen. Within its extensive area will be found an epitome of the industrial progress of four centuries. In its catalogues and other records, in its reports and in the learned dissertations of the science congresses which will be held during the time it is open, will be formed the materials for a history of the material progress of mankind; of the manner in which the great discoveries of modern science have contributed to the prosperity of nations and to the comfort and happiness of the people. Time and history and progress are continuous, but we may divide them into periods. We now approach the end of the first great period of intelligent advancement. Out of the ignorance and superstitions of past ages has grown the sure knowledge of this closing century. So, the wisdom of today may possibly be the foolishness of centuries to come. But we think we build now on more solid ground. The four centuries that have passed have recorded their full share of ignorance, surviving from past ages and the great advances upon which we pride ourselves are, with scarcely an exception, less than a hundred years old. Therefore, the coming celebration appropriately marks a point in the history of civilisation, from which we may date a new era, of even more rapid discovery and advancement.

The genius of the American people fostered by the new conditions of life and the stern necessities of their pioneer ancestors, has contributed much to the comfort and prosperity of the civilised world. But apart from this, the discovery of the American continent has had a greater influence upon the world at large than most people imagine. The indigenous products of the soil alone, have proved of immense value to the people of every clime, and in at least one instance have provided what is now the staple food of a distant country.

* Guiana is part of South America and from what we have read about it, un-urged for fertility.—Ed. T. A.

† The version we have seen is that Leigh Hunt descending on the cheerful look of twinkling stars and shining constellations Carlyle's response was, "Eh! ma', but is a sa'r sichts."—Ed. T. A.

It may be questioned whether the introduction of the potato into Ireland has been an unmixed blessing to the Irish people, but there can be no question as to its popularity among them. The "Irish potato," however, is really the American potato. When America was discovered, the *solanum tuberosum* was under cultivation in South America from Chile to New Granada. The Virginia potato came from Peru or Chile. In 1585 G. Thomas Herriott, a companion of Sir Walter Raleigh, carried the potato from Virginia to Ireland. It was introduced into Europe by the Spaniards in 1555.

The sweet potato, now such an important production in Japan and China, is supposed to have originated in South America. In the year 1610 the *bataia*, by which name it is known to the Malays and Portuguese, reached China from Luzon. From here it was introduced into the Likiur Islands, and thence, in 1698, the King of those islands sent a basket full to the Daimio of Satsuma, who caused them to be planted on Tanega-shima. Thus the culture was established in Japan, where the familiar name *Satsuma imo* recalls the place of its introduction.

The history of the many varieties of beans grown in the Far East is scarcely known. The common haricot bean, now found almost everywhere, the lima bean, and the sugar bean, are all of American origin. The haricot bean is of very ancient growth. It was used by the Peruvians in prehistoric times. Specimens have been found preserved in their ancient graves. More recently Dr. Wittmarck, of Berlin, identified this bean among some specimens obtained from prehistoric tombs in Alaska, specimens which the writer of these lines saw in Dr. Wittmarck's hands, while the investigation was in progress.

Indian corn is another product for which the old world is indebted to the new. The oldest specimen of corn known was discovered by Darwin, in the soil of the Peruvian coast, at an elevation of 85 feet above the level of the sea. How old that is may be a matter of mere speculation. It was preserved in the dry soil for ages.

The tomato is also a native of Peru.

Tapioca is obtained from the starchy manioc shrub, indigenous to Brazil and the West Indies. The flour, known as cassava meal, had long been in use before the coming of the Spanish and Portuguese. The true West Indian arrowroot had also been long under cultivation in tropical America at that time. The squash and pumpkin also appear to be strictly American productions.

The cocoa tree which furnishes cocoa and chocolate was highly prized by the natives when America was discovered. It was under most careful cultivation, and already naturalised in Central America and Yucatan. It was probably introduced from New Granada. The Spaniards found the custom of drinking chocolate quite general in those countries. When the seeds were sent to the Mexican highlands, the people valued them so greatly that they used them as money. The cocoa and chocolate production of Central America and Mexico is now of great commercial importance. The sweet cacao butter, so highly prized in pharmacy because it never becomes rancid, is obtained from the seeds, being partly removed in the preparation of cocoa.

One might extend this list of food products to include many others, principally productions of tropical regions, which are not so commonly known. There are numerous nuts and fruits which are delicious, either fresh or preserved. The guava is one of these; but there are more important products to be mentioned. Coffee is not distinctly an American product, but two-thirds of

the world's supply comes from South and Central America and the West Indies.

Caoutchouc or Indiarubber was first discovered in South America. Some specimens were taken to Europe about the beginning of the 18th century, when its valuable qualities were soon recognised, but for a long time the secret of its origin was not revealed. South America still furnishes one-half the world's supply, the greater part of the remaining half coming from Java.

The coca or coca of Peru is a most valuable tonic, known and used very largely in Europe and America. It is said that the natives chew the coca leaves to give them strength and endurance. They can then perform long journeys without food or rest.

The benefits derived by the world from the alkaloids of cinchona or Peruvian bark, can scarcely be overestimated. What would we do without quinine? We buy it in quart-ounce bottles, but it is manufactured by the ton! The cinchona bark was first brought from South America in 1639.

America has been a large contributor to the commerce of the world in other productions not peculiarly her own. There are immense forests which yield an inexhaustible supply of valuable timber, there are cochineal and other dyes, vanilla beans, and innumerable bananas, pineapples, oranges, and other fruits. The fine, long staple cotton of the Sea Islands, which fringes the coasts of Carolina and Georgia, is produced nowhere else in equal perfection. The first bale of that cotton was shipped to England from St. Simon's Island in 1788.

The resources of South and Tropical America in textile fibres are by no means developed. Pita and hen-quan ore produced in Mexico, sisal in Yucatan, and nobody can tell what importance these, and other fibrous products from the great variety of agave—a type of which is the common century plant—may soon attain. The West Indies furnish enormous quantities of textile fibres—more than can be at present utilised. South America is rich in possibilities of the same kind. Some of its palm fibres are of great strength and value; as those from the *mum* for example, of which the natives of Bahia make their fish-nets. The streets of London are daily swept with brooms of the *piassaba pilna*, a product of Brazil.

Thus we see how the discovery of America has led to results of worldwide importance. Not only has it increased and cheapened the food supply of the world, and added to our resources in many ways, but, by opening new territory for settlement it has also relieved the countries of Europe from the perils of over-population. The increasing struggles of a close and growing populace for the necessities of life, inevitably lead to grave social difficulties; finally to wars and revolutions. Is it too much to say that emigration has preserved Europe as it is?

It is therefore appropriate that the American people should celebrate the great discovery of Columbus, in 1893, and that they should invite all nations to participate in an international exposition of arts and industries, which shall represent the highest ideals of our civilisation, and the course of their development. —*N.-C. Herald.*

HORTICULTURE AND LANDSCAPE GARDENING

Haputale.

Gardening is steadily and surely progressing. The horticulture of the present is no more like the horticulture of the past, than the Post Office service of our own day, or means of communication or locomotion generally, are like to what either of them was thirty years ago. There is a general activity pervading the immense hive of human industry. Even

those of an indolent turn of mind, are pressed onward in the ceaseless hum. Commercial transactions are entered into and accepted now, thousands of miles apart, with as much promptness and celerity as they were between districts not tens of miles apart, only some few years ago. Opposition in trade, rivalry in production, and facility of despatch have indeed quickened the *genus homo*, and wealth and affluence have consequently been the outcome. The "good old times" about which we have heard so much have given place to better; luxury and social comforts have increased to a degree, and to such an universality, as furnish the most convincing and eloquent proofs of the progressive developments of mental endowments. Like Voltaire, we are thankful that we have the good fortune to live in this age, independently of the consideration that it is better to be still alive than to have lived. As regards the progress of horticulture, there is a marked change, and we are in a position to say, that each year will see its progress by rapid strides. Horticulture is wealth the wide, wide, world over. It is not a treasure hid under a bushel, but gives abundant riches, and there is still some more to follow. Wealth has grown, so has horticulture. Every cottager has his bit of garden wherein he grows his herbs for his soups, and his vegetables for the table. It is one of the "good things" of this life which a good God has given to the use, joy, and benefit of man. The proper cropping of a garden, with little expense, will supply a whole household, of all classes and of every grade. Horticulture is enlisting into her army hundreds of volunteers every year. Her dominions being large, with such a diversity of subjects, that persons of every grade, white or black, is induced to take a greater or a lesser interest, in a less or greater number of these subjects. Time is even now, when certain classes of the people will not part with a few rupees, two or three at most, to buy a few vegetable seeds to crop a two-acre plot of good land, and command a good selection of choice vegetables, they are afraid they might overrun themselves, and incur an expenditure beyond the annual income of their means. A gentleman with an income say £150 per annum and upwards might have a good garden and enjoy the luxuries of plant life. If even they take the responsibility of doing the light labour, it is wonderful what an amount of gay flowers, and tempting fruit, and rich vegetables they could command, without incurring an awful large expense, than they can well afford. As to the quality of vegetables they are no better now than in the time of our forefathers. What we excel in, in our own days, is that we draw largely from our own resources, and provide a longer season of fruits, vegetables, and flowers. The demand for Nature's productions are great, and consequently, as in other branches of human industry, we have done all that is possible to be equal to the occasion. Our gardens and our fields have been enriched by collections of fruits, vegetables, and flowers from every region of the known earth. Hybridists and cross-breeders have been at work to improve the form and alter the character of everything likely to take the market. If there is an introduction of anything new, that is likely to weigh well, there is a rush for that one thing, and the consequence has been it has overrun the market. The boards have been overstocked, and the whole thing has almost been a smash up. If it were desirable to prolong the season of anything that the garden is capable of producing, what pains, what attention, is manifested, and in course of time, probably after a series of reproductions the article is forthcoming. If anything new is imported of an almost abnormal kind, if it were of a little more than ordinary prominence, which if it is likely to take the market, the rapidity with which it is propagated would startle and surprise a practitioner living in the first quarter of this present century, it would have caused them to scratch their heads with astonishment. To be backward with anything now in the way of horticulture is a thing of the past; much could be said as regards the things of the past, how they were done, and how they look now, but I will keep off that subject at present; at any rate suffice it for me to

say we can laud past operations. Business in horticultural matters is like business in other matters, it gives quite a different tone in these days. There is no apathy, no rest during business hours, no hoping, no dreaming, no sleeping; but all is enthusiasm, ingenuity, and push, as greatly different in character as the railway is to the uncomfortable, clattering, noisy old stage coach. Horticulturists of the right nature are animated by the same feelings, and are carried along in the onward march of progress. As Shakespeare says "all the world's a stage," and each man in his turn plays some particular part," and the horticulturist performs his own part well. First of all let us see what has been done and is being done in landscape gardening—we might ask where does it begin? and where does it end? All depends upon the scenery at disposal—the site—the climate—and the character of the mansion. With the material placed at our commands within the last quarter of a century, it would be a pity indeed if we could not leave some very distinct examples of high taste, as an heirloom to posterity. We have a grand and wonderful variety of form and colour in our nurseries to assist us in laying out and clothing our landscapes with all that is beautiful and interesting in tree life. This leaf-growing country which is rightly named, which is famed by gentle and "spicy breezes" which breathe out spicy odours, and enbalm the air with delightful perfumes, how the estates of this colony could be made effective and interesting, as well as producing good returns. What is more advantageous to the tea and coffee shrubs than good wind-belts, as a screen against rough and disastrous winds? Trees of a coniferous nature will produce a good effect wherever placed. Our forefathers had a limited catalogue to select from, but now there is no end to the species presented to us. They are almost compelled to hold hard and fast by a natural size, for the numbers of formal evergreen tree and bush life were very limited. We are compelled now, out of the collections of trees and shrubs found in our nurseries, to put on as fascinating appearance in our parks, pleasure grounds, and public gardens, particularly about the foreground where the highest art is centred, so as to reach a high degree. We can well imagine Knight, Price, and Gilpin, and others of the same school, crying aloud for the picturesque and the things natural in themselves. If they had lived in our own times, it is highly probable that the quantity of materials presented for landscape work of all kinds, and the variety of form and feature which these materials assume, would have brought a considerable change in their views. Their great aim was to create a landscape about which a painter would get into an ecstasy.

In the first place, what is most beautiful in nature is not always capable of being most represented, most advantageously by painting; the instance of an extensive prospect, the most affecting sight the eye can bring before us, is quite conclusive. I do not know anything that does, and naturally should, so strongly effect the mind as the sudden transition, from such a portion of space as commonly have in our minds, to such a view as the habitable globe as may be exhibited in the case of some extensive prospects. But in the expanse, the beauties of nature itself, and which painting can exhibit, are many, and most of them probably of a sort which have nothing to do with the purposes of habitation, and are even wholly inconsistent with them. A scene of a cavern with banditti sitting by it, is the favourite subject of Salvator Rosa; but are we therefore to live in caves, or encourage the neighbourhood of banditti?—Gainsborough's country girl is a more picturesque object than a child neatly dressed in a white frock; but is that a reason why our children are to go in rags? This is just the proposition which some maintain in the contrast which they exhibit of the same place, dressed in the modern style, and left as he thinks it ought to be. We are not living in caves, and rocks, and dens of the earth; but in God's beautiful universe. To me there is nothing more appalling than the walls, fountain basins, clipped trees, and long canals as in Versailles, not only because they utterly fail to satisfy in themselves, but inasmuch as they are ever

accompanied by a day-ghost of wasted effort, of riches worse than lost. If basins, and fountains, and statuary are not "in keeping" with the grand and spacious grounds of our Crystal Palace, or the beautiful and lovely gardens of Versailles, of which the Parisians are justly proud, then where are we to find a place for them? Are these Grecian piles of architecture, with their noble array, of Doric or Ionic, or Corinthian columns, to be surrounded with natural scenery without even one attempt to produce a groundwork more in accordance with the character of the pile? Are terraces and a mixture of statuary and fountains, in connection with geometric designs for flowers, not the very things that give a charm, a character, and a framework to such beautiful habitations of men?—Is "Paxton" on the one hand, or "Le Notre" on the other, to be condemned because their works bear witness to an appreciation of much of the elaborate style of ornamentation, of desire for scope of grass, and gravel, and riches of statuary, and squirting fountains? Certainly not! Their genius and their work was appreciated, and will be in the time to come. Places are not to be laid out with a view to their appearance in a picture, but to the uses and the enjoyment of them in real life; and their conformity to those purposes is that which constitutes their beauty. With this view walks of crushed stones and white pebbles, gravel, and asphalt, are all well in their places. And neat lawns, straight cut alleys, fountains, terraces, and for aught I know, parterres and cut hedges, are in perfect good taste, and infinitely more conformable to the principles which form the basis of our pleasure in these instances, than the docks, and thistles, rampant weed, and litter and disorder that may make a much better figure in a picture. Have your own taste of course, but let it merge a little towards woodland scenery, and form the connecting between one and the other. Your house must be the centre of observation, whether it be constructed in the Grecian or the Gothic, or the Scotch bairnial, or any other style of architecture. Your oarhwork designs must be planned, and laid out accordingly, let there be nothing done which will be a laughing-stock to the true landscape gardener. We have grand pictorial trees, such as these you see in "Paradeniya Gardens," beautiful in their individuality, and beautiful for the purposes of grouping and contrast; but they must all be placed in the right situation. The selection must be choice and suitable, according to the configurations and accessories of the place to be clothed. Where the grounds are limited, and shelter and privacy are an object of first consideration, our ideas as to fitness, proportion, and unity are considerably modified. We design and plant more in accordance with comfort than with the view of holding fast to a pet system. If you still desire being "hoded in," in this case, a living, thick, belt of trees of whatever sort is absolutely necessary; but at the same time the forefront of the house being the principal outlook, I think should always be one of far-seeing grandeur and beauty.

In accordance with the fashion of the times, the grounds in the immediate contact with the mansion or villa must have somewhat of a stylish aspect. You must have the best style of groundwork for showing off your fashionable and decorative flowers. You must have a good scope of grass, a portion of which must be invariably set apart for the game of croquet, and also a portion set apart for the bouncing tennis ball. In addition to all this (with a view to perfection) you must have a great variety of dwarf decorations—succulose and herbaceous plants, and a rockery or a rookery in some quiet nook for Ferns and alpine; in short, to be up to the times, you have to aim at a sort of "microcosm" of what is to be had in all the largest domains of our country and her colonies.

Should this letter fall into the hands of any lady or gentleman, desirous of laying out their pleasure grounds in a small or large scale, any valuable suggestion which is found therein and is made use of, and which are put into practice, the writer of the letter will be much benefited.

Haputale,

WILLIAM METCALFE,

SAMPLING IMPORTED MANURES.

It is no uncommon thing to hear of complaints being made that the results obtained on our tea and coffee estates from manures imported from Europe differ very considerably from those prophesied of them by chemical experts. We believe that as the rule it is a very easy matter for a man trained in special knowledge as to such a subject to foretell with accuracy what the effect of certain chemical combinations will prove to be on soils the natural constituents of which, with their physical condition, are known to him. When, therefore, we hear that the prognosis—to quote, perhaps not inaptly, a term usually confined to medical science—of such an expert has not been realized, we may assume it to be only fair that the cause of failure must be sought in another direction.

There is some probability that in these days of competition, and of a laxness of principle attending it, the chemical manure manufacturer may not in all cases carry out what he professes to do. He may advertise a special fertilizer to contain such and such ingredients, but it may not be always the case that his shipments to a far-off country may be always up to the standard he proclaims. Or even supposing that as regards this he acts in full good faith, it may yet be that the manure he ships has been manufactured for some considerable time, and that, should its preparation include some particularly volatile ingredient, the fertilizing qualities of the manure may have undergone considerable deterioration. The only way in which, as it seems to us, this can be in any degree guarded against is by the purchaser insisting that a competent chemist employed by him should select samples from the bulk after the manure has been put on board ship, and that on the report made after analysis by him of such samples should depend the acceptance or rejection of the shipment, or the price to be paid for it. A case has recently been under our notice in which this precaution seems to have been neglected; and although there is no proof that neglect of this precaution is to be held alone answerable for the disappointment which followed, there may be a fair presumption that it had something to do with it. For, as we have above written, an experienced chemist versed in such matters could hardly miscalculate the resulting effect to certain chemical combinations; and if those had been fully provided for, and the fact ascertained by sampling on shipment, there could be no reason why disappointment should have arisen.

We do not suppose that among the ranks of chemical manure manufacturers the proportion of honourable or dishonourable men is greater or less than among other manufacturing agencies; but as we know that the second class are unfortunately to be found in no inconsiderable measure in every rank or walk in life, it would be quite as well if our planters were to consider the necessity when ordering a shipment of manure to provide against dishonesty or carelessness by insisting upon provision of the nature we have indicated being made. For if this be not done we cannot be surprised if the not unfrequent failures that we have heard of should recur, and fertilizers which might be of most useful effect earn a bad name thereby. And it is the more important that such a precaution should be taken because disparaging comparison is often made between the effect of imported manures and that of cattle, poonac, and other native fertilizers. The latter we know are always to be relied upon, but it does not follow that they

would yield the same efficient result as would a carefully selected chemical manure, if only this could be guaranteed as possessed of all the qualifications promised for it. The attention of our planting friends may well be drawn to a subject which cannot but be of much importance to them. Whatever question there may be as to improving the natural qualities of tea by the process of manufacture, there can, we suppose be no doubt that quality even more than quantity of leaf can be greatly enhanced by the liberal and judicious application of suitable manures.

COFFEE IN COORG.

The following is a forecast of the coffee crop in Coorg for 1891-92 which is given by the *Bangalore Spectator* :—

Forecast of yield as obtained from	Europeans 2,198
Planters' Returns...	Native do
Forecast estimated for area for which no returns have been furnished...	Europeans 927 Natives 1,319
Total Forest for 1891-92...	4,444
Estimated average yield per acre of ordinary well cultivated coffee in full bearing for 1891-92...	1 cwt.
Return of export of coffee from Coorg last year 1890-91, taken from the Toll gate returns...	2,235
Return of export of coffee for 10 previous years...	38,397 tons or 3,839 tons annual average.

Taking the average or one Rupee crop at 3,839 tons per annum, the forecast of 4,444 tons for the coming season represents an 18-anna crop, the anna equivalent being 444 lb or 247 tons; but taking the average yield at 4,000 tons it comes to a 17-anna crop, which is a crop somewhat above the average, and that is what is expected this year in Coorg, a full average, but not a bumper crop.

The amount of export of coffee is put down from the toll gate returns. These are not accurate as the toll contractors, in view of the renewal of their licenses at cheap rates no doubt manipulate the returns. The annual average ought not to be less than 4,000 tons.

FRESH discoveries of tin are reported from Tasmania, and no little excitement has been created in the colony by the large number as well as the richness of the new "finds." Some new lodes of a valuable character have been unearthed at Mount Mitchell, in the Blue Tier district, and also at a place known as Nnggety Gully, north of the Wellington mine. On the whole, the tin-mining industry in the prospering colony appears to have even a much brighter future before it than was anticipated a few years since, and both men and capital are now pouring into Tasmania from all parts of Australia.—*Colonies and India.*

SUBSTITUTE FOR INDIARUBBER.—Those who are financially interested in the Para rubber trade will watch with no little interest the progress of Blandy's Patent Syndicate recently formed on this side. The statutory meeting of the syndicate was recently held, under the presidency of Mr. D. W. Wales, who stated that the object of the company was to work a patent for the use of a substitute of indiarubber. At the present moment they were in negotiation with regard to the sale of certain of the continental patents, and they were producing samples upon a large scale. The tests that the material had been subjected to had proved in every way satisfactory, and they had received testimonials as to its value. Dr. Blandy was, at the present time, deciding upon the best place for the works. Mr. Wales expressed his opinion that the syndicate would prove a very profitable investment to all concerned in it.—*E. Mail.*

A REVIVAL OF COFFEE is thus noticed in a letter from a planter:—

'It almost seems as if there were going to be—on a very small scale—a revival of coffee. When I came down here from Dimbula in February I had no idea that there was a tree left on this Estate, not a berry having been picked for at least 3 years. But I find that the few trees which have escaped in the cutting out process are all bearing heavily, and I shall get a bush or two for Bangalow use.'

"Riding up the Kadugannawa Pass the other day I saw what I have not seen for years—i.e. coffee, green, ripe spread out to dry by the road side."

COFFEE AND TEA IN PERAK.—Besides coffee cultivation, which is now in full swing and yields the most satisfactory results to the planters, the Perak Government have lately made some very successful experiments in tea planting. We already had occasion to refer to that source of Perak's future revenue, and to mention that wherever it was tried, the Perak tea leaf was highly appreciated, both here and in London. Since then an enterprising Chinaman has taken over the gardens from Government, and engaged an experienced Darjeeling planter, under whose direction he is now extending the same. We tasted some of this tea a few days ago, and must say that we found it very good; it is not so dark in liquor as the Ceylon tea, but has a very nice and pleasant flavour and good strength. Local industry always deserves to be encouraged, and we feel sure that the inhabitants of Penang will soon come to appreciate the undoubted qualities of this tea. As will be seen from an advertisement in another column, Perak tea may now be procured from Messrs. Maynard and Co., Limited, and all the leading shopkeepers of the town.—*Straits Independent, Aug. 19th.*

TEA IN CHINA.—We have the following tea news from Foochow, under date 25th July.—The calling steamers during the fortnight have been the "Ajax," "Pingsuey," "Glenavon" and "Agamemnon." They took between them 2 million lb. bringing up the export to Europe to date to 9 millions, against 8½ millions at the same date last year. The "Beaulder" is loading. The tone of the market has been quiet. The settlements of Congou are reported at 34,000 chests, a very moderate business for the time of year. The attention of buyers has again been directed chiefly to common up to good medium grades, although the tea men have been trying to make their fine teas tempting by inviting offers to be made for them. The tendency of prices generally has been downwards, excepting for common grades, which remain firm. Amongst teas which show a decline are first crop Saryunes and Sueykuts, and second crop Sueykuts, also good medium Panyongs at Tls. 46½ to 18; all may be quoted Tl. 1 cheaper. On fine and finest Panyongs a decline of fully Tls. 3 may be quoted. Souchongs are dearer. Looking at the question of total supply, the prospects, so far, are not altered, although the arrivals during the fortnight have reduced the present deficiency by some 24,000 chests. The second crop happens lately to have come in in bulk, but as it is almost finished, and is short, the large deficit shown at the beginning of the month should reappear in another week or two. The prevailing opinion amongst foreigners is, that the quotation for common must bring down large quantities from the present time, but the Chinese affirm that it will not be so, as the tea cannot be got. The arrivals of Congou to date are 259,000 chests against 317,000 chests, the settlements are 163,000 chests against 143,000 chests, and the stock is 96,000 chests against 174,000 chests at corresponding date last year.—*N. C. Herald, Aug. 7.*

"SIROCCO DAVIDSON" AND HIS NEW-EST IDEAS AND INVENTIONS IN TEA MANUFACTURE.

[The receipt of an early copy of the *Indian Tea Planters' Gazette* enables us now to quote the full and detailed account, which received Mr. Davidson's imprimatur, of his system of manufacturing tea at a low temperature by means of a powerful down draught so as to preserve the volatile oil on which flavour depends, and to impart what is said to be so much needed,—keeping qualities. Our planting readers will see that our own article in which we gave the results of our interview with Mr. Davidson embodied all that was essential in the improved process, as Mr. Davidson indeed cordially conceded. Mr. Davidson's verdict that all the Ceylon teas have the quality of high grown means that they are distinguished by delicate flavour. The more important, therefore, is it that we should omit no effort to preserve a quality, without which, Mr. Davidson's experience shows our product cannot make headway in the Continental and American markets. In the portrait which accompanies the notice of the distinguished planter and machinist, justice is done to his fine aquiline features and intellectual head. It is a noteworthy circumstance that Mr. Jackson, whose rollers are the most popular in the world, and Mr. Davidson, whose driers are equally popular, should both be of Scotch origin. The difference is that Mr. Jackson is a *pukka* Scotchman (to use the Hindustani word which occurs in the article), hailing from "Aberdeen awa," while Mr. Davidson is a *cutchu* Scotsman, having been born in Ireland. But he can claim, like another manso boru, that it was "because he happened to be there at the time." He is in truth a member of the Scotch colony in the north of the emerald isle who by their intelligent enterprise, and steady industry have proved what a different country Ireland might be, if she were relieved from the *incubi* of ecclesiastical thralldom leading to ignorance, on the one hand, and unscrupulous agitators on the other. To us it was interesting and amusing to listen to able scientific disquisitions in language rendered piquant by the delicate combination in it of a Scotch foundation accent with refined Irish brogue. It will be the pleasing duty now, we cannot doubt, of the *Indian Planters' Gazette* to include in its portrait gallery and series of memoirs as good a likeness and as appreciative a notice of the other greater benefactor of tea planters and manufacturers, Mr. Jackson, as have been given of Mr. Davidson. For Mr. Jackson it is claimed that his improved driers, specially the *Britannia*, if rightly worked, will secure all the improvement in quality which Mr. Davidson's processes are calculated to effect.

MR. S. C. DAVIDSON.

(From the *Indian Tea Planters' Gazette*.)

Most of our tea planting friends are doubtless aware of the fact that Mr. S. C. Davidson, the clever inventor and manufacturer of the now thoroughly well known Sirocco Tea Dryers, has been on a visit to the Indian Tea District since last November, and as we considered it only right that the portrait of a gentleman to whom the tea industry owes so much should be produced in the columns of the planters' only journal, we took the opportunity of calling upon Mr. Davidson when he was passing through Calcutta on his way home and just before leaving and he very good naturedly acceded to our request, went to Messrs. Bourne and Shepherd's and faced the camera

with the satisfactory result which we print on the opposite page. We further had the pleasure, in interviewing Mr. Davidson, of gathering the following interesting particulars of his career:—Besides being an inventor of manufacturing machinery he is also a tea planter of long experience, having begun his career as a planter on his own estate in Oachar in 1864 when only seventeen, and although he retired from active management of his tea property some fourteen years ago, with the object of starting a manufacturing business at home for the several machines which he had even then invented and patented in connection with tea manufacture, yet he still continued to direct the management of his concern out here, and kept himself thoroughly in touch with all the progressive improvements and details of tea estate work in general and manufacture in particular, as he sensibly considers that an inventor and manufacturer of machinery for any special industry must, to keep abreast of the times, have the growing requirements of that industry always perfectly clear to his mind; and he also holds that to excel in the manufacture of any special article a knowledge of what both purchaser and consumer look for in that article is equally necessary—hence with this view and while carrying on his machinery business, he opened up what has now developed into a large business in Tea in the United Kingdom, and had branch establishments for the same in Paris, Berlin, Munich and St. Petersburg, and on a more extensive scale in New York. He found however, that the public taste in these places was strongly wedded to China and Japan teas, and that the cultivation of a taste for teas of India and Ceylon growth was a matter of such slow and gradual development, that the sales were as a rule, insufficient to support a business exclusively devoted to these teas, so last year he reluctantly decided to discontinue these branches. He however, feels sure that the experience gained by him through his foreign trade and the investigations which it became necessary to make to ascertain the special peculiarities of the public taste in tea of such different nationalities, gave him more information as to the true value of flavour, unconsidered altogether apart from the matter of strength, than if he had confined his operations exclusively to the United Kingdom, and as a broad rule he ascertained that it is flavour and not strength that Continental and American tea drinkers look for and place most value upon. Accordingly about two years ago he began a series of preliminary experiments with some of the very finest flavored teas that he could procure of China and Darjeeling growth, to ascertain if their beautiful flavor could be enhanced by the application of any special degree of temperature in the drying process; these experiments were carried out in his laboratory, but somewhat to his surprise he found that instead of getting an enhancement of flavour from the action of any high temperatures, the reverse was the case, and that when the tea was raised above 130 deg. the very delicate flavour gradually diminished; until at 160 deg. to 180 deg. it almost entirely disappeared but so long as the tea was kept below 130 deg. it did not suffer in the least, though no improvement was effected by the heat applied; it was thus evident that the avouring matter of the leaf gradually became volatile when the temperature of the tea itself was raised to over 130 deg. and that what has got to be done in the manufacture of tea is to so dry it that these volatile constituents may not be lost. If they are lost by the employment of too high a temperature, he then found it necessary to go as far as 240 deg., at which temperature an artificial flavour known as "malty" is produced which to some extent compensates for the loss of the original pure tea flavour, but the great objection to the malty flavour is its tendency to, what the trade calls, "go off" in two or three months and hence the complaint which the home trade have of late years raised as to the non-keeping qualities of Indian teas. It thus became perfectly evident to Mr. Davidson that in the first place the flavour must be a matter of the development due to climatic effects on the growing leaf and its treatment in manufacture prior to the drying process,

while the object of the drying process must be confined to the desiccating of the leaf without driving off the flavour already developed. He thereupon got some experiments carried out for him with sample lots of leaf by some of his numerous planter friends, and the information which he gleaned from these experiments has proved so important that its outcome is the introduction now by Mr. Davidson of what promises to be a revolution in many of the established ideas and principles concerning the manufacture of our teas. One part of the system which he has evolved is for the enhancement of flavour and quality of the tea prior to the drying process and is the subject of one of his later patents. Two of the very largest of our Indian Tea Companies were so satisfied with the probabilities of the results that would likely ensue by working this special process that they arranged with him for its use, with the several patented machines which are necessary for its proper working being exclusively confined to themselves, so that we understand they are well satisfied with the results they are obtaining therefrom, yet in-as-much as this part of the process is to be confined to these companies, we cannot further refer to it; but the remainder of Mr. Davidson's investigations as above indicated we are at liberty to submit to the consideration of our planter friends, as the improvement effected by attention to the directions he gives as to the temperatures for drying have, in some instances that we are informed of, given a most wonderful improvement in the quality of the tea produced. Mr. Davidson points out that it is essential while using low temperatures that either the leaf be spread extremely thin upon the sieves upon which it is exhibited to the heat, or that if spread thick, the air draught through it should be very rapid to carry off the moisture quickly without involving any risk of the tea being "stewed." For this purpose and to meet these desirable ends Mr. Davidson has greatly increased the power of the air current through his new Down Draught Sirocco, which he now recommends being used at 150 deg. temperature for cutcha* battie and withdrawing the leaf before it is quite crisp dried, so that its temperature when tested by thermometer should not indicate more than 120 deg., and that the final drying or present battie of this should be worked at a temperature of 130 deg. Some hill teas made on these lines have a very delicious and exceptional flavour. Of course leaf grown in the plains cannot be expected to have as much flavour as hill tea, nevertheless such as it does possess Mr. Davidson says can be fully retained by following the above directions.

We understand that Mr. Davidson hopes to arrive back at his Works in Belfast about the latter end of September and although those are already extensive premises (notwithstanding their recent inauguration some 10 years ago) yet we predict that if he continues to give the same detailed and scientific attention to the improvement of tea in its general manufacture that he has hitherto bestowed upon it, their growth will be still more rapid and that a great and prosperous future is in store for him, as it is only by improving the quality of the Indian teas that the death-blow can be dealt to those of China which are still much sought for on account of the delicacy of their flavour in the high class qualities, those being still the favorite teas both on the Continent and in America.

We are indebted to the sailing of the S.S. "Goleconda" having been unexpectedly postponed from the 4th to the 5th instant for the above particulars and Mr. Davidson's photograph, but unfortunately we omitted to obtain from him any particulars of his private history, and we have now only to conclude by wishing him *bon voyage* to old Ireland for which he leaves Ceylon early next month.

TEA SHARES AND INVESTORS.

When the claim of less substantial but more freely advertised companies are in abeyance, the financial press occasionally calls attention to the financial

position of the tea industry. In its issue of yesterday, the *Financial News* had a long article on the subject, and the writer, while dealing with the position fairly, has nothing to reproach himself with on the score of undue optimism. He says: One of the features of the financial year, so far as it has gone, is the stability of Indian and Ceylon tea shares amid all the fluctuations of the other markets. For one thing, they remain outside the range of the ordinary speculator, and, for another, there are few of them quoted in the Stock Exchange list. One may hear occasionally of a movement in Jokais, which for the last seven years have been paying 10 per cent., and sometimes of a transaction in Doours, or Darjeelings, or Jorchants. The investor, however, who believes that he has a grip of good security does not usually carry his heart exposed for daws to peck at: and, on the other hand, the unfortunate persons who have dropped money on the strength of deceptive prospectuses usually maintain a cynical silence as long as they think that there is a chance of transferring their white elephant to someone else. Indian tea shares, and particularly those of the new Ceylon plantations, have been so little known, indeed, that in certain quarters the value of a new discovery was attributed to the article in the *Financial News* of February, which disabused and explained the subject from an investor's point of view. The question then was, why tea, as a commodity, should have attained so high a price as it then held, and why tea company shares should continue to be so disproportionate low. Our answer was, substantially, that many of the companies—and we were referring particularly to the Indian companies—had been over capitalised, and many others extravagantly and unscientifically managed. There were too many of them, also, which seemed to regard quantity rather than quality as the Alpha and Omega of their policy. On the whole, nevertheless, we felt free to say that, in view of the increasing demand for the "cup that cheers," there should be good prospects for investors in well conducted tea gardens, whether in Assam, or Cachar, or Ceylon. Since we dealt with the question six months ago tea shares of one description have appreciably improved, nearly all have held their own, and, at the same time, a larger number of companies have earned good dividends. Yet, even when so much is said of the past half-year's business, it continues to be the fact that tea shares are not in active demand, and are, as a rule, quoted lower than recent dividends would appear to warrant or explain.

The *Financial News* bases its calculations on the statistical report by Mr. A. W. Martin:—

Name of Company	Paid-up Capital	Dividend per cent		Return per cent on July share prices
		1889	1890

"These results," it remarks, "are taken from a list of fifty companies, some of them known by name outside the circle of their limited proprietaries. Of the fifty, twelve paid no dividend for 1890, and among the dozen are four or five which were born to a condition of impecuniosity, and, like Mr. Micawber, survive upon their hopes rather than their income; but when deductions are made on this account, and for sundry frauds or failures to which Mr. Martin makes no reference, there is a solid foundation left for the belief that tea companies are well worth looking into as investments. Meanwhile, the output of Indian and Ceylon teas has been rapidly increasing, while our import of the China leaf is continually declining. The total imports from India for the year ending with June last were 100,984,000lb. against 100,635,000lb. in 1889-90, and 94,381,000lb. in 1888-89. The Ceylon imports were 50,101,000lb. for the twelve months ending June last, as compared with 34,220,000lb. in the preceding year and 27,890,000lb. the year before. The supply from China and Japan fell from 92,519,000lb. in 1888-89 to 90,050,000lb. 1889-90 and 69,742,000lb. in the year ending in June. Tea imports from Java amounted to 4,120,000lb. in 1890-91, a considerable improvement over the 3,094,000lb. of the previous year but a decrease on the 4,297,000lb. in 1888-89. But, the most noticeable circumstance in this connection is the growth of the tea industry in Ceylon. The deliveries in the port of London have swollen from 24,904,800lb. three years ago, to 41,682,000lb. between July 1st, 1890, and June 30th, 1891, or from the rate of 2,075,400lb. to 3,706,900lb. per month. Last month (July) the import was, in round terms, 5,750,000lb and the deliveries about 5,500,000lb. It is on these remarkable evidences of development that Ceylon tea planters base their estimate that in ten years time the output of the island will reach 100,000,000lb. per annum, or as much as the import from all India today. The accounts for the last half-year have not yet been made up, and Mr. Martin's table includes only four Ceylon undertakings, of which one is the Eastern Produce and Estates Company, whose history is not exactly encouraging. Of these, however, it may be noted that the Ceylon Plantations paid 15 per cent on its ordinary shares, the Lanka Plantations 6 per cent and we may add that the Land and Produce declared a January dividend of 10 per cent.* There are, no doubt, rocks ahead of the British tea planter, and one of them is indicated in the figures we have quoted with regard to the increase in the volume of imports, both from India and Ceylon. Mining Lane rates are not what they were six months ago, and prices have approached nearer to the narrow margin which represents profit on the cost of production. The general consumption does not seem to have diminished. The home demands for the eleven months up to May last was estimated at 100,000,000 lb. Indian and 40,000,000 lb. Ceylon, against deliveries during the twelve months ending June of 96,456,000 lb. Indian and 42,853,000 lb. Ceylon. But it is a moot point whether the output of British-grown tea, encouraged by a demand which was stimulated by low prices, and fostered at the tea gardens by the competitive efforts of rival managers, is not overtaking the requirements of the consumer. Another problem before the Ceylon tea planter is, perhaps, even more perplexing than that of preventing a glut in the market. He has yet to discover some method of cultivating the plant or curing the leaf which will give Ceylon tea the enduring qualities of the growths of the Chinese and Assam gardens. It is an open secret in Mining Lane that Ceylon tea will not 'keep.' Your Chinese leaf will stand a year's warehousing; your Cingalese loses its flavour

and fragrance in a quarter of the time. This is a difficulty which ought not to be insuperable to the scientific botanist; and after all, it is one of the points embraced in the larger question as to whether the future prosperity of tea investments does not depend more upon the quality of the product than the quantity produced."—H. and C. Mail.

KINMAN'S No. 251 PATENT TEA DRYER.

TO THE EDITOR OF "THE PLANTERS' GAZETTE."

Sir,—Will you or any of your readers give their experience of Kinman's Drier No. 251, the last one he brought out some three years ago.

Details such as speed of fans, amount turned out per hour, quality of tea,—whether any trouble is experienced with the fine leaf travelling into other parts of the Machine,—whether it has been found suitable for "fine firing;" these and any other details would be very interesting and instructive to one

"SOLEMNLY PUZZLED."

LONDON TEA LETTER.

HONOUR LIST.

Gallebodde (Ceylon) ..	1 Box Golden Tip	£ 2 1 0
Soekamadjoen (Java) ..	6 Boxes Silver Tip	no bid
Hukanpukri (Jokai Assam) ..	12 Boxes Flowery O. P.	4 7
Tjisalak (Java) ..	1 Box Golden Tip	3 0*
Bokel (Jokai), Assam ..	19 Chests B. O. P.	2 2
	Refused.	

From the above it will be seen, that Java has been trying, so far unsuccessfully, to compete with Ceylon in the "Golden Tip" advertisement competition. Very much more meritorious than these fancy samples was the commercial line from Hukanpukri which realised 4s 7d per lb. A sample of this is before me as I write, and it speaks for itself; the liquor is all that could be desired. The coloured "tip" of a rich orange gold, largely predominating over the black "tip." Of course it is practically all "tip," well twisted, and clean, and even in size. Yet, unlike the separately plucked, fancy, Ceylon samples, it has all the appearance of a genuine commercial "Lina."

Of real news there is very little, if any, just now. Everything is quiet, and more or less unsatisfactory in the business world generally, not alone in tea, and there is a wave of depression over things Commercial just now, which is doubtless helping to keep tea down, with other things. It is apparently the usual reaction after a spell of "decent times." The chief anxiety in the Tea Trade here at this moment, is to get at the probable export from India and Ceylon for this season. Accounts vary, and Estimates just now show very wide differences. We are in the week before the August Bank Holiday, and that may account for some of the absence of enquiry, which is so marked a feature of the moment. The question everybody is asking is, "Will India send over her 112 millions, and exceed by so much her last season's export? If she does, and if Ceylon sends as much as is now expected from her, it will be a reverse handi-cup on prices later on, when the heavy arrivals have to be dealt with.

The prospectus of the "Palais Indian Tea Houses, Limited," came to hand too late to refer to by last mail, and is now, of course, old news. The effort is well meant, and should also prove an important insurance for those few public spirited men who have borne the brunt of one fray after another, by subscribing to Guarantee Funds in the interests it is true of themselves, but also of the great majority, who, have, as a rule, been conspicuous by their absence from every effort made to "push" Indian Tea, which involved a pecuniary risk. This new departure may be the beginning, or, more strictly speaking, the second real step in the direction of attracting continental atten-

* It ought to be taken into account that in all these cases fortunes ruined by the collapse of coffee had to be retrieved by tea,—the process being still in operation.—Ed. T. A.

tion to Indian Tea, on a scale which may ultimately compare with the scope and talent displayed by those interested in pushing Ceylon Tea in this country. The weakest part in the Prospectus is the absence of any statistics or data, showing the actual results and rate of improvement in the sales, since the start, at the Paris Exhibition. To those outsiders, if any, who might be tempted to subscribe, this omission might be ominous, as it would, of course be the first thing looked for. I hear that the hairy dust is now being removed from the sorting rooms in some Ceylon Tea Factories by means of small sized Blackman Fans.—*Indian Planter's Gazette*

THE WRECK OF THE QUININE COMBINATION.

In our issue of July 18th we expressed the belief that the last word had not yet been said in the dispute between the Auerbach and the Brunswick quinine factories. Our anticipation proves correct, for we have this week received a communication from Mr. Hugo Andrae, the president of the Auerbach factory, in which he maintains the correctness of the previous statements, and affords us one or two more glimpses into the history of the combination negotiations, which we will chronicle here, not only for the sake of the historical interest which they possess, but also because they may indicate the outlines upon which future attempts at combination building will probably proceed. In the first place, Mr. Andrae explains that, though the figure of 50 marks per kilo. was correctly mentioned by the Brunswick works as the proposed combination-price for sulphate of quinine, that figure was constructed of purely imaginary elements, the figures in the "protocol," embodying the basis of the combination, being only intended to illustrate the proposal of the promoters of the ring. The wording of this part of the "protocol" is as follows:—

§ 7. A certain amount shall be added thereto for cost of production (this amount to be added.)

§ 8. A profit (to be agreed on) to be added to this figure and sum total to form the minimum selling price.

Example:

Price of sulphate in bark, according to paragraph 5	23s per kilo.
Cost of production	15s per kilo.
	38s per kilo.

(Including all charges, freight, &c.):—

Profit agreed upon	12s per kilo.
Minimum selling price	50s ..

The figures, says Mr. Andrae, should be taken in a purely emblematic sense, in proof of which he points out that the amount of 15s per kilo. is so much in excess of what all quinine manufacturers know to be the real cost of production that it could not possibly have been meant to indicate the actual intentions of the would-be combiners.

In our article of July 4th we specially took exception to this estimate of the cost of the production of quinine as an exaggerated one. It further appears from Mr. Andrae's letter that the "protocol" was handed by the Auerbach to the Brunswick representative, not in London, but at Frankfurt-a-M., the seat of another of the four German factories. The selection of Frankfurt as the meeting place of the opposing interests not unnaturally suggests that, on the German side, the Auerbach and Frankfurt factories were the two firms most anxious to bring the negotiations to a successful issue. But the Brunswick directors were obdurate from the outset. At the Frankfurt meeting they declared that no considerations would induce them to sacrifice their freedom of action, and at a subsequent stage of the proceedings they altogether refused to attend the conference, while the London agent of the Brunswick factory selected the very moment when the negotiations approached a critical stage, in the middle of January, to depress the quinine market by offering the drug

right and left at reduced prices. If Mr. Andrae is correct, the position of the Brunswick works was one of antagonism to the planting interests, while the other manufacturers desired, if possible, to include all the planters—and certainly the principal producers in Java and Ceylon—within the projected combination. In his letter to us, Mr. Hugo Andrae claims that all the quinine manufacturers, except the Brunswick works, adopt his side of the question, and agree that it would have been folly to endeavour to establish a combination which left the planters outside—i. e., in opposition.

In other words, Auerbach, according to its apologist, invited the motley multiplicity of interests to seek salvation beneath the ample folds of the grand old combination umbrella, while Brunswick insisted upon figuring as the man who remained true to one party only, and that party was himself. "To leave out the planters," thus argued the majority, "will be to encourage them to form a combination of their own, to establish a quinine factory in the East, and to become their own manufacturers." Such a step has been in contemplation before, and, were the growers to set about its realisation in a determined manner, it is quite possible that the scheme might be worked successfully. But up to the present the planters have shown no more capacity for organisation than the quinine manufacturers themselves.

With regard to the view (set forth by the Brunswick works as the main reason of their withdrawal from the negotiations), that it would be impossible to provide for the absorption of the surplus production of bark by the combination, Mr. Hugo Andrae asserts that the combination promoters hoped to obtain the adhesion of the principal planters to a scheme for the reduction of the output of bark, while they were prepared, if no other way out of the difficulty could be found, to buy up and put aside such a proportion of the stock of bark as would prevent the question of over-supply becoming pressing one for some time. The president of the Auerbach factory believes that the establishment of a union among the planters would have been a difficult, but by no means an impossible, undertaking, and he holds that, if the larger producers could have been got together, the smaller ones might have been safely left alone if they chose to remain outside. But among the manufacturers no outsider could be allowed if the scheme were to succeed.

It is only just to reiterate that the preceding observations are based wholly upon the view taken by the Auerbach factory, and that further communications by other parties to the negotiations might place matters in a somewhat different light. But, at any rate, we cannot affect sorrow at the failure of the quinine interests to form a great organisation which would have absolutely controlled the market and rendered successful competition practically impossible. So far as the revelations we have published enable us to judge, there is now no prospect whatever of the establishment of such an organisation. The combination of the quinine producers appears to be an object more difficult to attain than the union of the Australians, the abolition of standing armies, or the completion of the Channel tunnel, and it is not extravagant to assert that when the latter schemes shall have become facts of ancient history, the quinine people will still be in doubt whether to look east or west for the master mind that shall consolidate them.—*Chemist and Druggist*, July 25th.

A SHORT BRAZILIAN COFFEE CROP.—A Washington Dispatch says that the latest estimate places the Brazilian coffee crop for 1890-91, now coming into market, at 2,200,000 bags. Notwithstanding the high prices the daily receipts do not average over 3,000 bags. Should the present disorganization of labor continue it is believed that the coffee crop for 1891-92, now placed at 8,000,000 or 9,000,000 bags, will not exceed 6,000,000 or 7,000,000 bags.—*Bradstreet's*, August 1st.

NOTES BY "WANDERER."

Aug. 5th.

WEATHER continues damp, so the factories are anything but busy in the high districts, or even over 2,000 ft. Good tea is now being made, and every planter seems determined next year to have plenty of withering room, and facilities where possible, to have the moisture taken off the leaf in cold showery weather. The great desideratum however is to have a sufficient number of coolies to overtake the rush of leaf to the showery weather that follows the dry months of January, February and March. The London *Times* is cabled as having thundered forth the necessity of "England sitting tight to Egypt." The tea planter must "sit tight to Ramasamy," and our Government must be prepared to give assisted passages to our coolies by any route they choose to come to Ceylon.

HEALTH is not very satisfactory among Europeans just now. Colds so severe as to warrant their being called attacks of influenza get hold of the high-countryman, and fever, rheumatism &c. worry the lowcountry planter. We do not hear of the influenza epidemic among coolies as we did last year, but some of the half-starved coolies don't get in touch with their surroundings in Ceylon, till they have a few stomach-aches, and kindred ailments.

PLANTING.—The weather could not have been better for the new clearing and supplying man, if he had got it made to order. A great deal of arrears in supplying has been made up, and little additional to cultivated area of tea have been completed in the older districts. Except on the Uva side of Nuwara Eliya and the lowcountry there has not been any large addition to the area under tea. The Government is quite right in not potting up more land fit for tea cultivation to public sale. We hear of long continued drought in Uva and Udapussellawa. One wonders how the tea bushes will stand these droughts as they get old. Will red spider then get very troublesome, and rust hasten decay? Young coffee could stand drought even in Dumbura, but as it grows old it succumbs. How will a thirsty plant like tea stand 3 months' drought?

THE CEYLON GOVERNMENT RAILWAY is beginning to be a well abused institution. Oh for the days of a Robinson and a Strong!! We hear constantly of badly working brakes, runaway engines and trolleys, discontented servants, and engines not in safe condition. The fact is we want a real administrator for our Chief Manager, whose salary would be sufficient to attract a first-class man from home, to undertake the difficult job of railway administration. The salary given to the Government Agents of the North-Central or Western Provinces would not be too large for a good administrator.

CEYLON TEA COMPANIES.—How to get 15 p.c. on a block capital of opened tea land per acre of £30 will puzzle some of our managers at present prices even with present favorable rates of exchange. Tea cents a lb. is about the profit on an estate yielding 350 lb. an acre on the hills or 35 rupees an acre profit. If tea goes down to eightpence, the company manager will have to scratch his head all the more! However, if Ceylon tea is ever to be cheap, now is the time, for no doubt it is getting into consumption with a vengeance. It is all rot about the non-keeping quality of Ceylon tea except in the month of April, May and June, and we will soon be able to dodge even these months by improvements in withering and firing.

TEA MACHINISTS ARE AWFUL CHARGERS.—The cavalry at Balaclava were not in it with these worthies. The tinker who mended one hole and broke two is no doubt the master of the Ceylon machinist. I believe his future award will be to be put standing in the rain of Pedro for two days, then conveyed in a tea leaf cart to some suitable factory in the neighbourhood of Nuwara Eliya where he will be allowed to wither on a cold damp bed for three days, then to be rolled in Barber's roller for half an hour and Jackson's rapid for another hour. After that he will have two minutes each in the three patent roll breakers. He will then be roasted in the sirocen and Brown's desiccator, and to effect a perfect cure, so

that he may have bowels of compassion on his benefactor, the tea planter, he will then be put in Jackson's cutter and sorted in Walker & Greig's sifter. He will then be sent to Colombo to be sold by auction and there have to listen to the feeble jokes of the tea buyers of our maritime capital. I believe this last process will be the most painful of any of the others described previously.

THE "HEATHEN CHINEE" RIGGING
THE CHINA TEA MARKET.

The Foochow correspondent of the *Hongkong Telegraph*, writing on the 8th, tells the following tale of the alarm there:—We just found out today that much of the excitement was due to shrewd work on the part of some tea speculators. The crop this season opened fairly well and large shipmoots were made to London. Here on account of competition from Amoy, India and Ceylon, the market was very flat and every sale of Foochow entailed heavy loss, running from 20 to 55 per cent and averaging 40 per cent on the lot. This meant ruin to many hongs here and a worse financial condition than has ever prevailed in the history of the place. Some of the people who are heavily interested resorted to an old Wall Street ruse and cabled home that no uprising had begun, rioting was imminent and all the tea-hongs were to be burned to the ground. The *Times*, *Telegraph*, *Standard* and the minor dailies swallowed the bait and published the news as well as editorial paragraphs upon the unexpected trouble. As such a riot as described involved the destruction of the present crop and the cessation of shipments for the rest of the year, the London market revived and prices rose quite handsomely. Those who despatched the telegrams have cleared a good profit and probably recouped their losses. No harm has been done to anybody, but there will undoubtedly be an elephantine roaring and growling when the editors at home discover how they have been imposed upon. As a matter of fact, the Foochow natives are, and have always been docile and peaceable. The only ugly elements are 1,500 discharged Houan soldiers, who are penniless and ready to rob and pilfer at every opportunity. On the other hand there are over 8,000 troops here well-disciplined and armed who could suppress any riot in a half hour. The authorities at Peking are alarmed at the indemnities already demanded from the Yaotze district and have advised the generals here by telegraph and proclamation to prevent the slightest disorder and to behead any one guilty of seditious conduct or even inflammatory language. It is safe to lay 50 to 1 that there will be no serious trouble this season at least.—*N.C. Herald*, Aug. 21st.

COLONIAL [NATAL] TIMBER FOR
RAILWAY PURPOSES.

COMMISSION APPOINTED.

Some interesting papers relative to the testing of the value as timber of certain exotics grown in the colony, such as the eucalyptus, wattle, &c. The QUESTION FIRST AROSE

through the Maritzburg Botanic Society drawing the Government attention to the following points:—

1. To the extreme importance of testing the value as timber of the exotics, such as the eucalyptus, wattle, &c., so freely grown in the colony.

2. To the circumstances that there is, at the present moment, a very large quantity of such exotics of such an age as to be ready for selling.

3. To the fact that, owing to the absence of any such test, there is a prejudice on the part of the users of timber against our exotics; and

4. That the recent arrival of the Conservator of Forests, appears to suggest the present as a suitable time for taking up this question.

According to the Conservator of Forests (Mr. F. Schoepelin) was asked to report, and he recommends the resolution being taken into special consideration, because the question concerning the qualification of some fast-growing exotic species for timber is apparently

URGENT AT THE PRESENT TIME,

and of general interest for the country. The comparatively small amount of timber, which the native forest will be able to yield continuously in future, the natural difficulties of its utilisation on the one hand, the large plantations of exotics on private land, which have passed the stage of a mere experiment, on the other hand, show it as essential part of the work of a forest department, to devote special attention to future plantations on Crown lands. The preceding work of private enterprise facilitates the selection of suitable species of wood. Before entering plantation work on a large scale it will be necessary to certify to the value of the woods by means of a scientific examination of their technical qualities. Species that ought to be examined are *Eucalyptus globulus*, *E. amygdalina*, *E. marginata*, *Pinus insignis*, *Acacia decurrens*. Suitable specimens could be provided from private plantations.

The General Manager of Railways and the Acting Engineer both deprecate immersion, the fact being that unless the creosote is injected into the wood under pressure, it is almost of no value as a preservative. Mr. Shores does not consider that the cost of sending home 500 sleepers and creosoting them will amount to more than £150.

METAL V. IRON SLEEPERS.

Mr. Hunter, in forwarding the correspondences states: I presume those who are interested in the colonial timber trade, and have timber really suitable for the purpose, would not object to cut and furnish Government with say, 500 sleepers for experimental purposes, and in that case the Government might, I think, send home the sleepers to be prepared for trial. As, however, the subject of metal v. timber sleepers is rapidly coming to the front—see my report dated July 14th—it is possible that any expenditure of this kind would be devoid of little value.

COMMISSION APPOINTED.

Dr. Sutherland M.L.C., Capt. G. T. Nicholls, J.P., and Mr. J. W. Shores, M.L.C.E., are in this week's *Gazette* appointed a commission for the purpose of considering and advising the Government on the question of making a fair test of colonial woods for the purpose of railway sleepers.—*Natal Mercury*.

NOTES FROM PEERMAAD.

After two months of persistent rain, we have had a week of fine bright weather, and although, as I write, there are signs of a return of bad weather, the worst of the monsoon is undoubtedly over, and we may now reasonably anticipate a fair percentage of sun for the next month or so, in fact until the advent of the North-East monsoon, which we sincerely hope, will, in this district at any rate, be light, as we have already been blessed with considerably more rain than we require. From statistics received from one of the most central estates in the district, I find that the rainfall in June amounted to inches 50.85; in July, to inches 39.20. In April we had inches 14.60, and in May, inches 24.48, making a total for the year up to the end of July, of 137.30. The heaviest falls of rain occurred on the 20th, 21st and 22nd July, amounting to 12.46.

From the above it will be seen that we had a favourable season for planting, and the young clearings, chiefly tea, are looking well. Nor must I omit mention of the Pepper, of which some 10,000 vines have been planted out on two places on the ghats, and are coming on nicely, as also a small clearing of Liberian coffee. Leaf disease as expected, has made its appearance, and when crops are heaviest the attacks are of course most severe, but with a fine dry September, we shall not, I trust, suffer much; of this, however, I must write later on.

Your correspondent "St. Louis" in his interesting "Planting Notes" gives you such full particulars of the sales of Travancore Tea, that I need allude but slightly to them; I may, however, be pardoned for noticing the good price realised by a parcel of "Bon Ami" Golden Tip, and the fair averages for most of the teas from this district. For the half-year ending June, "Bon Ami" made over 100,000 lb of tea, and will probably make from 150 to 200,000 lb more by the end of the year. The arrival of a new 20 horse power engine will facilitate matters considerably. "Kudawa Kernum," which has also a fine factory and very perfect machinery, among which is a Down-draught Sirocco that gives great satisfaction, probably comes next to "Bon Ami" in output of tea for the past half-year, but I have not particulars at hand sufficient to justify my giving figures. "Glen Mary," mentioned in my last note, has started Steam Machinery, and further additions are shortly expected. Other estates will, doubtless, soon follow suit, and the only fear now is that our roads will be unable to bear the strain of the ever increasing traffic. Our Chief Engineer, I am told, thinks our roads are good enough, and can see nothing wrong in them, probably, if he were a cart owner, or even a shareholder in a tea concern, he would both think and see differently. "Roads in shocking order," "Considerable difficulty in getting cartmen to take away crop," are some of the remarks one hears.

Our popular Dewan, when on a visit here last May, evinced great interest in the Tea enterprise and in planting generally and would undoubtedly see that our interests in the matter of roads are better attended to, if they were brought more prominently and persistently to his notice. The Association should see to this. Another matter, and that a serious one, that requires the attention of the P. A., is the reduction in cost of plucking; the rates now in vogue are too liberal, and can well bear reduction. The prices paid by purchasers of green leaf, on the other hand, have been anything but liberal, and more equitable rates should be fixed. The paddy crops, on the lower slopes of the hills, are not expected to be up to average, this season. Small quantities of the early paddy have already been reaped, but the regular harvest will not be in full swing until the end of next month.—*Madras Times*.

COFFEE CULTURE IN HAWAII.

We are glad to learn of the increased attention paid to coffee planting on Hawaii. Mr. Barnard, of Inopahoe writes that he has 120,000 young trees growing, and we hear that Mr. J. M. Horner, of Kukuian, has thirty acres planted, while Mr. Wm. Horner, of Kukuiahele, has ten acres. All these intend increasing the extent of their plantings as rapidly as they can.

Mr. Rufus A. Layman has purchased a large tract in Puua, located near East Cape, and including the lands of Puua, Kula and Pohohi, with some leased tracts adjoining, which embrace some of the richest coffee lands in that district. There is room for a large plantation there, and we trust the enterprise may prove successful. The want of roads in that district is a drawback and we trust some measures will be taken to secure them. The high price of coffee throughout the world ought to stimulate our planters to push this and any other coffee enterprises, so as to obtain as early returns as possible.—*Planters' Monthly*. [All right, if the leaf fungus is absent and can be excluded.—Ed. T. A.]

CINCHONA IN BENGAL.—The statistics of cinchona cultivation in Bengal for the year 1890-91 have recently been published. During that period the total number of plants, cuttings and seedlings in the Government plantations amounted to 4,749,861 divided as follows; plants in permanent plantation, 4,515,861; stock plants for propagation, 1,600; and seedlings 230,000. The quantity of bark in store at the beginning of the year was 426,256 lb, while the output of bark of the year ending April last was 293,972 lb, making a total of 720,227 lb. From the latter amount has been issued for manufacture of cinchona febrifuge and sulphate of quinine, 250,330 lb, leaving a balance in stock at the end of the year of 469,897 lb.—*M. Mail*.

PRUNING CACAO.

The act of pruning is popularly supposed to cause the production of fruit. That properly carried out, it has this effect, is not to be doubted, but the effect is not so direct as is often assumed.

Given a young tree in good health, and with a single stem, the pruning should commence by the regulation of the *primaries*, or first branches made by the tree. There should, as a general rule, be only three, or at most four primary branches left on the cacao tree. These should be encouraged to extend themselves laterally, as they have a natural tendency to do, and should be encouraged to develop at regular distance the secondary branches. The tertiary branches should also be encouraged to grow at regular intervals.

In these stages the operation should be performed before the wood is sufficiently hard to require the use of the knife, by the method called pinching, which is carried out with the thumb and finger, pinching off the young, succulent shoots that are not required. At all times it should be the endeavour of the pruner to maintain the tree well balanced, *i.e.* it should not have one branch growing more rapidly than another so as to make it appear lopsided from any point of view. Many cultivators do not regard this point sufficiently in carrying out their pruning operations, and many branches are left, owing to their being *bearing branches*, which, for the permanent security of the tree, for its appearance and for its general bearing qualities, should be removed; for it is much better to check at once the tendency of a tree to assume an irregular and un-cultivated form, than to allow a branch to grow for a time and finally be compelled to remove it when of a larger size.

The pruning of a tree should be conducted with a view to the production of fruit. Unless we have a plentiful supply of good healthy leaves, evenly distributed over the tree so as to obtain a maximum of the light and air they require, we cannot expect to secure large crops of fruit, in fact unless the machinery is in good working order and the supply of fuel abundant, we cannot expect a good output. The leaves and roots represent the machinery, and water, sunlight, air and manure, acting together, may well represent the fuel supplied.

The branches of a cacao tree therefore, should be evenly distributed, so that the leaves they carry may be maintained in good health, and just thinly enough distributed to admit sufficient sun and air to mature the fruit.

In pruning neglected trees, the first thing to do, is to cut out all useless wood, or wood which can never be expected to bear, or to produce bearing branches. Next, to equalize or balance your tree, and last to thin out your branches, and fore-shorten them when required.

In removing branches the greatest care should be exercised not to make jagged, ragged, splintering or slivering cuts, but to make clean and even cuts close to the wood and near to a bud or young branch into which the sap will be presently directed if the operation is well performed.

The young branches which are often found growing erect, (commonly called gormandizers from the rapidity of their growth), are productions which show that the parent stem, as it stands, does not provide sufficient channels for the expenditure of the sap supplied by the roots, and in consequence this sap provides for itself an outlet and expends itself upon the production of rapid growth in a single direction. It shows that the channels for the conveyance of sap are clogged or contracted, and that the amount of sap produced cannot pass into the more matured portion of the tree. It is also an effort of nature to recover itself from hard work. Every physiologist knows that unless branches are produced, roots cannot be, and the production of root is in exact ratio to the production of branch. When however a tree is bearing fairly in proportion to its size, it is better to keep down these branches, removing them as soon as they appear, as it is certain that by affording free openings for the absorption of the sap, they rob the

crop of the full amount of nourishment it should obtain, and the productive powers of the tree is seriously affected. They should be removed however as they appear, and not be allowed to grow to a large size and then be removed, as that practice would be simply a waste of all the material used up in producing them, instead of diverting it to the production of fruit. In cases where a cacao tree has evidently become somewhat worn out or barren, (*i.e.*) its bearing wood shows evident signs of an unhealthy condition, it is better to make use of a "gormandizer" to supply a new bearing head to the tree and give it a new lease of life.

By allowing one of these branches to grow from a suitable portion on the stem and treating it carefully in a similar manner as we would a young plant, it is possible to rejuvenate and bring again into bearing trees from which, owing to their stunted and contracted character no produce could ever be expected. And it is really wonderful in what a short time the operation can be completed if skilfully carried out. After the young tree thus formed has assumed fair proportions the older wood should be carefully cut away from time, to time, but not at once, as heavy pruning is always a check to growth. If pruning is done by a saw the wounds should afterwards be smoothed over with a sharp knife as they always heal over better if thus treated. In situations where the cacao beetle or beetles (for there are several species), are plentiful a mixture of coal tar and clay of the consistency of paint should be applied to all wounds.

Pruning with a blunt cutlass, knife, or cacao hook, should never be allowed. The instruments used should be those only which are able to carry a keen edge, and pruners should always be supplied with the means of sharpening them without leaving the field.

The time for pruning is much insisted upon in Trinidad as being influenced by the "moon." On this point I desire to remain passive, in a similar way as the big blacksmith did when he allowed his little wife to boat him. As the tale goes—when asked why he allowed it, "Why," said he, "it pleases her and it don't hurt me, so what matters?" Well if it pleases the cacao planters to prune at a particular time of the moon, by all means let them do so. It pleases them, and it does not hurt the trees, so it cannot matter. Mr. Morris, when writing on the same point, used the following words:—

"The Spaniards have a deeply-rooted prejudice against trimming cacao at full moon. They say it causes the tree to bleed and eventually to die. It is a well known and general axiom in horticulture that trees should not be pruned when sap is most active, but with regard to the particular instance of the cacao tree it is a question which only experience and intelligent cacao planters can determine. I was myself led to look upon the prejudice, at first, as having some general grounds based upon long acquaintance with the habits of the cacao tree, but when I found Spanish settlers had equally strong prejudices against gathering pods for seed purposes, and putting out plants during the same period, I came to the conclusion that the subject was one which might very fairly be left for the present an open question. I may add that I saw in Trinidad, trees pruned on good estates at all phases of the moon, and no injurious effects had been noticed or anticipated."

Whether the moon has an influence on plant growth or not, I am in accord with Mr. Morris that the matter had better be left an open question; not that I have any personal doubt upon the matter, but the question being one in which my opinion has little or no influence either way upon the progress of cultivation; each individual may adhere to his own particular practice without being at a disadvantage. Through a succession of nearly thirty years' practical experience, I have personally carried out a number of experiments bearing on the subject, in the course of which I could not find that the moon's influence on plant life was other than completely *nil*.

The season for pruning is however a different matter, but on this also opinions differ. It is how-

ever generally taken as an accepted rule that in established cacao, pruning or "trimming" as it is called in Trinidad, is best carried on at the close of crop time." The practice is certainly reasonable as the trees are devoid of both fruit and flowers and suffer no possibility of injury.

On first class estates where cultivation is carried out in a scientific manner, the tree should annually receive attention in the matter of pruning &c. Every tree should be visited and carefully examined. On many estates in Trinidad it is the practice to prune only at intervals of once in three or four years. Such cannot be considered good practice as the less pruning that is done to a tree at one operation the better.

It should be remembered that a cut made in pruning a tree, is just as much a wound, as cutting of a finger from the human body, and that although the plant may repair the injury to a certain extent still the wound remains, and produces a certain disorganization of tissue, not seldom resulting in decay and death.

The cultivator should be careful in removing and burning as far as possible prunings from the ground. If left to rot upon the plantation these prunings become the home of innumerable wood destroying insects, and beetles which are inimicable to the welfare of the cacao plant. There is nothing like tidiness and cleanliness in any cultivation, and departure therefrom is sure to produce sooner or later its concomitant evils.

The practice of pruning, the way to hold knife or saw, cutlass or cacao hook, cannot be taught by any writer. The inexperienced should seek practical instruction, and even then it requires a considerable amount of time and experience ere he will be able to handle his tools, with dexterity and precision.

The difference between a slovenly and a clean cut are at once apparent when the work is compared, and no workman should be permitted to practice pruning upon valuable trees until he is well accomplished in the practical use of the tools employed.

The skilful pruner can, by a proper handling of his tools, and cutting back to buds situated in the positions from which he desires a branch to come, from the tree at will into the shape he requires, and the plantations in which his skill is exhibited will always present a tidy and cultivated appearance, while those of the negligent and unskilful pruner will always look untidy and irregular.

Good maxims for the cultivator are, "prune little, but prune often; prune carefully, but prune with decision. Prune for leaves and a crop must come."

—*Trinidad Agricultural Record.*

RECOVERY OF VINES FROM PHYLLOXERA.—By the latest inspection of the Phylloxera-infested districts of Portugal by the officials of the Portuguese Agricultural Institute, some interesting observations were made, says Dr. Klein in the *Gardens' Chronicle* for May. Vines which had been infested for a number of years, and dressed latterly with sulphate of copper, had completely recovered from the attack, and given extraordinary crops, a fact which is not without analogy in the history of the malady. It is the question now, if the proprietors can bear the cost entailed by a continuance of the expensive remedy. In other cases it would appear, that where rows of trees intersected the vineyards, the trees were attacked by the Phylloxera—which the Editor questions. These trees acted as traps or conductors for the lice; and so far no evil consequences to the trees have appeared.—*Gardens' Chronicle.*

THE BREAD FRUIT TREE is a native of the islands of the Pacific Ocean and the Indian Archipelago, and grows to a height of from forty to fifty feet. It has large, pinnatifid leaves, frequently twelve to eighteen inches long, dark green and glossy. The fruit of the bread-tree, which in shape and size resembles a muskmelon, supplies the principal part of the food of the inhabitants of those islands. It is attached to the small branches of the tree by a small, thick stalk, and hangs either singly or in clusters of two or three together. It contains a somewhat fibrous pulp, which,

when ripe, becomes juicy and yellow, but has then a rotten taste. At an earlier stage, when it is gathered for use, the pulp is white and mealy and of a consistence resembling new bread. The common method of preparing this fruit for eating is to cut it into three or four pieces, and then take out the core, then to place heated stones in the bottom of a hole dug in the ground, to cover them with green leaves, and upon these to place a layer of the fruit, then stones leaves and fruit alternately, till the hole is nearly filled, when leaves and earth to the depth of several inches are spread over all. In rather more than half-an-hour the bread-fruit is ready for eating. It has little taste, and more resembles the plantain than bread made of wheat flour. The inner bark of the bread-fruit trees supplies a considerable part of the clothing of the islanders, and its milky juice are employed for economical purposes.—*American Grocer.* [In Ceylon the fruit is cooked as a vegetable, and it is very good in curries.—*Ed. T. A.*]

TEA IN INDIA.—A rather pessimist "Britisher" writes to the *Indian Planter's Gazette*.—

The present state of the Tea Industry for India is doomed except for very fertile lands, with enormous yields as in the Dooras; the competition with Ceylon has brought this about, owing to the latter island's superior natural advantages, a forcing climate and soil which gives an enormous yield. Planters wish that Government therefore would remove the hampering restrictions on the industry, and grant them laws by which they might be able to fight this great battle of competition. Not one of the Darjeeling gardens last year earned a *kworie* of rent; according to the *law of rent* as laid down, as one of the first doctrines of political economy by Ricardo and Malthus, Darjeeling lands are held either freehold or else leasehold at the rate of 6 (six) annas per acre, and it is chiefly due to this fact that the gardens are striving on, so as not to lose the whole capital sunk in tea.

Not a banker in India will advance money to open up tea estates on the security of Tea alone, showing that they consider the industry doomed and will never pay the interest, whereas in Ceylon money is easily found.

Last year, 1890, only two gardens earned a banker's interest, that is 8 to 10 per cent.; two gardens earned a dividend larger than Government Paper interest, viz, between 4 and 8 per cent. interest; four gardens earned a dividend of 2 per cent.; and fully 60 per cent. of the land under Tea, in the remaining gardens, made no dividend but a loss, not one earned any rent.

EGG PLANTS.—A recent *Bulletin* of the Agricultural Experiment Station of Cornell University, deals with the varieties, cultivation, and mode of cooking of the fruits of Egg plants, including the Aubergines. Professor Bailey says the requisites for success are "early starting, warm quarters, vigorous plants, rather late transplanting, warm, rich, moist soil, and constant attention against insect pests." The best varieties are Early Dwarf Purple, Early Long Purple, White Chinese, and black Peking as a late variety. The best market varieties are New York Improved and black Peking, with Early long Purple for the first demands. The methods of cooking are as follow:—

"1. *Fried.*—Cut in slices crosswise not over a half-inch thick, and parboil in salt water about fifteen minutes; then remove, and fry in a hot "spider" in butter and lard.

"2. *Fried.*—Cut into slices $\frac{1}{4}$ or $\frac{1}{2}$ inch thick, and lay in strong brine for two hours; then wash very thoroughly; sprinkle with brown sugar, pepper and salt, and fry slowly to a dark brown.

"3. *Baked.*—Cut in two lengthwise, remove the seeds and pulp, and fill with dressing made of half a teaspoonful bread crumbs, one teaspoonful butter, and salt and pepper to taste; lay the halves side to side in dripping pan, add a little water, and bake nearly an hour.

"4. *Frutters.*—Pare, cut in thin slices crosswise, and soak in salt water for eight or ten hours; dry on a towel, dip in beaten egg and roll in bread crumbs, then fry slowly in hot butter until the pieces become a rich brown; serve hot."—*Gardens' Chronicle.*

* "Cacao," by Mr. Morris, p. 29.

THE ARTIFICIAL PROPAGATION OF PEARL BEARING SHELLS AND THE PRODUCTION OF PEARLS BY ARTIFICIAL MEANS.

All the efforts as yet made in Ceylon and Southern India to propagate artificially the pearl oysters have been failures, chiefly, we believe, because the experiments were carried on in waters too shallow for the healthy life of the bivalves. We feel much confidence that success will yet be attained, and we certainly shall not despair until a fair trial is given to coir cables, or strong, coarse, wide meshed coir nets anchored over the pearl bank region, so as to float a couple of fathoms or so below the surface of the sea. We are not aware that any experiments have been tried in the direction of inducing our "oysters" to produce artificial pearls by irritation of the animal, or by the introduction of foreign bodies to become the nuclei of layers of nacre. In Australia a large measure of success seems to have attended experiments for the propagation of shells (mainly we suppose the great mother-o'-pearl yielders) and the artificial production of pearls. Our latest news on the subject is contained in the following telegram in the *Argus*:—

"Thursday Island, Aug. 21.—Experiments initiated by the commissioner of fisheries, Mr. Saville Kent, two years ago in the direction of causing mother of pearl shells to produce pearls by artificial treatment proved substantially successful and encourages the expectation of important developments in connection with the cultivation of pearl shell, which are now proved perfectly feasible. The shells in the experimental nursery at Vuren Point are progressing well and propagating."

Capt. Donnan will, of course, "take a note on." In the South Sea Islands, corals have been successfully propagated by cuttings!

SOIL ANALYSES AND THE VALUE AND VALUATIONS OF MANURES.

Although the elaborate letter by Mr. Pringle which we publish below was written primarily with reference to coffee in South Coorg, the general principles propounded apply as much to tea soil and tea as to coffee soils and coffee. In the olden days when coffee was King of Ceylon products, and before leaf disease appeared to produce "insidious defunction," many of us, in our attention to crop, were apt to forget the value of leaves to both bush and crop and also the demands they made on tree and soil. *Hemiteia vastatrix* taught us a striking lesson in vegetable physiology, by the process of weakening and finally killing the coffee bushes from exhaustion, in their desperate efforts to produce crops of leaves, which scarcely appeared when their life juices were absorbed by the parasite. It is the prevalent theory, and it is true, that our climate specially favours the production of leaf; the rapidly increasing tea crops conclusively prove that this is the case. But it does not follow that exhaustion and even death may not ultimately be the result of the processes of constant leaf-plucking and branch and twig pruning, unless the elements thus abstracted are restored to the soil and that in the best possible form. If moderate manuring could be afforded, it would be useful in the early years of an estate; but as the plantation advances in age, the recuperative and yielding powers of the bushes must on every principle of agricultural chemistry, diminish, unless the deficiencies of fertilizing

substances in the soil are supplied. Analyses of the soils will then be useful as revealing the element or elements chiefly needed; but, happily, even if this information cannot be obtained, a planter cannot go wrong in applying cattle shed manure and all "dirt in the wrong place" to his fields. If none, or only a limited quantity of natural manure is available, then an artificial application in the shape of good bones and a castor cake is as valuable for tea as it ever was for coffee. Fish and other specially ammoniacal substances are also valuable, but our chief dependence must be on bones and "poonac," what Mr. Pringle calls "hindy." The quality of each, however, varies considerably, and although the good faith of the leading dealers in the two articles named can be, as a rule depended on, yet it is well that analyses should be resorted to, especially where large quantities may be ordered. It will be seen that Mr. Pringle deems an application of iron sulphate advantageous to some soils. In most of our Ceylon soils, there is, naturally, a proportion of iron which (and we may say the same of clay) render them far better calculated for the growth of tea than for coffee. Our climate is, on the whole, one of the best tea climates in the world. Rather too much wet is, doubtless in some districts, an obstacle to the withering process in the case of gathered flush, but science founded on experience is rapidly providing remedies.

The facts and figures adduced and the principles enforced by Mr. Pringle cannot fail, we submit, to be of value to the tea planters of Ceylon, when deciding on the manures to apply and the mode of applying them. We fear that on but few of our estates could the "broadcast" process be carried out, although it is doubtless the best in theory. But that is a matter of detail. The great lesson to be learned and practically applied is, that the luxuriance of the growth of the tea plant in Ceylon and the unexpectedly large and increasing yield of leaf per acre are the strongest possible arguments against evading the duty of restoring, as far as we can, to the soil whence our crops come, the elements of which we are constantly depriving it.

THE VALUE AND VALUATION OF MANURES: PART I.

By WILLIAM PRINGLE, M. S. C. I.,

LATE AGRICULTURAL CHEMIST TO MESSRS. MATHESON & CO. IN COORG.

(Under special arrangement for publication in the "Ceylon Observer" and "Tropical Agriculturist.")

Every planter and agriculturist accepts the dictum that manures are valuable aids to the cultivation of crops; sometimes their value is questioned, but this generally happens when the manure used has proved unsuitable to the land or to the crop, or there may not have been enough applied, or there may have been too much.

Coffee supplies will stand 4 cwt. per acre of Ammonia Sulphate under favourable conditions of weather, but 8 cwt. is too much, it kills them off. Under like conditions 5 tons of cattle manure (first quality) answered well, but 10 tons was almost as bad as 8 cwt. of Ammonia Sulphate. This shows that even cattle manure must be used with discretion. It is deservedly a favourite; it's like a charge of snipe shot, it covers a wide area, and has less chance of missing the mark than such a manure as hindy, i. e. oil cake; in which the ammonia preponderates so greatly over the other manurial elements; this sometimes like a bullet misses its billet.

Theoretically a very poor soil has sufficient materials for a great number of crops, practically it has not; hence the value of manures.

There is a general law of the greatest practical importance to all agriculturists and planters, viz: "That if a soil be deficient in ANY ONE ELEMENT, no manure is of value on that land that does not supply the deficiency. For instance in England practice has shown phosphoric acid to be the element required by turnips, and as a rule phosphatic manures produce good results; but if the soil is short of nitrogen or potash, manures supplying only phosphates will be of little or no value. Again if the soil be short of iron or sulphuric acid, wonderful results may be got by the application of iron sulphate in moderate doses; but if there happens to be a large quantity of ferrous salts already in the land the results are nil or worse, the crop may be killed off. Gypsum, *i. e.* Sulphate of Lime, is often very useful where lime and sulphuric acid are required, as it supplies them cheaply especially, when a super phosphate is used, as only the soluble phosphates are paid for.

Every agriculturist is familiar with the fact that repeated applications of lime exhaust the land unless they are well backed up by manure. This results from the circumstance that lime renders the nitrogenous matter of the soil more easily assimilable by the plant, the ammonia acts as a powerful stimulant and the increased energy of the plant enables it to absorb such food as the roots come in contact with more rapidly. The soil is exhausted when any one of the elements of fertility is reduced in quantity below that necessary to supply the immediate requirements of the plant in an easily assimilable form. There may be plenty of the element in the soil, but so shut up by its combination with silica &c. that it is not immediately available as plant food; the value of comparative soil analyses which enable us to judge what is necessary to supply the deficiency of the soil is of primary importance, as we are by them able to render the necessary assistance to the soil, that is supply a manure that will remedy the defect. To quote Sibson and Dr. Voelcker:—"The infertility of a soil is often explained by an analysis; the soil may be suffering from the want of some material indispensable to the growth of plants, or it may contain something poisonous to plants; in either case chemistry is generally able to enlighten us and to point out means of remedying the evil. Of a soil whose fertility is impaired we can all pronounce that it wants manuring; but with the assistance of an analysis we may also learn in what substance the soil is deficient or what kind of manure it wants. With this knowledge we may restore its fertility in the most economical manner." As pointed out in my paper on coffee manures, soil analyses settle many vexed questions of cultivation; they decide the question as to whether the land requires drainage; whether shade should be thick or thin, but the greatest value to the planter lies in the fact that they enable him to get full manurial value for his money. Having settled what the soil requires we must next enquire what the plant demands. Unfortunately there is no royal road to this end. Experiments on soils of known composition with widely varying conditions, of climate, soil, &c. are needed to finally settle the question. The cereals and root crops of Britain have been and are the subjects of constant study and experiment.

Lawes and Gilbert's work has done much to solve many abstruse questions and to place the cultivation of cereals and root crops in England on a scientific basis, enabling her to compete with the prairie lands of America, Australia and the cheap labour of India in the growth of wheat and other crops. Such experiments are much needed in connection with Tropical Produce. It was the want of such experiments in regard to coffee, tea, cocoa, &c. that led me in my paper on coffee manures to say that "The question of manuring coffee has had little systematic work spent on it, compared with the vast interests at stake." Had I said "little systematic experimental work," most people would have agreed with me. I was fully aware of the valuable work done by Messrs. Marshall Ward, Morris, Thwaites, Trimen and others in connection with *Hemelia vastatrix*. The thorough

systematic investigation of that pest is deserving of the highest praise: I consider that the thanks of the whole coffee planting community are due to the before named gentlemen, the Ceylon Planters, Government, and *Observer* newspaper for the energy and zeal displayed in their crusade against the pest; the information gained is of inestimable value in guiding future investigations.

Highly analyses I know and fully appreciate the value of, but I would like to see systematic experiments put in hand to determine what is to use Ville's words the "dominant element" required in a manure for coffee, tea, cocoa, and other tropical products. Having found the dominant element we must first supply the deficiency—(if any exist), and the probability that it does is great) in the soil, then apply it. From the view of a plant, few soils are complete; a complete soil should grow any and every plant equally well provided the climate is equally suitable; it's only a question of £ s. d. With suitable manures you can grow plants in calcined sand. Coffee Aralia can be made to yield a ton per acre; on small blocks say up to 5 acres or so, it pays to spend £200 to £300 per acre per annum and pick crops of 10 cwt. to a ton. But when we come to 200 to 1,000 acres or more, the labour difficulties are so great that such cultivation is a practical impossibility. An average of 5 cwt. per acre must for coffee under shade with ordinary work and manure be considered good. Except on very poor land, and patches of such exist on every estate, such crops can be got in South Coorg.

The crop of one block of estates there has averaged 4 cwt. per acre per annum for the last ten years, and there are other blocks as good; individual estates with much higher averages are to be seen throughout the district.

There is every prospect of the average being raised, as the labour difficulties are overcome and the general work can be kept well in hand, allowing of steady systematic annual broadest manuring being carried out at the right time. There is little doubt that it is best to manure every portion of the estate yearly, but under some circumstances if the labour is sufficient, two manurings would be better for the trees. Last year (1890) South Coorg was no better off for labour than her neighbours; the evil effects were pointed out, and the district bestirred itself and procured coolies to replace the Cauarese. Tamil labour was introduced; coolies were not paid off at the usual time, but were retained as long as possible. All the supply pits required for perceptible vacancies were cut in the hot weather, the weeds were kept down, and I had the pleasure of seeing supplying briskly proceeding early in June.

Leaf disease (in Coorg) in the hot weather receives a severe check and I do not think that where the land is well and deeply cultivated and efficiently manured that there is much fear of it on well drained land killing off the trees; but there is no denying that it does often seriously affect crops. A tree cannot exert its energies to produce leaves when bearing crops, without dropping some of it. Efficient manures adapted to the necessity of the plant and the deficiencies of the soil are of the greatest assistance.

Too much stress as regards manures for coffee has been laid on the composition of the henn, and too little attention devoted to the leaves and prunings. Take Marshall Ward's figures, twenty-one weeks as the duration of the life of a coffee leaf, the tree must shed all its leaves 2½ times in a year; under shade they remain a little longer, but the trees as a rule certainly renew their leaves at least twice a year. This loss on a healthy tree is not noticed as it proceeds all the year round. It is a poor tree of seven years growth that has not at some period of the year at least fifteen hundred leaves, a fair average tree will have over two thousand, and a first class one in full leaf as many as three thousand or more. Then there are the prunings.

Let practical planters experiment as Mr. Cameron F.R.S. of the Botanical Gardens, Bangalore, suggested to me the other day: surrounding a tree with wire netting, collecting the leaves and prunings weekly or monthly, dry and weigh them, and have them analysed.

With other produce the same course should be pursued. In this way it would be seen what demand the plaut makes on the soil for available food at different periods of the year.

Having decided that a manure is required and what it is to be, the question is how to supply the estate with it at the least cost in the most suitable form. All manures vary greatly in quality; a merchant guarantees the bones or other manure supplied as pure, but the quality of pure bones and other manures of undoubted purity are of very different manerial value. The following analyses show how widely pure bones vary in quality:—

Analyst.	Macadam.		Sibson.	
	Highest.	Lowest.	Highest.	Lowest.
	per cent	per cent	per cent	per cent
Phosphates	57.08	44.72	48.14	44.95
Ammonia	5.23	3.34	—	—
Alkaline Salts	.85	.32	1.91	.63

Analyst.	Hughes.		Pringle.	
	Highest.	Lowest.	Highest.	Lowest.
	per cent	per cent	per cent	per cent
Phosphates	54.03	39.40	52.25	43.77
Ammonia	4.43	3.01	5.09	3.25
Alkaline Salts	—	—	2.03	.50

Sibson unfortunately does not give the ammonia, and Hughes unfortunately does give the carbonic acid with the alkaline salts which prevents comparison, but on page 107 of his report on "Ceylon coffee soils and manures" the composition of Indian bone dust is assumed to be

	per cent.		
Nitrogen	3.5	Equal to Ammonia	4.25
Phosphoric acid	24	" "	Phosphates 52.32
Potash	1	" "	

Here then in pure bones or what is sold as such we have Phosphates (*i. e.* Tricalcic phosphate) varying from 39.40 per cent up to 57.08 per cent and the Ammonia from 3.01 per cent up to 5.23 per cent.

The alkaline salts found in bones are generally assumed to be magoesia and soda, but in some samples a notable quantity of potash is found, whether it is derived from the food of the animal or from accidental mixture with ashes I am not able to say. The Agricultural Societies of Britain generally fix selling price units for the season and manures are valued on them; for Southern India and Ceylon the units might be fixed by the Planting Associations and the Chambers of Commerce.

For the present I will take bones and oil cake as the standards for phosphates and nitrogen. It is necessary in the first place to decide what constitutes a fair marketable quality of bones and Hindy *i. e.* oilcake.

In England the manure manufacturers generally buy bones on a basis of 48 per cent phosphates (*i. e.* Tricalcic phosphate) and 4 per cent ammonia. Numerous analyses show this to be a fair average.

For valuing bones the alkaline salts are not considered, only the phosphates and ammonia being paid for. Assuming the price per ton for bone flour of that quality to be R60 in Bangalore, Colombo and the west coast, we can estimate the value of other manures in comparison with it. Castor hindy may safely be assumed to contain 6 per cent of ammonia and costs say R36 per ton; the ash though very valuable as plant food is not valued, as it generally corresponds to the per cent of ammonia. We thus get the value of six ton units of ammonia in oil cake at Thirty-six rupees or rupees six per unit per ton; that in raw bone flour is worth as much per unit. Deducting the value of four units of ammonia R24 from the total price of the flour we get R36 as the value of 48 units of phosphates or three-fourths of a rupee per unit per ton for phosphates. The Home price is about one shilling and ninepence for phosphates and eleven to twelve shillings for ammonia. So that these manures here are cheaper than in England. As showing the valuable nature of castor

oak and of its ash the following analyses may be of interest:—

	Castor oak parts per 100.	
Moisture	6.71
Oil	10.03
Albuminous Compound	30.29
Mucilage gum &c.	19.64
Woody Fibre...	27.34
Soluble Ash...	5.16
Insoluble matter, sand, &c.83
		<hr/> 100.00
Containing Nitrogen	5.05
Equal to ammonia	6.13
Soluble Ash Analyses		
Lime09
Magoesia67
Potash	1.68
Soda76
Phosphoric Acid	1.21
Sulphuric Acid24
Chlorine...21
		<hr/> 5.16

Analyses of the ash of oil cakes are seldom made, but the proportion of phosphoric acid worked out to phosphates is equal to 2.64 per cent, worth very nearly R2 per ton, and there is potash 1.93, worth about another two rupees. But the R6 paid for each unit of ammonia covers that.

The following are the generally accepted proportionate values of phosphates and ammonia.

Phosphates, Ammonia.			
90 per cent pass through screen			
Bones	½ inch mesh	20	132
Meal 1/6	" "	21	138
Flour 1/80	" "	22	144
Fish whole (about the size of sprats)		21	144
Meal 1/16		22	150
Oil cake 1/16		—	144

In England the price of ammonia chiefly depends on the supply of ammonia sulphate, in India most probably on oil cake; a determination of the nitrogen in it, expressed as ammonia is all that is required to determine its value, as the consumer knows that from a manerial point of view, if the cake is rich in nitrogen the percentage of, to him, valuable ash will be high, and the valueless oil low, and vice versa.

Carriage is a most important item to most plantors, and an oil cake which has over six per cent of ammonia is more valuable proportionately to them on this account than one with less, though both are paid for at the same rate per unit ton. The buying of oil cake by analyses is the fairest plan both for plantors and manufacturers. For instance suppose two coast firms offer oil cake one at R36 with 6 per cent ammonia and one at R42 per ton with 7 per cent delivered on the coast. The upcountry planter has we will say R10 per ton to pay for carriage, therefore the prices of the cakes on his estate are respectively R46 for 6 per cent, or R7 and 66 cents or R7, 10 annas and 8 pices, while the 7 per cent costs R52 per ton or R7 and 43 cents or R7 6 annas 10 pices. Let us suppose the order to be for 100 tons 6 per cent or the equivalent in 7 per cent, then the bill stands as follows:—

100 tons 6 per cent at R36	R3,600
Carriage at R10	1,000
Cost on the estate	<hr/> R4,600
Ammonia supplied 6 tons cost per ton	R766
Only 85 tons 14 cwt. 1 qr. of 7 per cent are required to supply 6 tons Ammonia therefore the cost is roughly 85 tons 14 cwt. 1 qr. at R42	R3,600
Carriage on the above at R10	857
	<hr/> R4,457
6 tons Ammonia supplied cost per ton	R743

The actual saving by purchasing the equivalent of 7 per cent. instead of 100 tons of 6 per cent. R143, a saving not to be despised in these hard times. The most careful and conscientious maker of oil cakes can only guarantee that they shall contain a certain per cent. of ammonia, if he supplies more it is only right that he should be paid for it, or he can divide his cakes into classes to suit his customers. On the other hand the consumer has an equal right to ask for the cake he likes best, and is prepared to pay for.

In some cases where carriage is difficult it would pay the planter to give a rupee or even two per unit ton more for a high class oil cake with 9 to 10 per cent. Ammonia. White castor cake of this quality can be produced, though Macadam gives the average for castor cake in great Britain as 5 1/2 per cent. Hughes gives 9.45 per cent. as the highest for white castor, but the sample had 11.57 per cent oil in it which could with advantage to the planters be reduced to 5 per cent. or less.

WILLIAM PRINGLE, M.S.C.I.

Bangalore, Aug. 24th, 1891.

TEA, COFFEE AND CACAO.

In articles which we extract from the *Home and Colonial Mail*, the *Grocer*, and the *Financial News*, there is much interesting discussion regarding the three products named above. The decline of coffee consumption in Britain has no special connection with the decadence of coffee crops in Ceylon. The article is clearer (calculating by bulk of infusion), more difficult to prepare, and far more liable to adulteration, than tea. We are not so sure, however, that the *Financial News* is correct in tracing no connection between the increase of specially high quality cacao from Ceylon and the largely increased use of this fatty and nourishing article, Linnaeus's "food of the gods," in Britain. The British householder who is choise in his taste and able to gratify it knows a good article when he sees it. And that Ceylon cacao is, beyond all question, the best in the world,—due largely to extreme care and the application of scientific principles in its preparation, we believe,—is evident from the comparative prices in the British market in 1890. We give the ascending scale:—

Grenada	...	59/ to 63/ per cwt.
Trinidad	...	68/ to 70/ "
Guayaquil (Arriba)	...	90/ to 97/6 "
CEYLON	...	119/ to 125/ "

the latter rising at one time during the year to 133/ per cwt. With such prices and advancing consumption, surely the few who are growing cacao successfully are to be congratulated. For growers of tea, too, who dread a repetition of that over-production which rendered the cinchona enterprise unremunerative, there is comfort in the articles we quote. Tea is not only easier made and cheaper than coffee, but our Ceylon product, equally with the Indian, gives a greatly increased number of cups per lb. more than is yielded by China tea. Ceylon tea, with all the attacks on it by foes and the pessimism of friends, is beyond question, the favourite tea in the market, and is likely to benefit specially by all advances in consumption of "the cups that cheer but not inebriate" in Britain and in "new markets." In the great leading market of the world, it will be seen, the consumption of tea, under the influence of reductions in duty and cost price, has increased in four decades thus:—

	lb.
In 1860 consumption was only	77,000,000
In 1870 the quantity rose to	...112,000,000
In 1880 there was an advance to	...160,000,000
While in 1890 there was a sudden spring to	...194,000,000

Much of the advance is traced to the reduction of duty, and there can be little doubt that the end of 1891 will see the round 200,000,000 lb. exceeded, with an advance up to the three hundred millions of lb. by the end of the decade and the century. Such a result in Britain, where the consumption of tea has now reached 5 lb. a head,—equivalent to at least 7 lb., considering the greater strength of Indian and Ceylon tea—and proportionate advances in other markets, depend, of course on the preservation of peace, for which we have material as well as moral reasons to pray. Preparations for war have, in truth, become so awful in their immensity and their destructive character, that while on the one hand there is danger of an outbreak being precipitated, there is on the other the dread which even the most unscrupulous must feel at letting loose forces so far-reaching and calculated so rapidly to decide, not only the fortunes of campaigns, but the destinies of nations.

NOTES ON PRODUCE AND FINANCE.

INDIAN TEA IN PARIS.—If Indian tea is to make its way in Paris funds are necessary for the purpose. That a coffee drinking nation can be induced at all once to change its taste is not at all likely, but there is a very good prospect indeed that the consumption of tea will steadily increase if the sale is persistently pushed. The question is, Shall the enterprisers languish for want of money?

THE POSITION OF TEA AND TEA COMPANIES.—The article in the *Financial News* on this subject, which we quoted last week, has called forth some correspondence in the paper. "J. C." writes:—"As you doubtless wish that all your information should be as accurate as possible, perhaps you will allow me to point out that in quoting tea shares for 1890 some allowance should be made, to the extent of say, two per cent. for the advance in the value of the rupee. With regard to Ceylon companies, I may mention that while the Ceylon Tea Plantation Company has paid 15 per cent. for five successive years, other Ceylon companies have paid 20 per cent and 30 per cent. It is quite correct to say that Ceylon tea has the bad reputation of not keeping; but I think you will find, on enquiry 'in the Lane,' that this refers only to parcels made during unfavourable weather. I saw some broken Pekoo a week ago sampled against some of last year's crop from the same estate, which was decidedly inferior to the old leaf of 1890. I am not one of those who believe in the enormous estimates for future Ceylon crops of tea, but the quality be only fairly maintained, I am confident that the new markets opening up in Russia and the United States will absorb all the leaf which Ceylon can produce. Allow me to assure you that I am not interested in Ceylon tea or tea estates." "Wiry Leaf" writes:—"I am glad you have again brought these investments under the notice of the public, for really such concerns seem to be about the only ones that would not be injured or ruined by strikes, as in the case of rails, trams, steamships, docks, &c. Indeed, tea and milk, and perhaps ginger-beer, will be the only things left to drink soon. Coffee is not in favour, and is 90 per cent. chievery, and cocoa is similarly adulterated. Some months ago you inserted one or two letters from me under my present *nom de plume*, in which I called attention to different tea companies, especially British Indian and Eastern Assam. The former, at the close of the season, July, 1890, was £1,600 to the bad; but now—July, 1891—not only is this wiped off, but about £2,000 paid in dividends, and £100 carried forward. The Eastern Assam in 1886 was £10,000 to the bad, but has made a profit each year since, and there is every reason to anticipate that not only will the small remaining balance be wiped off this year, but a dividend is not impossible.

LAST WEEK'S TEA SALE.—The quantity, says the *Produce Markets' Review*, of Indian tea brought forward has been larger than last week, the proportion of the lower descriptions giving a poor infusion being consider-

able, but nevertheless prices for these kinds have remained steady. Good new season's teas have been in active demand and have realised firm to advanced rates, while a few parcels of Darjeeling growth of unusually good quality have fetched higher prices than the trade have been accustomed to pay for some time past, the average for one invoice of about 60 packages being over 2s. 2 1/2 p. lb. At the public sales about 18,200 packages were offered nearly the whole of which were sold at firm to advanced rates. There has been a distinct revival in the enquiry for Ceylon teas, and as the quantities brought forward have not been at all excessive there has been a renewal of confidence on the part of buyers; prices have shown an improvement for all kinds, except perhaps for teas at from 6 1/2 l. to 6 3/4 l. which are slightly easier. Very high rates have again been paid for the finest specimens, which are only fine, however, in respect of being tippy teas as real quality is still conspicuously absent. Broken, of all grades and Pekoes at from 8d upwards have advanced considerably. Reports from Ceylon still point to large supplies for the next few weeks, and as the stock is equal to about three months' consumption, there seems little reason to anticipate a repetition of the rise which has characterised this time of year for the last two seasons.

THE CONSUMPTION OF TEA.—The British people now consume rather more than 5 lb. of tea per head each year. When the tea duty was reduced from 6l to 4d per lb., it was said that such a small remission would scarcely influence consumption. The thirty-fifth report of the Commissioners of Customs justifies Dr. Goschen's more liberal anticipations. In the year under review the imports showed an increase of over 23,000,000 lb.

CEYLON COCOA.—We reproduce elsewhere some remarks from the *Financial News* on the subject of the Ceylon cocoa industry and Ceylon tea. We presume that, apart from the financial aspect of the question, the future of Ceylon cocoa cannot have very much interest for readers of the *Financial News*. Perhaps we are to have a boom in Ceylon cocoa! The concluding remarks of the writers are as follows:—"The reason why so little information as to the possibilities of Ceylon cocoa reaches the investing public is that the holders of stock in the prosperous companies are satisfied with their securities, and prefer to keep the good things to themselves." Is an endeavour about to be made to induce some of these holders of stock to part with it for a consideration and will the investing public be asked to participate in the "good things" hitherto hidden from them?

THE CONSUMPTION OF TEA AND COFFEE.

(From the *Grocer*.)

Our anticipation of the effect of the reduction of the duty on tea to fourpence per pound, which we expressed last year, has been fully borne out by the substantial increase in the consumption which has already taken place. In fact tea has now become such a popular beverage that it is almost difficult to say to what extent the consumption will grow. In 1860 the average consumption per head of the population of the United Kingdom was 2 6/7 lb., in 1870 it reached 3 3/8 lb., in 1880 4 5/8 lb., and in 1890 it was over 5 lb per head. The weight of tea consumed in 1860 was only 77,000,000 lb., whilst in 1870, 1880, and 1890 it was 112,000,000, 160,000,000, and 194,000,000 lb., respectively. This wonderful increase was, of course, mainly due to the reduced cost of the article. We find, on reference to the books of one of the largest wholesale tea-dealers in London, that the average cost in the three periods mentioned was, omitting small fractions, 1s 10d, 1s, and 9 1/2d per lb. in bond, and the duty was in the first instance 1s, then 6d, and in the last mentioned year 4d per lb.; so that the cost on the market has fallen from 2s 10d to 1s 1 1/4 duty paid. As the duty was only reduced for part of the year 1890, the consumption for the first half cannot

fairly be compared with the corresponding period of 1889, but taking the six months ending June 30th last with the same period in 1889, when the duty was 6d. per lb. we find that duty was paid upon about 8,000,000 more pounds at the fourpenny rate; and as the market for tea during the early months of this year was very firm, the increase is even more remarkable.

There is another important element to bear in mind, that a pound of Indian or Ceylon tea will make more cups than the same weight of China produce; and it is marvellous how the consumption of the former has increased. For instance, twenty-five years ago the consumption of Indian and Ceylon tea was 25,500,000 (in 1865), against 120,000,000 from China, whilst in 1890 the consumption of Indian and Ceylon was 137,000,000, and the total from China had declined to 55,000,000 lb. There is a large field for grocers in this business, and, notwithstanding the reduced price, it is still a trade well worth cultivating. No one ought to know better what kind of teas suits the customer and the water of the district (which is very important) than the grocer who is on the spot. Of late we have heard that some persons, under the guise of philanthropists, are sending tea direct from the place of growth to the consumer at ridiculously low prices, with the view of cutting out the distributor in this country; but we do not think a grocer who knows what his customers' wants are need fear this opposition. When the price of tea was much higher than it is now, retailers had an opportunity of making a good profit on the sale. This by competition and other causes has been considerably reduced and the interest of the grocer has in many instances proportionately diminished, but the increase in the consumption should stimulate the desire to push a trade which even now bears a fair percentage of profit, and if energetically cultivated, would still contribute in a satisfactory measure to the weekly takings.

As a contrast to the substantial increase in the consumption of tea in the United Kingdom, it is interesting to compare it with that of coffee, which in 1864 was about 14,000 tons, and the average price in bond 74s per cwt. with a duty of 28s making 102s per cwt.; in 1873, when the duty was 14s, the price in bond had risen to 105s per cwt; and the consumption had only reached 14,433 tons; while last year the average price was, singularly, the same as in 1873, viz., 105s, and the duty 14s, or a total of 119s per cwt, but the consumption had declined to 12,810 tons. It is a well known fact that a pound of tea will make a larger number of cups to drink than the same weight of coffee, and taking into consideration the loss in weight which coffee sustains in the process of roasting, it will be seen that tea is now much the cheaper commodity. The imperfect manner in which coffee is generally made in this country helps to retard consumption, for in Holland, where it is almost the national beverage, it is roasted, ground, and made within a few minutes, in order that the aroma may be retained. In England it is roasted, and often ground, for weeks before it is required, and instead of being made by simply passing boiling water through the coffee, it is practically stewed, and undesirable elements are extracted which really spoil the liquor. This objection is met with at railway stations, &c., and travellers are led to entertain a dislike to a drink which on the Continent, where properly made is so generally used and appreciated. We have indicated some of the causes which have led to tea making such rapid strides in advance of its rival drink, coffee, and although the price of tea cannot be reduced in the same proportion as during the past twenty-five or thirty years, there is still room for a reduction or abolition of the fourpenny duty; and while we do not advocate this at present, we know there is strong pressure brought to bear upon the Chancellor of the Exchequer every year by the advocates of the free breakfast-table. When the duty is removed we shall be surprised if a further marked increase in the consumption does not take place. It is therefore highly desirable, as we have pointed out, that grocers should, by all means in their power, cultivate a trade which

though not bearing the same proportion of profit as formerly, is still likely to increase in quantity and, notwithstanding the various forms competition has taken, can still be made to bear a very fair profit and yield a good return to growers who are in a position to know their customers' tastes better than growers in foreign countries, and others who only affect this knowledge.

COCOA IN CEYLON.

(From the *Financial News*.)

The shrewdest of the Ceylon tea companies are wisely showing their appreciation of the maxim that no one should put all his eggs into one basket. Tea is of necessity, the most valuable export at the present time, and will probably continue to be the staple produce of Ceylon for another ten years to come. The West Kensington correspondent whose letters we published on Monday does not believe in "the enormous estimate for future Ceylon crops of tea." The most "enormous estimate" is that the output will amount to 100,000,000 lb. per annum in ten years time, which is about the quantity exported today from all the Indian gardens. Our point in discussing "Tea Shares as Investments" was the danger of the supply overtaking the demand. Quality rather than quantity should be the peremptory instruction of the London companies to their local managers. When the success of a plantation is measured by the fineness and lasting qualities of its leaf rather than by the extra thousands of pounds in weight sent out per annum, the Ceylon tea gardens will have established their equilibrium, and Ceylon tea will still hold a commanding place and a profitable price in "the Lane;" but, apart from tea, the natural resources of the island are sufficiently abundant to sustain the hopes of the investor in Ceylon securities. The disappointing results of Ceylon coffee and the quinine bark may fairly be said to have been counterbalanced by the success which has attended the experiments in the cultivation of indigo, of cotton, of a new fibre known in the market as "kapok" and, more especially, of the cocoa plant, of which the Ceylon variety is outstripping the best growths of the West Indies, not excepting the famous nut of Caracas.

It can only be a coincidence that the increasing consumption of cocoa in the United Kingdom should be occurring at the same time as the rise of the Ceylon cocoa industry. There is no possible connection to be found between the two facts that we are all drinking more cocoa than ever, and that the Ceylon supply is increasing, and obtaining the best prices in Missing Lane. It is possible that Ceylon cocoa is even now caviare to the general public. It has not yet become a special brand on the grocer's counter; it would be necessary to travel far afield to procure a sample with which to try experiments on one's palate. Its value, however, is recognised by the manufacturers of cocoa and chocolate in France and Russia, as well as in the British islands. Its prime cost is high, and it is bought, apparently, as an ingredient "too pure and good for human nature's daily food." Its commercial value consists, in fact, in its refining influence, which lends colour and flavour to a blend with cocoas of a poorer class. It can scarcely be said that the intrinsic merits of Ceylon cocoa account for the remarkable increase in the general consumption. At 4s or 5s per lb., the price at which the retailer could afford to dispose of it, the commodity would be almost out of the reach of the prudent housewife. The consumption of cocoa has, nevertheless, been a continually increasing item during the five years comprised in Messrs. Lewis and Noyes' last report. Their record, as regards the United Kingdom, runs, for the first half of each year, from 3,960 tons in 1887 to 4,780 tons in 1890, and 5,370 tons in 1891. The French—to whom cocoa is one or another of its forms is at once meat and drink—did not keep pace with our own people during the same period. The consumption in France for the first half of the present year was 6,910 tons, or only a trifling increase on the 6,070 tons of five years before. Stocks were large in France at the end of June; but prices were steady, and Ceylon cocoas still maintain their supremacy. The re-

lation which Ceylon prices bear to the commercial values of the West Indian product will be seen by the appended table, which we have taken from Messrs. Lewis and Noyes' August report:—

COMPARATIVE PRICES PER CWT.

	1891.	1890.	1889.	1888.	1887.
Ceylon	119/-25/	95/-105/	84/ 06/	90/-95/	90/-100/
Guayaquil (Arriba)	90/-97/6	50/- 85/	75/-80/	70/-74/	75/- 80/
Trinidad	64/-70/	65/- 69/	65/-70/	70/-75/	80/- 84/
Grenada	69/-83/	60/-63/6	59/-81/	60/-66/	69/- 73/

And this does not complete the tale, for at one time this year Ceylon "good rod" fetched as much as 133s per cwt. in open auction.

The cocoa industry in Ceylon, promising as it is, requires of its cultivator that "great capacity of taking pains" which Carlyle described as the quality of genius. It asks from all who know anything about it faith, hope, and charity. It makes a demand upon one's faith because five years must pass before it is possible to say that the outlay on the nurseries is likely to prove a profitable investment; it asks for charity in the sense that it must be tenderly nurtured upon a rich alluvial soil, somewhere by a river's brink, and under the shade of such shrubs as those which return their value in the "kapok" pool, or such trees as are being raised to come into one timber market as good teak wood. The three or four plantations which are cultivating the cocoa plant are even now only at the threshold of the good fortune which appears to await their enterprising proprietors. The root of the growth must have been originally at Caracas; it was transplanted to Ceylon, and, so far, it has increased and multiplied amazingly. The cocoa favours cocoa of Venezuela, the fruit of the equally celebrated growth in Mexico, the special varieties for which Trinidad was wont to be noted, have had to give way to the new competitor—the immigrant shrub which is fructifying in Ceylon. It involves some sacrifice, no doubt, to let one's money rest for half a dozen years until the cocoa plant matures. Everything seems to depend upon the suitability of the soil; but when the location is rightly selected, the plant is robust, and enjoys a remarkably long life. It is too soon to talk of the longevity of the Ceylon description of the *Theobroma Cacao*; but in Trinidad there are two thriving estates in which the cocoa trees are creditably reported to be over 100 years old. Perhaps the reason why so little information as to the possibilities of Ceylon cocoa reaches the investing public is that the holders of stock in the prosperous companies are satisfied with their securities, and prefer to keep the good things to themselves.

WITH A VIEW of encouraging the fruit industry in Victoria, the Railway Commissioners of that Colony have agreed to carry fruit at special rates, with a minimum of 1s for each consignment for any distance. This concession is a large one, as it will enable growers at a considerable distance to send single boxes of fruit to different persons at a very much reduced rate, provided the boxes do not exceed 1 cwt. in weight.—*Colonies and India*.
 IVORY.—When passing through the Exhibition, the other day, we noticed a splendid display of ivory in its raw and manufactured states. The "teeth," as they call elephantine tusks in the trade, included some very fine specimens, and it was apparent from some of them that *Dos Lucas* has been a great martyr to that ache which invariably reminds us that our masticating members are a plague to get, a plague to keep, and a plague to lose. One pair of mammoth tusks weighed 2 cwt. and was valued at 96l. Mammoth ivory, by the way, is not hunted for nowadays. It is found as an "alluvial deposit" in the rivers of Siberia, and is rarely fit for commerce, being too discoloured. The specimens at the German Exhibition, however, are, curiously enough, quite white. A couple of elephant's tusks are also shown which weigh 1 cwt. 3 gr., and which are priced at 175l. This lot came from the Kilima-Njaro district, the happy hunting ground of the searcher after ivory.—*European Trade Mail*.

PEPPER, TEA AND COFFEE CULTIVATION IN PERAK.

In the annual report of the Kuala Kangsar district, it is stated that

Syed Musa's pepper estate at Pasir Panjang, although not quite so well-kept and cared for as might be wished is making fair progress. Syed Musa, unfortunately, knew nothing of the cultivation of pepper when he commenced his plantation, and has therefore been very much in the hands of the Achinese coolies working on contract under him. The latter have not paid sufficient attention to the tying up of the vines, and the estate has not always been kept as clean as it might be, and this I find to be the case with most of the Malay plantations. Apart from these defects, vines are doing well. The estate is now about 163 acres in extent, and contains about 11,500 vines, of these 1,500 are grown on hard-wood posts and the remainder on "dedaps." The first vines were planted about two years ago, and there are now 5,000 in bearing, about three of pikils pepper having already been gathered. Up to the end of the year the Government had advanced \$1,780 on the estate. Advances are to be continued up to \$3,000, and altogether 16,000 vines are to be planted. The Government originally provided Syed Musa with the means of opening this estate with a view to encouraging other natives in the district to take up land for the cultivation of pepper and this object has certainly been attained, during the year 600 acres, mostly in small blocks varying from one to five acres in extent, having been taken up for this purpose. Some of the plantations are doing very well particularly those belonging to Chinese and Achinese who possess a little capital. The Perak Malays, as a rule, are not so successful, lacking both the perseverance and energy requisite for the cultivation of pepper and having a rooted objection to finding any money in their plantations unless it can be borrowed from Government. After Syed Musa's the largest pepper estates are two belonging to Kong Lim, which are 10 and 30 acres in extent respectively. The smaller of the two, on which the vines are trained against hard-wood posts, is worked with Chinese labour, but on the 30-acre block the pepper is being grown against dedap trees, and the labour performed by Achinese working in the tribute system. These two estates were both started about the same time and on the same soil, it will therefore be interesting and instructive to compare their progress and ultimate success. Kong Lim does not appear to have much difficulty in obtaining Chinese agricultural labour, but he complains of the short hours the coolies work. The men he is now employing insist on working for only eight hours a day, as in the mines; and to make pepper pay he says it is necessary that they should work for at least 10 hours. The Government experimenter at pepper plantation at the foot of Gunung Pondok, as was anticipated, has not proved a success, the soil, although very rich, being quite unsuited for the growing of pepper. In the other Government plantation, at Padang Rengas, the vines appear to be in a very flourishing condition. This plantation is about 13 acres in extent, and contains several large nurseries of pepper plants which are now ready for planting out, a large number having already been supplied to Kong Lim and other planters in this district. The Cicely Tea Estate was let in June to Messrs. Lim Ah Koi, Lu Peh and others; and in July the Horntage Tea Estate was relet to the same people. During the last year the number of coolies employed on Messrs. Hill and Rathborne's Liberian coffee plantation, at Kumming, has been increased, and a vast improvement effected in the general appearance of the estate. Several fields, which, for want of labour, had to be abandoned, have now been reclaimed, and I am informed that the whole of the original clearing, about 258 acres in extent, will be cleared and planted up by March next and that the first picking will commence about October.

COCO-DE-MER.

There is in the cabinet of Mr. Joseph H. Wright of this city a very fine specimen of the Coco-de-Mer, a curious nut produced upon the palm tree which

grows in only one spot in the world, the Seychelle Islands. This specimen has attracted a great deal of attention and has been loaned by Mr. Wright for exhibition in this and other cities. We (*American Crocer*) are indebted to Mr. Wm. Saunders, Superintendent of the Public Gardens, Washington, D. C. for the following interesting description of the palm tree which produces this remarkable fruit:

LODOICEA SECHELLARUM.

This palm produces the celebrated Double Coconut or Coco-de-Mer, which, until about 140 years ago when the trees were discovered upon which they grew, was only known as a large nut found floating in the Indian Ocean and near the Maldive Islands. The nuts were only found destitute of their husks, and mostly with the internal part decayed. They were supposed to be produced on a tree growing in the sea, and Chinese and Malay sailors affirmed that the nuts were borne upon a tree deep in the water, which was similar to a coconut tree, and was visible in placid bays, upon the coast of Sumatra and adjoining coasts, but that if they sought to dive after the tree it disappeared.

Negro priests declared that it grew near the island of Java, where its leaves and branches rose above the water, and wore the habitation of a monstrous bird, which carried off elephants and tigers to its nest, so that mariners of the Indian Archipelago carefully avoided that spot.

Great value was also preferred upon these nuts for medicinal properties, all of which is equally a matter of historical fact.

The Seychelles lie to the north of Madagascar, in about 5 deg south latitude. It is in this group only that the palm is found, and among them only in the isles of Praslin, Curieuse and Ronnd Island. These are within half a mile of each other and are mountainous and rocky.

The *Lodoicea* attains a height of 80 or 90 feet, and is surmounted by a beautiful crown of winged and palmated leaves; the trunk is from 12 to 15 inches in diameter and very flexible; the leaves are large, 20 feet long and 10 to 12 feet in breadth, and even larger. The straight and slender stem, when surmounted with a heavy crown of leaves and fruits, has a strong leverage on the roots, which are strengthened for this office in a peculiar manner; the base of the stem is rounded, and fits into a natural basin or socket, about 30 inches in diameter and 18 inches in depth; this basin is pierced with hundreds of small oval holes about half an inch in diameter, with hollow tubes corresponding on the outside, through which the roots penetrate the ground on all sides, but never become attached to the basin or bowl, their partial elasticity affording a certain amount of play to the stem in violent gales.

The tree requires 100 years before it attains its full growth, and thirty years is the shortest period before it pushes out its flower buds. It requires ten years from the first appearance of the flower till the fruit reaches maturity; it bears only one cluster of flowers yearly, yet it will often have ten in bloom at once; it has flowers and fruit of all ages at one time.

The fruit is a drupe, of an olivo green color, and generally double, sometimes triple, and even quadruple, and frequently attains a length of 18 inches, with a circumference of 3 feet, and sometimes weight 40 to 50 pounds. It is the largest fruit which any known tree produces.

The immature fruit is easily cut with a knife, and affords a sweet and melting aliment, of an agreeable taste. When it is ripe it drops on the ground, and is no longer fit for use.

The unopened leaves of young plants are used for making hats and bonnets; the splitting of the leaflets is difficult, but is performed with considerable skill by those accustomed to the work. Various useful and extremely beautiful articles are made of these leaves, and mats of great durability are manufactured of the strong leaf fibres. The leaf stalks are used for fences and for rafters of houses; they are strong and very durable. The trunk is so hard as to be difficult to cut with an axe; split in two and hollowed, it is used for water gutters, and is almost imperishable.

THE ANNUAL REPORT OF THE KINTA DISTRICT, PERAK,

notes:—

Land and Agriculture.—During the year 1,649 acres of land were alienated—mining 1,550, agricultural 99. Agriculture in the district, it will be seen from this, makes little progress except in the shape of small gardens. It is true there are constant applications from Malays for forest land, for the purpose, they say, of planting coffee, pepper, and nutmegs, but on enquiry these applications turn out, almost without exception, to be put in for the purpose of evading the Government order prohibiting the selling of "rimba" for ladangs, and where the land has been given, and the heavy forest felled and destroyed, the land is always abandoned after one crop of dry padi has been taken off it, and the applicant surrenders the title, saying the coffee which he never planted would not grow.

To prevent this I have during the year always insisted on natives who apply for "rimba" land finding security that they have sufficient capital and *bona fide* mean to plant the land before I grant it. The average above-mentioned is small, but it has been issued to men who will really work it, and, considering the greater attractions held out by the mines to invite investors, it cannot be considered unsatisfactory. A great portion of it is being planted with Liberian coffee and pepper, but it is too soon yet to express any opinion as to whether these small plantations will be a success or not.

Mines.—The number of mines now registered in the Kinta Land Office as held under Leases and Agreements for Leases is 850, and comprises an area of 10,948 acres. During the year 1,550 acres of new mining land were granted to 62 applicants, and that number of titles issued, and at the end of the year 47 further applications were registered in the District Land Office, and the land applied for is being demarcated and surveyed.

The alluvial mines are as a rule, well worked, but there are several mines, notably those of His Highness the Sultan in Kampar, of Joh Domba, in Sungai Raya, and of Fu Chuan at Lohat, which have been worked in the most wasteful way, small pits being sunk in their land by men who have no capital to go deep enough, and are only able to lift a small portion of the tin-bearing strata, the balance being afterwards left and covered up with over-burden from the adjoining ground. The well known Sorakai mine, worked by Fu Chuan for Captain Ah Kwi, has been spoilt in this way, as after getting down over 100 feet through the wash without reaching the bottom, the engines were not sufficiently powerful to pump any deeper, and some sort of winding gear having become necessary to lift the wash-dirt at a profit the Chinese, sooner than spend the necessary capital on machinery, abandoned the mine, and have since filled it up by sluicing sand from the adjoining hill into it. Legislation of some sort has become necessary to prevent another case of the sort occurring. The land of His Highness the Sultan in Kampar, I am glad to say, is now being better worked, owing to a change in the agent in charge of his mine. There is little more to be said as regards the alluvial mines, but a remarkable find of tin ore at Sayak is worthy of mention. The mine belongs to the Dutch Panglima Kinta, and is let to a Chinese towkay who works it on the co-operative system. Late in the year his coolies sunk two holes, one thirty feet square and the other twenty-four feet square. In the first hole in 12 days 11 men lifted 450 pikuls of tin sand, worth \$8,100, and in the second 23 men lifted in 5 days 200 pikuls of tin sand, worth \$3,000. Nine-tenths of this goes to the coolies, who have in a few days become comparatively rich men.

There are 56 steam pumping engines now in the district, of which 42 were at work at the end of the year.

The year has been remarkable for the numerous discoveries of lode out-crops made in the district, and the attention given to that branch of mining.

A remarkable change has come over the transport of the district during the year owing to the Chinese having almost entirely abandoned elephant transport and substituted wheel-barrrows for them. The change

was brought about by the elephant owners demanding such exorbitant prices for the use of their animals that the Chinese refused to submit to such extortion any longer, and introduced wheel-barrrows, which are cheap and work very well on the jungle path.

NEW MINERALS DISCOVERED IN KINTA DISTRICT DURING 1889-1890, AND LOCALITIES.

1. **Asbestos** (R. O. S. Q.).—This mineral was found associated with ferruginous quartz in lode-stuff at Haji Latif's mine, Kledong. It is in very small quantities.

2. **Cerussite** (carbonate of lead).—This mineral was also found in Haji Latif's mine at Kledong, associated with lode-stuff. It is not in sufficient quantities to be of any commercial value.

3. **Pyromorphite** (phosphate of lead).—This mineral was also found in Haji Latif's mine at Kledong, also in several of the different lodes in Kinta.

4. **Apatite** (phosphate of lime).—This mineral was first found at Tempurong, near Gopong; after this a big dyke of it was found running through the limestone hills at Si Luah, Tambun. This phosphate, treated with sulphuric acid, which could be obtained from the ore smelted by the lode-mining companies, forms a very valuable manure. The apatite at Tempurong occurs as small veins and leaders running through the country limestone, and is very rich in tin.

5. **Wolfram** (tungstate of iron and manganese).—This mineral was first found in the Kilian Repoh lode at Tambun; it occurs there in large quantities; since then it has been found to be associated to a large extent with the tin ore in Kinta. The present low price of this mineral would not admit of its being exported at a profit.

6. **Bismuth** (native).—A small piece of this valuable metal was found in the limestone hills at Tambun; no trace of it has been found since.

7. **Fluor-spar** (fluoride of calcium).—This mineral was first found at Lohat; since it has been found associated with the lode taken up by Mr. Taylor at Kodong.

8. **Sapphire** (pure alumina).—Sapphires have been found at Sungai Raya, but they have no commercial value, although of good colour. They are very opaque, which renders them useless as gems.

9. **Chalcedony** (silica oxygen).—This mineral has also been found in Sungai Raya, and some of the varieties of chalcedony are precious stones of value, such as agate, onyx, and carnelian.

10. **Gold**.—This has been found in small quantities at Ulu Tekah; it has not been worked.

In the Kinta *Monthly Report* for July, it is stated:—

On the 3rd Mr. Marks, Superintendent of Government Plantations, arrived and inspected the lands at Pusing planted by Raja Mahomed and his followers.

As Mr. Marks tells me he has nurseries of coffee, pepper, coconut, and other plants at Kuala Kangsar, from which he can supply young plants at low price. I have sent notices to that effect to the Penangis, and have already had several applications for plants.

An Italian marble cutter named Banardo applied for permission to work marble at the Ipoh quarries. I gave him the permission. He states that the marble is of the best quality, and easily worked. There are three sorts in the quarry—pink, white and blue veined.

PROPOSED QUININE-FACTORY IN JAVA.—Mr. P. van Leersum, assistant director of the Government cinchona plantations in Java, has received permission from the Dutch Indian Government to proceed to British India on behalf of the Bandoeng and Soekboemi Agricultural Association for the purpose of investigating the manufacture of quinine in the Indian Government factories, and with the ulterior object of establishing a quinine-factory in Java.—*Chemist and Druggist.*

Correspondence.

To the Editor.

MR. MAITLAND KIRWAN'S PATENT TEA PAPER.

Billiter Square Buildings,
London, Aug. 13th. 1891.

DEAR SIR,—You may have noticed by Messrs. Wilson, Smithett & Co.'s last circular that tea still continues to come forward in the new patent paper lining and is found to arrive in perfect order.

The last consignment I had from Elkadu in this paper proved very satisfactory; the memo so because my head superintendent wrote me saying he feared it might not arrive in good order owing to its having been packed in very wet weather. It was however just the test I wanted to prove that the paper was not merely a fair weather material. I may mention that this tea was valued by an expert along with a sample out of the same break packed in the ordinary lead lining; and without knowing which was which, he pronounced the sample (paper packed) the fresher and better of the two; the lead lined presenting somewhat of a tinny flavor.

I think there can be no doubt that a certain amount of corrosion must be imparted from the lead linings which to some extent must affect the quality. The paper linings, of course, will obviate this, and what with a saving of nearly 50 per cent I have no doubt these linings will continue to command themselves to the planter and proprietor. I am a little surprised that your Planters' Association have not taken the matter up, after being supplied with samples of the paper, but, no doubt, now that it has been proved a genuine success, they will move in this business.—Yours truly,

J. M. MAITLAND KIRWAN.

(Extract from Wilson, Smithett & Co.'s Circular.)

In the Board of Trade Returns given below we note a satisfactory expansion in the exports of Ceylon tea, which seems to indicate a wider knowledge and growing appreciation of its excellence. One or two breaks of Ceylon were included in the sales packed in patent paper lined packages, and apparently arrived in very good order.

A WORD OF WARNING TO CEYLON TEA PLANTERS.

London, August 21st.

DEAR SIR,—The Ceylon Tea Industry taken as a whole is apparently well on its way to ruin. Let those whom it may concern take warning in time. The sole cause is the attempt to make too much tea. A very short continuance of the late style of picking and manufacture will relegate Ceylon teas to the place lately occupied by the lowest kinds of China; and Ceylon tea instead of being a name to attract will repel all who want tea of good character and agreeable flavour. The teas at present on this market from Ceylon are to a very large extent badly made, inferior in strength and quality and overgraded; consequently prices are realized which must leave a serious loss to planters in many cases and under the most favourable circumstances but very small profits. This in itself may act as a remedy, but it will take time. In the meanwhile it behoves everyone who has the interests of the Ceylon Tea Industry at heart and more especially the Planters' Association to urge planters not to be tempted by heavy flushes and increased estimates and yield to make more tea than they can properly manufacture.—Yours, &c.,

CAVE.

THE TALGASWELA TEA CO.

Aug. 25th.

DEAR SIR,—It would be well if the Directors of the Talgaswela Co. published the whole of Mr. Grigson's report, so that present and intending shareholders might really read for themselves what Mr. Grigson did write, instead of having their minds exercised with the scraps of the report given in the papers. One part of the scraps seems to have led a shareholder to indulge in the funny suggestion that the series of patches of bad planting was not bad planting at all, but the result of poisonous roots, as if an intelligent V. A. like Mr. Grigson would have wasted time and paper and ink in describing a few blemishes in a field, that anyone may note in a new tea clearing. Let me refer to the scraps even as to what Mr. Grigson did write on this matter. Notwithstanding " (what?) there is great irregularity in the growth and development of the tea due to planting by village labour." I, for one, and I am pretty certain no sensible man, would believe, that such "great irregularity in the growth and development of tea" is caused by poisonous roots, but simply by bad planting. The use of the "red horring" is not confined to cookery!—Yours truly,

MYSTIFIED.

THE TALGASWELA TEA COMPANY (LTD.).

Colombo, Ceylon, Aug. 28th.

DEAR SIR,—The writer of the letter in your issue of yesterday need not long remain "mystified," as I am quite sure the Secretaries of the Company will be only too happy to supply him, or any other applicant, with a copy of Mr. Grigson's report, which, I believe, has already been sent to every shareholder in and out of the island. I may tell him that the report covers five pages of printed foolscap, and it is hardly to be expected that papers would give any company a free advertisement by inserting so lengthy a document—a document, too, intended primarily for the information of the shareholders. Other companies do not usually publish their V. A.'s reports, but no doubt the directors of the Talgaswela Company will deviate from the general custom, if "Mystified" sends a cheque to cover the expense of so doing.

As to the other point referred to by your correspondent—the irregularity in the appearance of the tea—Mr. Grigson is of opinion that it is due to "village labour," while the manager of the estate Mr. Broadhurst (who has been a planter in the Galle district for 12 out of 22 years in the island) attributes it to "immature seed." It is no uncommon thing to find experienced men differing very widely on planting matters, so the present conflict of ideas is hardly a subject of much moment to the shareholders. What is of more interest is the fact that the V. A. reports that this year's crop has been sold at an average of 46c. per lb. nett, "which is a better result than would be expected from the low-country generally and is therefore a feature of distinct promise." He also states that the yield next year should be about 180,000 lb. from 495 acres four years old and 196 acres three years old, equal to an average of 264 lb. per acre; and the yield for the following year (1893) is estimated by another competent authority at 450 lb. per acre, giving a total of over 300,000 lb. Bearing in mind the "exceptional advantages" (Mr. Grigson's words) Talgaswela enjoys in regard to labour, the "easy and inexpensive" transport facilities, and the fact of there being "500 or 600 acres available for the further extension of the tea industry," I shall not be surprised to find "Mystified" in the market for

shares, even though he has to pay from 30 per cent to 40 per cent premium. I may add that I for one have bought more shares since the circulation of Mr. Grigson's report.—Yours faithfully,

WHISKEROSO.

[Authenticated.]

A PRACTICAL TALK ON TEA MANUFACTURE.

Sept. 3rd.

DEAR SIR,—Your issue of 1st instant contains a good deal of interesting matter to tea planters:—

1. Mr. Hughes' remarks to your London correspondent regarding tannin in tea as being the test of the market. No word, in Mr. Hughes' remarks or in your leader, appears as to *flavour*. Any expert will tell you that that is the true test of tea.* Strong teas are the result of quick withering in a warm climate because one day's plucking is rolled the next day, and therefore the withered leaf is not sufficiently tough; whereas at a high elevation and at a lower temperature the withering process is slower and more natural so that the contents of the cells of the leaf are released without the texture of the leaf or the cell walls being bruised. You say, tannin is said to be scarcely "ever present to any extent in the first cup of infusion obtained from tea if the time allowed for it to stand be limited to some three minutes or so only." Just so; so that tea tasters do not wait for the extract of tannin. When tannin is unduly present the tea are classified as "rough" or harsh.

2. Mr. Davidson's remarks.—Here we have a true expert speaking, and his remarks are worthy of all attention. Stowing is the result of rolled tea spread *thickly* on the firing trays and not the result of low temperature used in the drier. Slow firing is the correct method to desiccate the tea, but when a planter is pushed for time he cannot afford to do it. Let a machine be adapted to finish large quantities of leaf with a minimum of firewood. There is a good deal of truth in the effect of steep rocky land on tea giving it a "high-grown" character. Udugama and Galle bring "pucka" low country, does not come under that category, and I have often heard that tea from that part of the island has a distinct character of its own.†

3. "Wanderer's" Notes.—The remarks as to the absence of the planter from the factory resulting in better tea is correct, barring the chaff implied. Your Talawakellie correspondent is not consistent. He first of all "joins issue" with Wanderer, that is seeks to correct him. Then he says "he, Wanderer" talks about the absence of the planter from the factory as possibly conducing to better made tea," and then in the next line agrees with him that "tea is not made in the factory"!! The Talawakellie correspondent may say what he likes, but when all departments in the factory are strained by press of leaf; when coolies have to tear ahead, and Sinhalese called in to help during the rush in May;—surely the tea cannot have the attention which it gets in August. In August a planter can pluck, wither, roll, fire, pack, calmly and easily;—therefore better tea is the result. Many men say that it is all humbug for the brokers to call out about bad tea when large quantities are coming in, but the majority of planters know what goes on when to save their estimates leaf *must* be harvested, when the rush is on, and to that end the flush

must not be allowed to run away. The cry about inferior quality of tea, and insufficient labour becomes a screech in the agony of a "May" rush, and sinks almost to a whisper in the easy days of August. Your Talawakelo friend must have laughed in his sleeve when he wrote the following: "I would say rather labour is plentiful because more coolies have come in from the coast." Ha! Ha! All our troubles are oaded—more coolies have come in from the coast! I wonder who is the man whom your Talawakelo correspondent knows who "rarely spends over an hour a week in the factory." His teas may be good, but that argues the excellence of the tea maker and the wisdom of the tea-maker's master in keeping out of the way, but not that the factory coolies will do better without the *airai* going near.

4. Then in the issue before the one under notice we had some hard criticism from India. All right, we can afford to read it and laugh over it. The days are gone when Ceylon planters used to brag. That's gone out with coffee. There is no brag now, but a hard grind to make ends meet; and if great progress has been made, then Indian sneerers cannot aff of what is known everywhere; that we have built a new industry on the ruins of another. The Indian tea planters were always tea planters and have been at it for many years; but the Ceylon men have risen from the ashes of a former great ruin, and if they are not making their fortunes, they have held their own and pushed ahead by steady determination, energy, combination, and advertisement. PRACTICAL MAN.

UNFERMENTED TEA SELLING WELL.

DEAR SIR,—A planter of many years' experience of tea told me a short time ago that he never allowed his tea to ferment, but put it into his driers direct from his rollers. Reading a treatise on the subject of Fermentations, I noticed the following paragraph:—"Fire your tea immediately after it is rolled, and after infusion note flavour of liquor and colour of out-turu. The liquor tastes harsh, pungent and raspy, and is quite *unpalatable*, it further wants body."

In the face of these remarks I am surprised to find the unfermented teas, made by the planter I refer to, have realized an average of about 47s per lb. during the present year. Can any of your readers give me any information on the subject?—Yours faithfully, PUZZLED.

[We can imagine such teas being pungent and valued for this quality, but if wanting in body it is not likely they would sell at the price mentioned. *Over-fermenting* is certainly injurious.—Ed. T. A.]

COFFEE GROWING IN THE VANU is described by Mr. J. P. Lewis, A. G. A. of Mullaitivu, in his Diary for 1890, as follows:—

June 25.—I turned off on the road also to inspect Kachelikunadu, a good village. Here in one compound I saw several coffee trees in bearing—a curious sight in the Vanu. The owner (the chief cultivator Vellivayalkulma) said they had been planted by his grandfather, and that formerly there was a whole garden of coffee in this village; even now the berries are sometimes sold. This is the place where Pandara Wanniya was finally defeated by the British troops under Captain Drieborg in 1803. I made inquiries as to the exact spot where the fight took place, and the man referred to above pointed out to me a part of the village clearing under some tamarind trees, which he said he heard his grandfather and other people describe as the scene of the fight.

* For drinking unmixed, no doubt; but for mixing purposes strength has been desiderated.—Ed. T. A.

† Like that of the Terai and Doovers in India.—Ed. T. A.

ECHOES OF SCIENCE,

The effect of adding aluminium to steel ingots has recently been discussed by the American Institute of Mining Engineers, and, according to Professor Arnold, its effect in rendering steel castings perfectly sound is very marked. It is twenty times as powerful as silicon, and the resulting steel is tougher. By using it, manganese can be discarded, and a considerable saving in time and fuel effected.

The new lake which recently formed in the hollow of San Diego County, California, turns out to have been fed by the Colorado River which, overflowed its banks owing to the melting of the winter snow in the Sierras of Colorado, Utah, and Nevada. As evaporation proceeds at the rate of 100 inches a year in this region, it is expected that the lake will only have an ephemeral existence.

In a study of the flora of Greenland, Sir J. D. Hooker came to the conclusion that it was European rather than American, and Professor E. Warming has since tried to show that it is American rather than European. As usually happens in the case of two such conclusions the truth lies between them, and Professor Nathorst now points out that while the east of Greenland nearest to Iceland contains European forms only, the east next to America yields American forms, and at the Southern extremity the flora partakes of both characters. On the whole, however, Sir Joseph Hooker seems to have been right, the flora being rather more European than American.

The flora of an insular country comes as a rule from the nearest land, and in this respect is like the human population. Thus in Britain we have a southern flora opposite France, a Germanic flora on the east coast, a Lusitanian or Peninsular flora in the south-west, and in the extreme west of England there are two American plants unknown in any other part of Europe. The seeds have probably been brought hither by winds, tides, or birds. Since the close of the glacial epoch a replanting of our shores with various forms from the nearest coasts has been slowly going on, and is still in progress.

According to a German scientific journal the place where thunderstorms are most frequent is Java, which has an average of no fewer than 97 thundery days in the year. Next to Java comes Sumatra with 86, then Hindostan with 56, Borneo with 54, the Gold Coast with 52, and Rio Janeiro with 51. In Europe the list is headed by Italy with 38 days, Austria with 23, Baden, Wurtemberg, and Hungary with 22, Sillesia, Bavaria, Belgium with 21, Holland, Saxony, and Brandenburg with 17 or 18, France, Austria, and South Russia with 16, Britain and the Swiss Mountains with seven, Norway with four, and Cairo with three. In Eastern Turkestan and in the extreme northern parts of the world there are few or no thunderstorms. In fact the northern limit runs through Cape Ogley, Iceland, Novaja Semlja, and the coast of the Siberian Sea.

It is clear from these statistics that heat is necessary for the production of thunderstorms; hence it is that they are most frequent in the hottest summer months, such as July and August. But heat alone is evidently not everything; there must be moisture too, and in the form of clouds. Cairo, for instance is a very hot place, but being dry and cloudless it is seldom visited by lightning.

It is well-known that a mixture of lime and sulphate of copper has been used as a germicide in diseases of the vine, potato, and tomato. M. Aimé Girard has also applied this remedy to beetroots threatened with attacks of the fungus which causes the disease known as "Peronospora Schachtii." A three per cent. solution of copper sulphate is mixed with a three per cent. water of lime, and the mixture is sprayed on the beet from a tank carried on the dresser's back. Copper hydrate is the effective agent, but its use had better be watched with care, for certain cereals are known to assimilate metallic salts, and beet-sugar is now consumed in large quantities by children.

On the 6th of June last a shower of stones fell at Pel-et-Der in the Department of the Aube during a violent hail-storm. These unwonted drops have been examined by a geologist, who finds them to be of chalk from Chateau-Landon, which is 150 kilometres

from Pel-et-Der. It is believed that the stones were lifted into the atmosphere, and conveyed by a whirlwind.—(*Globe*.)

CACAO, COFFEE, AND COCA IN PERU.

From a recently-published report by Consul Mansfield on the Agricultural Condition of Peru, dated Lima, October 8th, 1890, we learn something of the value of the above-named plants in that country.

Of Cacao, or Cocoa, as we usually call it (*Theobroma Cacao*), we are told that up to a recent date its cultivation in Peru seems to have been confined more especially to the Transandinian slopes, in the province of Convencion, in the department of Cusco; not, however, in sufficient quantities to supply the markets of the southern departments of the Republic. The Cacao produced is of a superior quality, and could compete advantageously with the best descriptions raised at Socorro and in Venezuela. The excellence of the bean is, however, rather due to the geological and topographical conditions of the Valley of Santa Ana than to the efforts of the cultivators. The Cacao goes by the name of Cusco Cacao, but owing to the cost of production, distance from the sea, and deficiency of transport, cannot compete in price with that imported from Ecuador; consequently, the production and consumption does not extend beyond what is requisite for the local demand. Cacao of good quality has also always been raised in the province of Jaén, in the department of Oajamnia, and the cultivation of the plant extends towards the sea-board in the north of the department of Piura; but upon so limited a scale as scarcely to amount to more than an experiment.

With a more extended development, Cacao could easily be produced in sufficient quantities for the internal consumption of Peru, displacing export from abroad, and, perhaps, even competing in foreign markets, a future for the industry which appears more than probable, when the contemplated irrigation scheme in the department of Piura shall have been carried into effect.

With regard to Coffee, it is said no better quality is produced in the world than in Peru; more especially that raised at Chauchamayo, in the department of Junin, and in the province of Carabaya, in the department of Puno. The production amply suffices for the internal consumption, notwithstanding that the latter has much increased during the last few years. Small quantities, during several years, have been exported to Europe, which, on account of the quality, found favour in the market, and fetched good prices, with the result that foreigners are beginning to settle in Peru as Coffee planters upon quite a considerable scale. The coast valleys, as well as those in the Transandinian districts, furnish a favourable field for the plantations. The amount of the present production is not estimated. In 1888, 27,107 kilos. were exported from Callao, and 25,650 kilos. were imported from Guayaquil through the same port.

The Coca plant (*Erythroxylon Coca*) so well known for its anæsthetic and medicinal properties, is indigenous in Peru, and is largely consumed by the Indians in the Republic, where it is cultivated for exportation. No other country, indeed, competes with Peru in the quantity exported. Two establishments exist for preparing the leaf—one in Lima and one in Callao. During the last year, 1730 kilos. of Cocaine were exported to Europe, principally for Germany. No statistical data are forthcoming concerning the amount of production, but in the year 1888, 28,000 kilos. were exported through the port of Callao.—(*Gardeners' Chronicle*.)

"PRACTICAL LANDSCAPE GARDENING."—Under this title Messrs. Putnam, of New York, announce the speedy publication of a work by Mr. Samuel Parsons, Superintendent of Parks in the City of New York.—(*Gardeners' Chronicle*.)

THE EGG-PLANT.—As some of the neglect of the egg-plant is doubtless due to the fact that cooks are not familiar with it, the following recipes for cooking the fruits are recommended by the experimenters at Cornell as reliable: (1) Cut in slices crosswise, not over a half inch thick, and parboil in salt water about fifteen minutes; then remove, and fry in a hot spider in butter and lard. (2) Cut in slices a quarter or a half inch thick and lay in strong brine for two hours; then wash very thoroughly; sprinkle with brown sugar, pepper and salt, and fry slowly to a dark brown. (3) Cut in two lengthwise, remove the seeds and pulp, and fill with dressing made of half a teacupful of bread crumbs, one teacupful of butter, and salt and pepper to taste; lay the halves side to side in a dripping pan add a little water, and bake nearly an hour. (4) Pare, cut in thin slices crosswise, soak in salt water for eight or ten hours; dry on a towel, dip in beaten egg, and roll in bread crumbs, then fry slowly in hot butter until the pieces become a rich brown; serve hot. *American Grocer.*

CINCHONA IN JAVA.—From the report of the director of the Government cinchona enterprise in Java for the second quarter of 1891 we learn that from the middle of April to the end of May drought was experienced. June was wet, but only occasionally heavy showers fell. The weather was not favorable for the young plants put out in March and April, but the older plants made exceptional growth in response to the alternate heat and wet. The upkeep of the plantations during the wet season was confined to keeping clear the young gardens, with the view of assisting the small plants in their struggle with the growth of weeds. On the setting in of the dry weather the thorough working of the surface of the soil by means of hoes was commenced. Working of the ground was speedily carried out in young plantations, with a view to protect them from the drying of the soil in the expected severe east monsoon. The continuance of working of the ground during the rainy season has had the good result of diminishing considerably the root disease, which now prevails only at Nagrak. It may be admitted that the root disease has its origin chiefly if not entirely in the excessive moisture and incomplete aeration of the soil. By the maintenance of a dense growth over the ground the superfluous moisture of the soil is evaporated through the leaves of the cultivated plants and the weeds, and thus also the chief factor of the origin of the root disease is removed. The aim is to cause the evaporation of the soil moisture by the cultivated plants alone, by means of close planting. At Nagrak, in order to hasten the drying of the soil and thus combat the root disease successfully, the working of the ground was not carried out again in the second quarter. During the first half year of 1891 some 200,000 half kilograms of bark were gathered, consisting both manufacturer's barks of moderately high quinine contents and of pharmaceutical barks in the desired quill form. In consequence of the great fall in the price of cinchona bark in the European market, whereby the bark of *C. succirubra*, since it cannot be harvested in quill form, can no longer be brought into the market with any profit, or only little, a considerable change has taken place lately in the harvesting of this variety of cinchona. Crowded plants, which should of necessity be removed in order to give more light and room to the over-shadowing trees, are no longer dug out, but cut off near the ground, whilst no more bark is gathered from the stem, except what can be cut in quill form. If in the future no root bark and also little or no stem bark of *C. succirubra* is packed in bales and despatched, this will have a great influence on the

quantity of bark gathered, but the average value of the crop will thereby be considerably increased. By the end of June 123,307 half kilograms of bark of this year's crop were despatched to Tadjong Priok. On 2nd April, 14th May and 11th June bales of bark of the 1890 crop were held in Amsterdam. The unit price for manufacturer's bark amounted at these sales to 5½, 6½ and 6½ cents per half kilogram. As a consequence of the mild east monsoon in 1890 the blossoming of ledgerianas was small, and the crop of seed of this variety of cinchona therefore promises to be small. In the latter months of this year it will be possible to hold sales of small lots of ledgeriana seed. The total number of plants in the Government gardens at the end of June was 3,791,600, viz.:—In the nurseries—490,000 ledgeriana (including 20,000 grafts), 413,000 succirubra: total 933,000. In the open—2,169,000 ledgeriana (including 270,000 grafts and cuttings and exclusive of the more or less 3,000 original ledgerianas), 2,200 calisaya and haskarliana, 633,000 succirubra and caloptera, 52,900 officianalis, 1,500 califolia: total 2,858,600.

Cocoa is an article which ought to be grown here [Hawaii] and exported. The cocoa of our own high-priced and always in demand. There are a few cocoa trees growing on these islands, but no attempt has ever been made to prepare the article used in confectionery. On page 249 a correspondence gives a detailed description of the best mode of cultivation and of curing the berries. It seems to us that a small farm of ten to twenty acres, located on the line of the Oahu railroad, where artesian water for irrigation can be supplied, would be just the locality. Bananas help to pay current expenses till the cocoa orchard comes into bearing and perhaps even after it. The subject treated of by our correspondent is well worth the attention of those having the means and the opportunity to engage in this pursuit, in a desirable locality, which, if well located, must always be a safe real estate investment.—*Planters' Monthly.*

OUR NORTH TRAVANCORE correspondent writes to us, under date 23rd instant:—"While reports are coming in from other planting districts about the scarcity of labour, and the friction which is the natural outcome, we find ourselves here with labour to spare. In May I had to send away a gang of 30 coolies who came and offered themselves,—they went on to the next Estate and were not wanted there either. At the end of this month I shall send away about 50, much against their own will! I know of more than one Estate here which does not give any advances whatever, and the labour supply for the last five years at any rate has been ample. My own coolies return to me year after year without an anna in the way of advance. They are recruited partly in Trichinopoly and partly in Tanjore. This shows what combination even in a small district with only 2,000 acres under cultivation can do. The Travancore Planters' Association has divided the estates which subscribe to it into three sections, North, Central, and Southern, and the facilities for procuring labour differing slightly, rates of pay for each district have been separately settled, and every planter has bound himself to make no further change unless allowed to do so by the Association. At the last General Meeting of the Association, the correspondence with the South Mysore Association on the subject of combination was read, and our Secretary was asked to try and arrange an early meeting of delegates from every Association in Southern India. So far we have not heard what has been done, but as far as we are concerned, we intend to keep hammering away at the subject until a United Planters' Association is formed for the whole of Southern India. As a step in the right direction, our local Association has become affiliated to the 'Travancore Planters' Association.' Last week when I wrote, the monsoon seemed to have gone for good, but yesterday it commenced raining and looks like continuing."—*Madras Times.*

THE PROPOSED PLANTING ENTERPRISE IN PERU.

In a letter which we publish today, as well as in productions previously published, a former well-known, intelligent and experienced Ceylon planter sings the praises of the land of the Incas, from its Pacific shores to its Trans-Andean expanses of exceptionally fertile soil under a climate (which, with a characteristic ebullientness of disappointment) he contrasts with that of Tasmania, which sometimes tastes of the Antarctic it faces described by him as just perfection,—to a man, he means, who has spent a large portion of his life in a tropical hill country, where torrid heat is tempered by coolness due to altitudes. But even in Peru extreme altitude can produce cold as intense as arctic or antarctic blasts. One account runs.—

In all the lower regions of the country the climate is warm, but healthy; in the uplands, and on the highest plateaux, it is often inclement. Violent storms beat upon the plain of Titicaca and terrific tempests, accompanied with thunder and lightning, roll frequently around the table-lands of Pa-co; where, indeed, the climate is so cold, that but for the mines, which have attracted hither a numerous population, this region might have remained uninhabited.

The same as to cold may be said of Tasmania and its exceedingly rich mining regions which will yet enable it to rival what Peru was in the days of its glory. On soil and climate, natural productions and suitability for the culture of such products as coffee, tea, cacao and the like, our friend is an excellent authority. But he says nothing of the malaria, which is not likely all to have forsaken the jungles of South America, since the cure of the Countess of Chicheon, wife of the Spanish Viceroy, gave its name (mutilated by Linnæus) to the valuable fever bark which, native specially to Peru and Bolivia, has been, mainly by the enterprise of Ceylon planters placed within reach of the sick poor, instead of being the expensive luxury of the rich. Mr. Sinclair's prejudices against the native "Indians" (not a merely mutilated but an absolutely misappropriated name), he avows, were removed by an incident which is interesting as showing that "one touch of nature" in the shape of hospitality "makes the whole world kin." But it has yet to be proved that the Indians will prove to be good labourers on estates, or that labour otherwise is abundantly available. But granting that the reports brought up by the Ceylon trained spies of the land of promise are favourable on the points adverted to, we are reminded by the telegram just received of a fatal and devastating earthquake, that nature in America can in a moment exchange placid beauty for the most terribly destructive and relentlessly cruel letting loose of forces, which spare neither property nor life, but entomb human beings in the ruins of their abodes. Nature, in fact, is seized by recurring fits of anarchy, a characteristic which the volcanic Andes seem to have imparted to the races who dwell on their slopes or inhabit the plains at their base. Our correspondent gives a painful account of the effects of the war waged by Chile against Peru on the latter country, for which it is possible that Chile has just been subjected, by way of retribution to the unutterable horrors of civil war. The occurrence of similar horrors in Peru are not only possible, but, judging by the past, probable. In the strife of factions, equally reckless of principle, what would be the fate of foreign wealth invested in plantations and stores? Would either or both parties to civil strife hesitate to confiscate

to their own use capital or property? Such are a few of the reflections per contra to the paradisaical descriptions of our gifted correspondent which occur to us. We shall await the regular report, but at the moment we are inclined to think that Ceylon and other British possessions, even poor unprogressive Tasmania, have advantages of their own: a negative one in the absence of earthquakes natural or political.

THE DUTCH MARKET.

Amsterdam, August 13.

CINCHONA.—The cinchona bark sales, which will be held in Amsterdam on September 3, 1891, will consist of 2,686 bales and 190 cases, about 218 tons bark, among which from Government plantations, 278 bales 77 cases, about 29 tons; for private plantations, 2,403 bales 122 cases, about 217 tons. The bark is composed as follows:—*Druggists' bark*: *Succiruba* quills, 178 cases; broken quills and chips, 102 bales 6 cases; root, 42 bales. *Manufacturing bark*: Officially broken quills and chips, 20 cases; *L. dgeriana* quills, 3 cases; broken quills and chips, 1,565 bales; root, 643 bales; hybrid quills, 12 cases; broken quills and chips, 182 bales; root, 117 bales. Total, 2,686 bales 190 cases.—*Chemist and Druggist.*

BARK AND DRUG REPORT.

(From the *Chemist and Druggist.*)

LONDON, Aug. 22nd, 1891.

ANNATTO.—Eighty-three bags good dry velvety seed, from Ceylon, sold at 2½ per lb. today; another smaller, rather duller, realised 1½, per lb. Seventy-four bags of what may once have been Brazilian roll annatto (some of it was imported in 1869) were offered without reserve, but only one lot of old hard red annatto (1871 import) sold. It brought 8½ per lb.

CALUMBA.—Of 161 packages offered today, only 16 sold, without reserve, at 17s 6d per cwt. For ordinary brownish and slightly wormy root. Good washed sifted calumba was bought in at 5s per cwt. today.

CARDAMOM.—The supply at today's auctions was small—only 72 packages; but some parcels stand over until tomorrow. Prices are generally 2s to 3s per lb. advance. The following prices were paid:—Mangalore—Baccator, pale round medium, 2s 6d; small 2s per lb. (both are held for 3s 8d); split and speck, 1s 6d per lb. Ceylon—Mysore, bold pile round, 3s 5d; medium size, 2s 4d to 2s 5d; small to medium, pale long and thin mixed, 2s to 2s 1d; yellow mixed, 1s 10d to 1s 1d; small yellow and brown, partly split, 1s 5d to 1s 6d; rather better ditto, 1s 8d per lb. Ceylon—Malabar, small to medium, good plump yellow, 2s 3d to 2s 4d; very small round, 1s 3d to 1s 5d; split dull brown speck, 1s 6d per lb. Seeds sold very high, at 2s 2d per lb.

COCULUS INDICUS.—The price is still rising slowly. At today's sales, 20 bags realised 11s per cwt.

OILS (ESSENTIAL).—Citronella oil in tins is held for 11-16d per oz.

QUININE.—The market has declined further, and 101 per oz. was accepted for German bulk on the spot early in the week, since when about 100,000 oz. have changed hands at that figure. A sale of 10,000 oz. November-December is also reported, at 10½ per oz.

WHILE NEWS comes from the Wynaad that the coffee crop there is going to be a bumper one we are also told that gold is disappointing the searchers. Every one who is any one in geological circles admits that there are rich auriferous deposits in the Wynaad tract, but the amount of capital required to properly develop the gold industry has never yet been utilised there, and bad results are the consequences. Some of the mines there are doing so indifferently that large numbers of hands have been turned adrift to swell the vast and discontented ranks of the unemployed. Some very hopeful planters tell us the El Dorada days of coffee planting are coming back to Wynaad. "Oh I let it be a con."—*Malabar Spectator.*

"DESICCATED COCONUT."

Very few in the island have an adequate idea of the extent to which the industry in desiccated coconut has been developed in our midst. A short time ago we referred to the increasing exports; and since then the Chamber of Commerce has recognised the importance of this latest prepared or manufactured product by including it in the list of staple exports in their weekly table. Our reference to the industry as carried on in the Veyangoda establishment of the Orient Produce Company, Limited, Dematagoda Mills, &c., has brought us a letter from a London merchant interested in the matter, who roundly declares that, like so many other branches of enterprise in Ceylon of recent years, the preparation of desiccated coconut is certain ere long to be overdone. "We are alarmed," he writes, "at the prospect of so many going into the manufacture, knowing that it must mean loss to all. The consumption of such an article is, as you might suppose, not unlimited, and any considerable increase in what is now being shipped would exceed the requirements of all the outlets yet discovered. If so many are really starting the manufacture, as stated in your issue, the production will be so much in excess of requirements that the fight for survival must end in the ruin of some of the competitors." This is a point on which we are unable to express an opinion, seeing that our pessimistic correspondent has given us no clue to the market demand or to the present rate of consumption as compared with what it was some years ago. But this much is certain—that, for good or evil, the preparation and export of desiccated coconut from Ceylon has increased, is increasing, and is bound still further to increase for some time to come. A great impetus has been given to the preparation, we understand, through the discovery that Mr. John Brown's patent "Desiccator"—this well known tea-drying machine—afforded with a little adaptation the very best means of drying and desiccating the sliced coconut kernels. The process altogether is kept as secret as possible; but it is understood that the first step is to slice up the kernels, and for this purpose there seems to be a machiuo in use (previously used for slicing the kernels preparatory to grinding in oil-making) with an ingenious arrangement of knives that cut up the coconut kernels very quickly. Then comes the drying; and for this purpose, as we have said, the desiccators are found so suitable that in one mill some half-dozen are said to be at work; while, as agents, the Colombo Commercial Company are favoured with not a few further orders. To the older establishments at Veyangoda and Dematagoda, there have lately been added arrangements at Kollupitiya Mills (Messrs. Lee, Hedges & Co.) and at Negombo (Mr. Akbar's) for the preparation of desiccated coconut. On the other hand, to counter-balance the effect of this news, we are able to inform our London mercantile friend that a demand for the new product in Australia is springing up. We had an advertisement the other day from a large Melbourne firm, intended to arrange for a purchasing agency for this article. Though to some extent classed as "confectionery," desiccated coconut must surely, to a considerable extent, be regarded as a "food product," and as such we have some reason to look for a wide and expanding demand such as we trust, may ensure a profitable market for all that Ceylon may turn out for many years to come. The exports so far recorded in the Chamber's table are as follows:—

From 22nd June to 7th Sept. 1891—559,528 lb.

CACAO IN RANGOON.—The *Rangoon Gazette* of Aug. 28th says:—We have just seen a large cocoa pod, which Dr. Stephens has received from Ceylon from his father's properties. Dr. Stephens presented the Agri-Horticultural Gardens with a fine cocoa plant, over five feet high, but this unfortunately died and he has now obtained seed for the Gardens, and will be happy to obtain some for anyone who wishes to grow cocoa. He has also some coffee and tea plants, which he will give to anyone who will grow them carefully. Cocoa requires little cultivation and the trees are decidedly ornamental.

TEA FOR HORSES.—A correspondent sends us the following from the *Graphic*:—

Afternoon tea has become such an institution with English people that even their horses are to adopt the habit. Competent authorities assert that tea is the best restorative for horses, the animals being quite revived after a hard day's work by a drink of weak tea with milk and sugar.

Our correspondent writes regarding this above:—"Oh ye gods and little fishes! It actually makes me convulsed with happy thoughts of the near future. Take courage now, oh ye Knights of the Tea Bush; don't ye mind the croaking brokers in Mincing Lane. Send your muck and flood the market! Horse troughs to your rescue!!! It won't be a bad idea to agitate for a horse census in the United Kingdom; we might start one in Ceylon too, not excluding jaw-bones! Eh! Mr. Editor?"

TURKISH LIQUORICE.—The British Consul at Bussorah, in an interesting report on the growth of the liquorice plant on the banks of the Tigris and Euphrates says that these great rivers in the part where the root is found flow through flat, treeless prairies of uncultivated and nearly uninhabited land. For three months of the year hot winds blow, and the temperature reaches 104deg. For six months the climate is moderate and salubrious, and for three months bleak and wintry, the thermometer going down to 30deg. at night. The liquorice plant is a small shrub, with light foliage, growing to about three feet high, where its roots can reach the water. It grows without any cultivation. No lands are leased for the purpose, and no objection is made to its being collected. It is found in abundance from Ctesiphon, ten miles from Bagdad down to Kut-ul-Anara, half way between Bussorah and Bagdad. It grows on red-earth soil, and also on light almost sandy soil, where the wood is best, provided, it has plenty of water, and the ground is not more than 50 yards from the actual river or stream. Only one firm works it in Bagdad, and it is well known that the business is a prosperous one. The wood, after being once dug up and cut grows again better afterwards. The time of collecting is, generally speaking, during the winter, but it is possible all the year round. The root when dug is full of water, and must be allowed to dry, a process which takes the best part of a year, especially in hot weather. It is then sown or cut into small pieces six inches to a foot long. The good and sound pieces are kept, and the rotten ones are used for firewood. It is then shipped in native river boats to Bussorah whence it is shipped in pressed bales to London, and again from there to America, where it is used largely in the manufacture of tobacco. The Consul thinks the trade is capable of expansion. The demand in America is great, and shipments are easily disposed of. After sorting there still remains some useless wood in the bales, perhaps 7 per cent. From figures supplied by the Bagdad firm engaged in the business, it seems that this total net cost of a ton of liquorice root laid down in London is about £4.—*London Times*.

THE AMERICAN CEYLON TEA COMPANY.

The letter from Mr. Elwood May to Mr. Leake of which our London correspondent has sent us an abstract contained intelligence which will doubtless be welcomed by every member of our planting community. For it will be generally acknowledged, we believe, that our present production of tea promises to necessitate the opening out of fresh markets as rapidly as may be possible. The low rates now obtainable for it in Mining Lane seem to evidence that at the present time the supply is at least fully equal to the demand for home consumption; and there seems to be no guarantee that, with fresh fields coming into bearing, we may not shortly pass beyond it.

Sir Arthur Birch, who is prominently associated with our tea planting industry, is reported as having said that this need for new markets is becoming an urgent one; and we are disposed to think that there can be found few who are likely to disagree with that view of our former Colonial Secretary. Reliance has for some time past been placed upon America's furnishing us with this new opening for our tea; and the intelligence we have now received seems to promise that the reliance is not likely to prove unfounded. Ever since Mr. Grinlinton paid his visit to the States and opened out negotiations with Mr. May, and more especially since the latter gentleman visited England and placed himself in communication with the Ceylon Association in London, we have expected that we should soon hear of some great step in advance being achieved. This expectation seems to be now in a fair way towards realization. Not only as newspaper proprietors ourselves, but as part of the general public experienced in such matters, we have acknowledged how greatly success in the introduction of a new article of trade must be dependent upon liberal advertising. In a country like America this is even more than elsewhere a fact that cannot be gainsaid; and Mr. May seems to have been more than commonly fortunate in securing a contract which will enable this advertising to be done without necessitating any financial outlay either by the planters of Ceylon or by those who are so energetically exerting themselves on their behalf in America.

The *imprimatur* sought by Mr. May from our Planters' Association and from our representative body in London seems to have been productive of the happiest effect, and the result obtained has more than justified Mr. May's contention that the securing of that *imprimatur* for his company would enable him to "go ahead," as the Yankees say, with rapid strides. As we understand what our London correspondent has communicated to us of what Mr. May had written, the compliance with the requests he made that his Company should receive official acknowledgment has enabled him to secure the co-operation of men of very high social and financial standing in New York. The names of these parties, although given by Mr. May, have been withheld from us until it is known if that gentleman consented to their publication. But the main thing reported is that the proprietor of several very influential American papers and periodicals has consented to enter into a contract to do 50,000 dollars' worth of advertising of the American Ceylon Tea Company, he to receive payment in the stock of that Company. Now 50,000 dollars—or, roundly speaking, £10,000 sterling—of expenditure on advertising cannot fail to do much to advance the interests of the American Association dealing with pure Ceylon tea, and were this advantage the limit of good things promised, we

should have much to congratulate ourselves upon.

But this is not the limit which we may hope to see reached. The newspaper proprietor referred to has secured the privilege of extending the operation, should he see fit to do so, to the extent of 200,000 dollars or £40,000. Indeed, he has expressed himself as most desirous to extend his promise to that extent, but declines to bind himself to it in the fear lest, should he die before he could carry it out, he would be subjecting his heirs to a very large liability with which he does not think it fair to charge them. This, we can all see, is a perfectly good reason why he should decline to bind himself to the larger operation. It is, however, perfectly understood that, if his life be spared, Ceylon tea will be advertised throughout the United States to this amount of £40,000, without imposing the least charge upon our representative company in America. We need hardly point out—nor could we exaggerate—the advantages likely thus to be secured. No wonder that Mr. May has written jubilantly on the prospect before him, or that he expects in consequence soon to seek the execution of large orders for our tea and so open up fully that new market which the circumstances of the time render us so desirous of securing. If, further, Sir Arthur Birch and Sir William Gregory may be willing to afford to Mr. May the *agis* of their names, the latter regards his position and prospects as being most fully assured. We trust that both Sir William and Sir Arthur, in view of the interest taken by them in Ceylon, will be willing to grant the concession sought of them by Mr. May.

MR. MAY AND THE CHICAGO EXHIBITION;
ADVERTISING OF CEYLON TEA IN AMERICA;
SIR ARTHUR BIRCH AND
NEW MARKETS FOR CEYLON TEA;
ADULTERATION OF COFFEE.

LONDON, Aug. 21.

A letter received during the present week by Mr. Leake from Mr. Elwood May contains information of a kind which we feel will be very welcome to you all. This letter is a private one, so it is not permissible for me to give you its text in full; nor, until Mr. May's consent be obtained, to quote the names of the several parties whose conjoint action with himself he refers. This letter opens with the statement that he had wired to Ceylon "Rutherford's proposals accepted." This of course refers to those based upon the application made by Mr. May for aid with regard to the Chicago Exhibition. At last we presume here that it does so. The letter, which is dated from New York on the 7th August, then goes on to say that the recognition of his enterprise by the Ceylon Planters' Association and that of the Ceylon Association in London had enabled him to obtain promises of active support by several gentlemen of high social and financial standing in New York. But beyond this Mr. May reports that he has been enabled to conclude a most favourable contract for advertising his company with a gentleman who is the proprietor of several important newspapers and periodicals.

This contract binds the contractor to advertise the company to the value of 50,000 dollars, stock of the Company to be accepted as payment. That is as far as the contract extends on the side of the contractor. But further than this, and on the side of the company, it is conceded that, should the contractor see fit to do so, he can at his option extend the terms of the contract to 200,000 dollars, accepting stock of the Company to that amount

in payment. The contractor declines to pledge himself on his side to carry out the agreement to that extent, because, as he has very justly remarked, to do so would, in the event of his death occurring, too heavily burden his heirs. He has however stated that he is hopeful of being able to carry out the scheme to the larger amount should his life be spared. You will, therefore, see that a very great step in advance has been made towards pushing the sale of Ceylon tea in America. "Advertising," they say, "is the soul of trade," and too many proofs of the correctness of this saying come under our own observation to admit of its being doubted. And this end, under the arrangements concluded as above detailed, will be gained without its being necessary for the Company to advance a single dollar in cash. The contractor, of course, is imbued with the belief that he will be able to place the stock among his friends at a profitable rate, and Mr May augurs from this important arrangement that he will soon be able to extend the sale of Ceylon tea in a most considerable degree. Knowing what we do of Mr. May, and of the energy with which he works, we here entertain very little doubt what he now anticipates will shortly be realised.

The contractor believes that by the method he proposes he will be able to distribute the shares of the Company, partly for cash and partly in stock, among fully 1,500 of the leading newspaper proprietors of the United States, each of whom will then have a direct interest in furthering the development of the sale of Ceylon tea by the Company. Mr. May's letter proceeds to say that it would be an invaluable thing for him if he could succeed in obtaining Sir William Gregory's and Sir Arthur Birch's names as vice presidents of his Company. He told Mr. Leake, when in England, that if he could get "your aristocracy" to lend their names to his scheme it would ensure him success. Well, we can hardly rank the names of the two gentlemen above indicated among those of the British aristocracy, but no doubt even simple knight-hood goes some to a great extent among our American cousins. We know that Sir Arthur Birch has shown great interest in Mr. May's scheme, that gentleman, as you were informed by me, having brought with him on the occasion of his late visit to England a very strong letter of introduction to Sir Arthur, who, Mr. May further informs us, has since he had returned to New York written him very warm wishes for his success. If both your former Governor and your former Colonial Secretary will consent, in view of the great impetus it would give to the sale of Ceylon tea in America, to permit the use of their names as suggested by Mr. May, it would no doubt greatly aid the latter in his enterprise.

No one, we are told, recognises more fully than does Sir Arthur Birch the pressing necessity that there is for opening up new markets for Ceylon tea, and that with all possible speed. He is, we hear, himself connected in a large degree with your leading industry, and he is certain, therefore, to closely watch the markets. He cannot have failed to notice how seriously the competition for your teas has fallen off of late. All those with whom I have commenced on the subject admit this to be the case, and attribute it to the imports overreaching the present demand. The advisability, therefore, of giving Mr. May the fullest supports possible must be freely recognised by Sir Arthur Birch, and possibly Sir William Gregory may also recognise that desirability. But even should those gentlemen hesitate to grant what Mr. May desires of them, the news I have been able to give you cannot but be pleasurable to the whole of your readers.

Below is given an extract from the *Times* summarizing a most interesting article in the *Kew Bulletin* with respect to the adulteration of coffee in the United States. Of course we have often heard of the artificial beans to which reference is made, but it is—at all events to myself—quite a novelty to learn to what a large extent the manufacture and use of them has extended. The matter is not now of the same importance to your planters as it would have been before the failure of coffee in your island, but it cannot even now be said to be wholly a matter of unconcern to some of them that this method of adulteration should be checked.

SPURIOUS COFFEE.—The current issue of the *Kew Bulletin* contains some information respecting the manufacture of artificial coffee beans, an industry which appears to have assumed some importance in the United States. As far back as 1860 the late Dr. Lindley presented to Kew carefully-modelled artificial beans, intended for mixing with the genuine beans, and which were supposed to be made from finely-powdered chicory. The American beans are supposed to be composed of rye flour, glucose and water, and are prepared to resemble in size and colour a moderately good sample of roasted coffee beans, and by the introduction of a few genuine beans they acquire the aroma of true coffee. The modeling is sufficiently good to deceive the public, although if critically examined differences appear. But "the general characteristics are those of fair coffee with small and somewhat broken beans." It is said that 20 per cent of the coffee sold to consumers in the United States is artificial. The spurious beans can be made at a cost of £6 per 1,000lb. and the latter when mixed with 50lb. of pure coffee finds a ready sale, and yields a profit of cent. per cent. "Coffee substitutes" are also largely manufactured in the United States, one firm alone producing 10,000lb. a week. The article is sold by the manufacturer as "coffee substitute," not as coffee, and therefore he violates no law against adulteration; but the retailers throughout New England and the Central States who purchase it by the barrel either sell it as genuine coffee or mix it with coffee which is genuine. The production of artificial coffee has also received some attention in Germany. An Imperial decree has forbidden the manufacture and sale of machines for producing the artificial beans. These latter were recently extensively advertised in German newspapers and attracted the attention of the Government. The beans are intended to mix with genuine coffee, and not to produce a beverage which might act as a substitute for coffee. The British Embassy in Berlin found it impossible to obtain any of these spurious beans for Kew, as the machines for making them have been confiscated.—*London Cor.*

THE CULTIVATION of the Yokohama and Hong Kong bamboos is to be tried in various parts of the Madras Presidency, and arrangements have been made to import a large quantity of seed for

A QUANTITY of CEYLON TEA made up in $\frac{1}{2}$ lb. packets is to be distributed free in Perak. The duty has been entrusted to Mr. Hanson by the Tea Fund committee of the Ceylon Planters' Association, who are endeavouring with commendable energy to push the sale of Ceylon tea in all parts of the world.—*Pinang Gazette.*

ALLEGED NEW TEA PEST.—A former tea planter now on the Nilgiris writes to a local contemporary about an alleged new disease in tea which, although affecting the branches and not the leaves, he ventures to think must be the "origin" of the coffee leaf disease, *Hemilia vastatrix*! The statements are vague and unscientific; and the object seems to be to bring an alleged remedy into notice. That a few branches of tea bushes should be affected with "insidious defunction" is neither wonderful nor alarming.

OUR FISHERMEN AND FISHERIES.

Probably few among us have given much thought to our fishermen and fisheries, and to the important place assigned to fish as an article of food in South India, especially by dwellers in the towns and villages along the coast. It is only when the fish world is affected by some epidemic, as was reported to be the case several years ago, and fish as an article of diet is prescribed for a brief space, that we realise the value of it as human food. Most of us know more of fishermen than fisheries, for of them some statistics are available, but of our fisheries, Government has hitherto taken but little note, and we search the "Madras Manual" in vain for some reliable information concerning them. The fishing castes number about a million persons in all, but those who live inland, far removed from sea and river, follow the occupation of hunters, and, since they cannot destroy the creatures of the water, live by destroying the creatures of the land. The fishermen are known by many names, and their kingdom has been invaded by other castes, who also seek to seize the treasures of the sea, but the Pattinavar are the original fishermen, the real Simon Pure. They are of an ancient Dravidian stock, and represent one of the most ancient types of civilization to be found among the dwellers on the plains. Compared with the Pattinavar, the ryot is a civilised and polished gentleman, and his occupation and implements of husbandry represent a civilization many centuries in advance of that of the fisherman. The Pattinavar, as fishers and hunters, exhibit to us man in a state of mere animalism, preying upon other creatures, and possessing but little more genius of an inventive or mechanical kind than is to be found among birds or spiders. Even after the lapse of thousands of years, this is still true of them; they appear to have made hardly any advance, and their houses, clothing and equipment for their toil are generally as primitive as they were when the Aryans crossed the Vindhya Mountains. The houses are leaf huts, consisting of a circular mud wall some two feet high, on which a palmyra framework with a covering of palmyra leaves serves as a roof. To the hut there are no windows, but only an opening for ingress and egress, which serves as a door. The boat of the fisherman is the *kattu maram*, which properly consists of five pieces of wood fitted close together and tied at the ends with rope made of the fibre of the coconut tree. On this raft they are perfectly at home, and guide it where they will by paddling, and occasionally by a brown sail of rough canvas. They make and mend their own nets, and for this work their implements are of the simplest.

The work of the fishermen is hard enough, yet on these shores they are not exposed to such risks as beset the fisher in Western and North seas, and we rarely hear of deaths by drowning, or of such calamities as happen, for example, to those engaged in herring fishing. Probably nowhere in the wide world can better swimmers be found than our India fishermen: they take to the water as naturally as ducks and from their childhood are accustomed to go to sea on the *kattu maram*. The income of the fishermen is generally sufficient for their maintenance, and in the neighbourhood of Madras and other large towns is abundant, and, if they were accustomed to cultivate habits of temperance and thrift, would amply suffice to secure for them many comforts in addition to the necessaries of life. But of all the Hindu castes, there are no more

abject slaves to drink than they. Their degradation could hardly be more complete than it is, and toddy-drinking is the cause of it all. The Shanar is their destroyer, and quite recently when in one village there were signs that a number of men were making an attempt at total abstinence (for to the Hindu low castes moderation in drinking is impossible), the Shanar visited the hute of the fishermen, and appealed to them not to forsake him, promising to supply them gratis when they should come again. It is needless to say that Pattinavar virtue is not proof against an offer like this, viz., to be made drunk free of cost. By way of training the fisher-children, in drinking habits, the fathers bring them as mere infants to the toddy-shop, and they each receive free of cost from the Shanar a small draught of toddy, or if a small tin-pot of regulation size be brought, it is duly filled for the child at home. Thus the continued ruin of the caste is secured, and life is shorn of all comfort. The fisherwomen are for the most part coarse and unattractive, and grow prematurely old. It is a rare thing to see any of them really clean and decently clad: their life is without adornment and full of hard work. Surely the fish-girl from whom Vyasa, the Veda-maker, sprang was better looking than Pattinavar women are now-a-days. Vyasa at least was better educated than are the children of our modern fishers, for we find among them no schools, nor influences of any kind calculated to improve them and secure their social advancement. And though they reckon Kanniyanma as their deity, the toddy-shop may be said to be their temple. It is impossible to avoid the regret, that a caste so ancient, useful and hard working should be so completely unable to rise to a better social condition. Polygamy is common among them, and married life by no means all that it should be, and in the speech both of men and women, and in the games played by their children, we hear the most indecent expressions which the vernacular can supply. If the headmen of the caste were intelligent and worthy enough, they should pass a law for the Pattinavar compelling the education of all their children, and in a few years a wonderful change for the better should be apparent. They have the power to do this, but whether they have the public spirit and the requisite courage is another matter.

Like our fishermen, our India fisheries receive but scant attention from Government. Statistics of fisheries are nowhere very complete, but incomplete as they are, they suffice to impress on us the fact that the sea makes large contribution to the food-supply of the world. In India, where we are continually experiencing difficulty in obtaining a sufficient food-supply, it behoves Government to give special attention to every source from whence contributions to it may be obtained. In a city like Madras the fisheries contribute enormously to the food-supply, as may be discovered by a visit to the local Billingsgate, and an abundant supply of fish tends to cheapen fish as an article of diet. Though it may be said that there are no signs of famine in the sea, and that the fish-supply is by no means scanty, it is worth considering whether the supply cannot be made far more abundant, and the price of food thereby considerably cheapened. We have no doubt but that this can be done. Among the non-European population, it may be said that nearly all kinds of fish, and they are very many, are eagerly consumed, and besides those which are eaten fresh, immense quantities of salt-fish are also used. These find their way

among the villages and serve to improve the dietary of the poorest classes. In the absence of statistics, we may form some idea of the extensive trade in salted and dried fish, which is carried on in the Pulo Idoney, by a reference to the report of the Salt Department. It will there be seen that the quantity of salt used for this purpose is enormous, and that this trade in dried fish is an increasing one. It is well known that the flesh of fishes differs in different seasons of the year, and that there are times, as in the spawning season, when they are not very fit for human food. But in India, among our fishermen, no notice whatever is taken of this fact, they catch all they can, great or small, and at every season of the year. We are of opinion that among the non-European community, not a little ill-health is due to the want of attention here. The destruction of spawn in our estuaries is common; we have ourselves seen men day after day capturing them by thousands for their food, and have found remonstrance with them of no avail. As a result of this, added to the fact that multitudes of fishes are caught long before they are half-grown, the fish-supply is not nearly so plentiful as it might be, and the matter is of sufficient importance to justify a little Government interference. For our fish-supply, as an article of food for poor, is worthy of all possible attention. In the country the right of catching the fish in tanks is usually sold by auction, and purchased by the caste villagers for a trifling sum. An instance occurs to us of a village in the Chingleput district where, after purchasing for four rupees the right in question, as they know how to do, the caste villagers immediately resold it for nearly a hundred rupees. If Government were to throw such tanks open to the poor, that they might increase the food supply, this would be a great boon, and the jobbery to which we have referred would be brought to an end. At any rate, we think that some cognizance should be taken of our South Indian fisheries, which are of such importance to the people as a source of food, and if something can be done to regulate them, so that they may become more profitable and yield a still more abundant supply, Government will have its reward.—*Madras Times*.

NOTES ON PRODUCE AND FINANCE.

INCREASED CONSUMPTION OF TEA.—We gave some figures in our last issue which showed the increased consumption of tea since the reduction of the duty. The Commissioners of Customs point out that the extent of the loss which the Revenue has sustained by the reduction in the duty of 2d per lb., when compared with the preceding year's receipts, is not so great as had been anticipated, the increase of consumption having been very marked. The gross revenue from tea in 1889-90 was £4,490,695. Last year it was £3,416,802, an actual loss of £1,073,893. The quantity of tea on which duty was paid in 1889-90 was 179,620,000 lb. In the year ending March last the quantity was 202,633,000 lb., an increase of 23,013,000 lb. It is curious to note that in 1835, when the duty ranged from 1s 6d to 3s, according to the quality of the article, the amount netted by the Revenue from this source stood almost exactly at the same figure as at the present moment, when all kinds of tea pay only 4d.

THE AMERICAN TEA MARKET.—It is pointed out by a Philadelphia correspondent, for the benefit of those interested in the American tea market, that the taste of consumers in the United States is fickle. Twenty years ago the rage in the States was entirely for Foochows; then basket-fired Japans and China greens followed in order, nothing else being in demand

for a time; to be again succeeded by Amoy and eventually by Formosas. At the present time the popular taste seems to be returning to its first love, Foochow oolongs, to the prejudice of Amoy and Formosa. The changes appear to occur exactly about five years apart. We trust that Indian and Ceylon teas will have their turn.

THE RIVALRY OF INDIAN AND CEYLON TEA.—In his report on the trade of India, Mr. O'Connor calls attention to the competition of Indian and Ceylon in the tea market, or rather he points out figures which indicate this position. He says that "while the United Kingdom took from India in 1890 over a hundred million pounds of tea and only seventy-four millions from China, it had also taken forty-two-and-a-half million pounds from Ceylon, a remarkably large quantity considering the recent commencement of tea cultivation in that island. Ceylon, Mr. O'Connor points out, has certainly greater advantages in its greater nearness to England and to Australia than Calcutta, and the consequent smaller freight that has to be paid, in the case of proximity of the tea gardens to the port of shipment, in the abundant and cheap labour supplied to it from the adjacent parts of Southern India, in climate conditions, and in the excellent quality of most of the tea produced." This is all true enough, and tea planters are quite aware of it. The rivalry between India and Ceylon is, however, a friendly one. The Indian idea being to keep China tea out of the market as much as possible.

TEA SHARES.—The following letter signed Z. appeared in the *Financial News* of yesterday's date:—"Your useful and accurate article on the position of the tea companies has attracted a good deal of attention, and I hope you will allow a little discussion on the subject, in the interests of those who are already concerned as proprietors, as well as of those who would like to have a pecuniary interest in the business of tea production. There is no question as to the highly profitable nature of the industry; it is really much more so than the figures of the few companies quoted show, because a large proportion of the best estates, though worked by companies whose shares can be obtained by those in the trade through private treaty, are not known in the general market. The industry is also subject to much less risk than is generally supposed; failure of crops over any but a most limited area is unknown; cultivation and manufacture have now almost reached the level of a science; while the uncertainty attaching to value which existed in the early days of Indian teas as an article of commerce is a thing of the past, seeing that it has taken the leading position in the market, almost extinguishing the trade in China tea, as far as this country is concerned, and has quite outstripped in point of quality its only serious rival, Ceylon.* This being so, the question arises why Indian tea companies attract so little attention from the investing public, and, with the exception of the *Financial News*, from the financial Press. Is it not because those who manage the companies impart so little information about the course of the year's operations? Some of them only communicate with their shareholders once a year; many only twice a year, while those who issue monthly returns of the quantity produced give no information respecting the realisation of the crop. Investors do not like to be kept in the dark like this, and the reticence of managers is the more unaccountable inasmuch as the industry is carried on in the light of day, the crops grown above ground, and mostly sold in the public auction room, while for honourable and business-like management they can challenge comparison with any industrial undertaking. Another drawback seems to be the share value ranging from £5 to £20, denominations disliked by the small investor, who calls for a £1 share fully paid. But possibly the chief obstacle to a free market in the shares lies in the fact that there are too many small companies, each with separate management; their

* Ceylon plantors will certainly not admit this.—*Ed. T. A.*

operations confined to a limited area of land, and with no Stock Exchange quotation for the shares. The remedy for this is obvious—viz., amalgamation, with its consequent reduction of cost and equalisation of annual profit, through the risk being distributed over a wider area. The history of the Jokai Company of Assam, a combination of numerous estates which used to be separately worked, proves how successful this policy is. The need for some such measures being taken must be impressed upon the most conservative of managers, as they witness the pioneers and founders of the industry passing away one by one, and discover how difficult it is for trustees and executors to realise their holdings when necessary, except at a 'giving away price,' for the sole reason, as our stockbrokers inform us, that 'nobody knows anything about tea shares.'

OUR LAST WEEK'S TEA SALES.—Indian tea is coming forward more freely, says the *Produce Markets' Review*, & *propos* of last week's sales, and the public sales will continue to be held three days a week instead of two, as has been the case during the past few months. The quantity shipped from Calcutta is about 4,000,000 lb in excess of the same period last year, and the market therefore will now be liberally supplied. The arrivals so far have not been equal to the average quantities of past seasons, a large proportion of the tea, including some of the better known gardens, being poor, but prices having fallen to a comparatively low level, these kinds have gone freely into consumption. The scarcity of better tea is shown by the active bidding for the small quantity offered; the prices realised must be satisfactory to importers, and should encourage them to furnish this market with a larger proportion of higher grade tea than they have sent this season. At the public sales 19,389 packages were brought forward, and only 2,120 were withdrawn, which have mainly been disposed of since. The demand was fairly active, the latter sales showing greater strength, and prices generally were rather firmer, a few really fine teas fetching extreme rates. The sales of Ceylon teas have been extremely large, but the market has firmly withstood the unusual pressure, and prices have on the average been higher than those of last week. There has been a decline in the commonest grades at from 6½d. to 7½d., and the value now offering is such as has not been seen for the last three years. This fact has been generally recognised by the trade, and a large business has resulted. The quality of the late imports has shown a slight improvement, and with a diminution in the excessive supplies, this should tend to enhance values still further.

A "GOLDEN TIP" SALE.—A small parcel of Golden Tip from Ceylon marked "Maha Ketiya" was this week knocked down at 35 guineas per lb. Although the Lane has ceased to take any interest in these fancy sales, they continue to serve as an advertisement both for Ceylon tea and the purchaser of the expensive packages.—*H. and C. Mail*, Aug. 28th.

THE BRITISH NORTH BORNEO Co. seems to have fallen on evil days, to judge by the report presented at the half-yearly meeting held on 31st Aug., the proceedings of which, contained in the *London Times* received by the German mail steamer will be found elsewhere. The chairman, it will be seen, laid the chief blame of the unfavourable condition of the Company on the late manager, who has been dismissed. The low price of tobacco was also another cause of loss. Some of the shareholders, expressed their opinion of the directors' conduct pretty freely; and though the report and accounts were ultimately received, it was only with the understanding that fresh accounts were to be prepared and presented at a meeting to be held in a few months' time. It is to be hoped that Mr. Henry Walker, who has been sent out in connection with the present crisis, will be able to give a more hopeful report.

PROFITABLE USES OF THE MANGO CROP.

The following is extracted from a report of Mr. Shelton presented to the Queensland Department of Agriculture, and reprinted in the proceedings of the Agri-Horticultural Society of Burma.

Recently, in various shapes the question has been put by fruit-growers living in different sections of the colony: How can the great mango crop of the present season be utilised by preserving or otherwise, so as to be made available throughout the greater portion of the year? To meet this and like inquiries, Mrs. Shelton and myself have undertaken a considerable number of experiments having for their object to preserve the fruit with as much as possible of the original mango characteristics of texture and flavour. Our experiments covered canning and the making of marmalade and jelly.

The fruits furnished by Mr. Edgar, of Rockhampton, although differing greatly in minor particulars, are roughly divisible into two classes—those large growing varieties having dark green skins, light cream-coloured flesh, and a distinct and pronounced acid flavour with a minimum of the turpentine taste; and those varying greatly in size, form, and colouring, but all having deep golden coloured flesh, which in ripe specimens is very sweet and soft. Undoubtedly the former are as valuable for cooking and all forms of preserves as the latter are for use in the raw state—i.e., eating from the hand. Our experiments show, too, that best results from cooking are always obtained with fruit that is full grown, but firm and not over ripe. In making marmalade and jelly, a mixture of the two sorts in equal portions gave very satisfactory results. The large, light-fleshed, acid sorts gave a marmalade hardly distinguishable from that made from the best apples. The addition of the golden-fleshed varieties proved useful in giving to the product a very distinct and agreeable mango flavour.

After peeling, the fruit is separated from the stones by slicing into pieces of convenient size; these should be stewed for a few minutes only, before pouring into the cans, in syrup strong or weak in sugar to suit the taste. Or the fruit may be cooked in the can with syrup as before. There may be a difference of opinion as to the palatableness of canned mangos. A considerable number of those persons who have tasted the results of our work have pronounced the canned fruit excellent, while others have declared their indifference to it. A like diversity of opinion, we note, holds respecting the raw fruit, particularly with those unaccustomed to its peculiar flavour. Mangos stewed in the form of a sauce will be found a welcome addition to any dinner table. "As good as stewed peaches," we have heard them pronounce.

Webster defines marmalade as "preserve or confection made of the pulp of any of the firmer fruits boiled with sugar, and usually evaporated so as to take the form of a mould." Nearly in this sense the word "marmalade" is used in this essay. Peel and slice the mango, cutting close to the stone, and cook, using plenty of water. Boil until the fruit is thoroughly disintegrated, when the pulp should be run through the colander with the purpose of extracting the "wool." Sugar should now be added to suit the taste (about ½ lb. to the pint of pulp), and the mass boiled until clear, when it would be poured into the moulds or jars in which it is to be kept. This marmalade is of a rich golden yellow colour, it retains the form of the mould perfectly, and its seems in all respects to satisfy the most exacting taste. In the absence of the experience necessary to test the keeping qualities of mango marmalade, it would be part of wisdom to seal the jars designed for future use with hot wax, or better yet, with a plug of cotton wool.

For jelly, prepare the mangoes by slicing as for marmalade, boil the fruit with water, prolonging the boiling only to the extent of extracting the juices. Great care should be taken in boiling as the mango rapidly "boils to pieces," in which case it is impossible to make satisfactory jelly. Pour off the juice, strain

and boil down to a jelly—an operation that occupies only a few moments, as the mangoe is rich in gelatinous materials; the pulp remaining after jelly has been removed may be used to advantage in making marmalade. In the amount of sugar used in making jelly, the housekeeper is safe in following old practices in this respect with other fruits. It is impossible to give exact rules in all the operations connected with working up this fruit. In general it will be well to use, in boiling, water somewhat in excess, and as the mangoe "cooks" readily, constant watchfulness is needed to prevent burning.

To show something of what is possible in the way of results with this fruit, I may say that in our experiments that on good-sized mangoes gave one peck of jelly and five quarts of marmalade. This certainly must be counted a very favourable, not to say remarkable, result.

It is clear to me that there are great possibilities in connection with the Queensland mango crop. If put upon the market in attractive form in the shape of jelly and marmalade, it would be certain to come into almost instant popularity; and that it might be manufactured and sold at a handsome profit is apparent from the figures here given.—*Rangoon Gazette*.

◆

**MANA GRASS BOARD FOR TEA BOXES
A SUCCESS—A NEW INDUSTRY FOR
CEYLON—STANLEY-WRIGHTSON SYNDI-
CATE AND MR. ELWOOD MAY—
PROSECUTION OF TEA ADUL-
TERATORS.**

LONDON, Aug. 28.

At length, and during the present week, it has been possible for me to see the square tea boxes moulded, as regards the sides, in one single piece from the mana grass pulp. They were exceedingly strong and serviceable looking, and it is intended, we hear, to adopt the method of putting in the heads and bottom pieces followed by the Stanley-Wrightson Syndicate, though this, to my mind, may even yet be considerably simplified. The board of which the boxes are composed is exceedingly stout and hard, and even my weight—which is by no means inconsiderable—had no effect towards altering their shape. Dr. Norman Evans himself brought these boxes to the office of the Stanley-Wrightson Syndicate, and expressed his full satisfaction with them.

It may be as well to give you the following extract from his report made to the syndicate above-mentioned on the course of manufacture that he watched, and on its result. He writes, under date of August 25th:—"The grass was boiled for eight hours with a pressure of forty pounds (of steam) and fifteen per cent. of lime. On visiting the mill on the morning of August 6th, I found the grass properly boiled. We were able to beat it in the engine for four hours with far less trouble than we had ever before had. To 200 lb. of the dry grass was added forty pounds of rough paper, which gave 150 lb. of dried board and barrels. The stuff ran well in the machine, giving good thick boards and barrels (see specimens) which dried without blistering or splitting. I think that this experiment conclusively shows that it is possible, with the addition of a comparatively small percentage of old paper, to manufacture good solid boards out of mana grass. (Signed) P. NORMAN EVANS."

Success having so far attended the repeated trials made with this material, the course to be followed to utilize their results has now to be considered. Undue haste might be attended by disappointment, but, we have it said that the Universal Barrel Company intends negotiating with the Stanley-

Wrightson Syndicate for the purchase of its Ceylon patent, and that it has already entered into communication with a gentleman in Colombo with the object of arranging for working that patent in the island. It would be premature to add anything to this statement; but we hope that it may prove to be the prelude to the successful introduction of the manufacture of these tea boxes in some locality adjacent to your tea estates. It may perhaps be usefully added that, although quite new, the boxes had no appreciable smell.

Further with reference to the proceedings of the Stanley-Wrightson Syndicate it may be written you that Mr. Elwood May proposes to purchase their American patent and to manufacture boxes locally, which, after that amount of embellishment that American taste seems to demand, will be used to distribute the tea to their customers. A large amount of their tea, however, the American Ceylon Tea Company proposes to send out from their stores in highly ornamental packets. Specimens of these we may expect to receive in England, and we shall be curious to see how the versatile ingenuity of our American cousins can manage to improve on our own methods of making up these packets.

Allusion to this topic reminds me that some surprise is felt here at nothing having as yet been heard from your Planters' Association with respect to the letter from the Ceylon Association in London containing a suggestion as to some thirty adulterators of your teas being prosecuted. Although we believe that opinion here is opened to wholesale prosecution of offenders, there is no doubt that it would be a wise course to make periodical raids on these pests of your tea trade. To allow the system to go on of selling mixture as pure Ceylon tea with only a colorable pretext of an almost undistinguishable label intimating that the contents of a packet or mixture, must be to court the continuance of a practice very damaging to the extension of the sale of your tea, and we hope your local Association will counsel the prosecution of a few at least among the chief offenders.—*London Cor.*

◆

THE MINERAL WEALTH OF INDIA.

Captain C. C. Townsend, R. A., will find many to agree with him in his opinion that the mineral resources of India have not received adequate attention in the past, and that the country contains below its surface potentialities of wealth which might change its history and immensely improve the condition of its people. Some also, perhaps, will think with him that such attention as the subject has received has been devoted too exclusively to gold and gems to the exclusion of the so-called baser metals, especially iron, which are so much the most important factors in the history of the world as to have given names to the epochs of its existence. We fear, however, that all will rise from a perusal of his brochure with ideas very little more definite than before as to the means for the attainment of this wealth. The little book is disappointing in that it gives glimpses of great possibilities without laying down any practicable road to their realization; it demonstrates that there is mineral wealth in India, it shows the obstacles to its exploitation, but it hardly indicates, even vaguely, the means for overcoming those obstacles. The author does not claim to have evolved an exhaustive treatise; he has deliberately made his work a mere sketch in the hope that it will attract readers that a more ponderous tone would deter; but he has not made the most of the space he has allowed himself. In fact, the book contains more than the usual amount of padding. One-third of

it is occupied with the idiosyncracies of English and Indian workmen; dissertations on the recent Factory Act agitation; the relative importance in the social scale of the clerk and artisan; the repressive influence of caste upon native ambitions; the influence of irrigation upon the fertility of the soil; anecdotes of Indian candidates for the English Parliament; and other matters which, though interesting enough in themselves, have the slenderest connection with the title of the book. Its arrangement is also illogical and trying; sequence there is none, and the more cognate two subjects are the greater the distance separating them. For instance, while the author shows that the near proximity of coal and iron is essential to the commercial production of the latter (a truism by the way) half the book separates the chapters dealing with the two subjects, and constant cross reference is necessary to follow his arguments.

And now, having criticised the pudding we shall proceed to extract the plums, for plums there are well worth investigation. That India is an iron-producing country has been known from the earliest times. The armourers of Damascus sent to India for their steel; it has even been imported into England; and the bridge over the Menai Straits was constructed largely of Indian metal. But today many thousands of tons are imported into India for railway and other purposes, which, if they could be produced at home, would have an important bearing on remittances, and the far-reaching question of exchange, while they would give employment to thousands of the people of the country. The author indicates four places in India where iron has been produced to some extent on a commercial basis. The best known mines are those of Raneegeunge, in Bengal, to work which the Bengal Iron Company was formed in 1871. It proved a financial failure, and was closed in 1879, but the author argues with some show of reason that this was not due to any want of the raw material, but to insufficient capital and want of recognition by Government, owing to whose refusal to make a grant of land much additional expenditure was thrown upon the Company, and it had to borrow money at a high rate of interest. Its system of manufacture, too, was much criticised, though it certainly seemed to have possessed every element of success. The ore cost only 8 annas a ton at the furnaces, the lead for the fuel was very short, and it had limestone for flux and fireclay on the spot. The Company has been recently rehabilitated, and for the short time it has been at work is understood to have been successful. The Wadhwa Valley, in the Central Provinces, is also well known to possess an excellent iron ore, while there also are coal fields, and limestone is stated to abound. This has never been worked, and a serious difficulty here, and to some extent also at Raneegeunge, is the great deficiency of carbon in the local coal, a fault that is to a great extent common to all Indian coal, and that is fatal to its successful use for smelting purposes without expensive preliminary processes that greatly add to the cost of the product. In Cutch iron ore of good quality is said to exist, but our information as to its quality, as well as of the fuel available for smelting is limited, which is the case also of the Ohindwin Valley and several other parts of Burma where both coal and iron are said to have been found.

Of most interest to Southern India are the Salem iron fields, well known to contain ore of a very excellent quality, and which have been worked on a very small scale by natives for many years. Half a century ago the Indian Steel, Iron and Ohrome Company made iron, from Salem ore, at Porto Novo. It used charcoal for smelting, and the iron acquired a very high name as possessing

qualities similar to Swedish iron, and being especially suitable for conversion into steel. At the present day the knives made by Arnachellin at Salem have a fame far wider than the Presidency. While this Company was working it sent home large quantities of pig iron (there were no factories for working up the raw material in India in those days), and it was of some of this iron that the Menai Straits Bridge, already referred to, was made. The exact causes of the winding up of the Company have not been traced. It is believed to have had trouble with water in its mines and probably it found, even in those days, that charcoal smelting could not compete with coal. An authentic account of this Company, of its methods of working, and the exact locality and present condition of its mines, and especially the reasons which induced it to establish its works on the Coast, thus involving a long lead for the ore, rather than on the spot, when the cost of transport would have been incurred only for the less bulky pig iron would be of much interest. The hitherto insuperable bar to the extensive working of the Salem iron fields has of course been the absence of coal, and we cordially agree with the author in urging a more thorough and minute examination of the neighbouring districts with a view to verifying, once for all, whether any exists. A Royal Engineer Officer, whose opinion is entitled to respect, has declared that the cuttings of the Madras Railway in the Coimbatore District show clear signs of coal-bearing strata, and though the head of the Indian Geological Survey has spent so long a time as three days in examination and then proclaimed it to be shale, we hardly feel as convinced as we ought to be of the consequent impossibility of the existence of coal in the District, for did not the Geological Department for many years pool-pool the existence of coal at Singapore where the mines now hope to shortly turn out 1,000 tons a day? The author states that "coal is nearly always found near iron, and there appears to be no reason why Salem should be an exception to the rule." But this is rather confounding cause with effect, and the truth of the case is most probably, not that iron does not exist, but that it is hardly ever worked when coal is not near it. Again he says:—"One of the great difficulties in the way of thoroughly developing the Salem fields is the distance they are away from coal, but this distance is not so great but that a light coal tramway, laid down *ad hoc*, would pay a really large firm consuming its hundreds of tons of coal a day." The nearest coal fields are those of Singapore, which are already in railway connection with Salem; but the distance is quite prohibitive of the use of their produce for smelting purposes. Captain Townsend states that "Salem ore is so good that it would pay to take it to Calcutta and smelt it with the Kahabari coal," but he gives no figures in support of his contention, and without clear proof we are unable to believe it. The freight by rail and sea would be little short of the freight *via* Madras or Calcutta to England, and would be the equivalent of sending coals to Newcastle. He qualifies his statement further on, however. "At the same time, good fuel, within reasonable distance, would be essential to the full development of the Salem fields, for the ore is far from being the same throughout, varying greatly, and only the best would be worth exporting to Bengal—if that." In default of coal he suggests the use of charcoal, liberal forest rights being combined with extensive special plantations of babul wood. Figures are conspicuous by their absence in all his arguments, and in default of some convincing proof we cannot accept his conclusions.

Iron production by the aid of charcoal is now about to be tried in the Mysore Province, and we shall watch the result of Dr. Dhanakoti Raju's speculation with much interest; but it will be many years before this will reach a stage from which instruction can be derived. The question is, however, one of such vital importance to the interests of the Presidency that it would be worth the while of Government to depute an officer to the duty of collecting statistics as to the extent of forest available after allowing for the general requirements of the Districts, and of land available for planting of charcoal obtainable per acre of forest and required per ton of ore smelted or of iron produced, the cost of its manufacture, &c. The present head of the Geological Department in this Presidency is well qualified for the task. Another fuel alluded to is the peat produced on the Nilgiri Hills, and in view of the shortly expected Nilgiri Railway some enquiry in this direction might be useful. It must, we fear, be accepted as a fact that the cost of any imported fuel would be prohibitive. The author argues, and in this we agree, that to be a commercial success the production of pig iron must be accompanied by its manufacture into wrought iron bars, plates, rails, &c., nor assuming the fuel difficulty to have been overcome for the production of the 'pig,' should there be any obstacle, in the present advancing state of enterprise in India, to such further progress; while it is almost superfluous to point out, as the author does, the advantages to the country of being self-contained in this important respect in times both of war and of peace. There were established some years ago at Beypore Ironworks for the purpose of re-rolling rails and otherwise working up old railway iron, but it came to an early end, on account, we believe, of this same fuel difficulty. Some hazy recollection of this has caused a curious confusion of ideas in the author's mind when, on page 5, he apparently treats Salem and Beypore as convertible terms, and implies that iron has been produced at both places.

Not the least interesting chapter in the book is that which treats of the subsidiary metals to which space only permits a very brief reference. Copper is believed to have been worked in pre-historic times near Madanapore, and even worked with some success in the fifteenth century, but it was killed by the heavy royalties demanded by the Rajahs. In 1831 the Indian Copper Company was working the Nellerie Mines. "In the Goomacunda Valley, in the Kurnaul District, there exists a deserted copper mine so old that the very legend of its workers has been lost to the people living there," which has been the case also with the gold mines of Kolar. Of other metals we are told of platinum in the Andus Valley and at Kolar, mercury in the Andaman Islands, zinc in Ootycampore, tin at Ranceganje and in several parts of Burma; all showing potentialities of riches which have hitherto borne little fruit and which justify the writer's lament that "truly the mineral wealth of India has been sadly neglected." Government can do much by exploitation and publication of results and judicious concessions, and we conclude with a passage from the author with which at least, however we may have differed from some of his conclusions, we can cordially agree:—

"But the chief things wanted to develop the iron industries of India are money and experienced skill, neither of which shall we get until either some skilled capitalist is attracted to the East with a view of developing, not its gold and jewels, but its iron, or—and this is the real solution—the natives of India, or a few of them, take real interest in these matters. We see how native enterprise has developed the cotton industry of Bombay, and made it what it is—an industry the greatest in all India. This is due to the fact that natives have realised

the value of cotton and also the processes of manufacture, and are devoting themselves to its development. Let them devote themselves to the study of iron with equal zeal for five or ten years and then see what great results will arise. Let five or six of our most intelligent native youth, the sons and nephews of our great capitalists be sent by their relatives to Europe to study the iron industries as they now go to study law and medicine. Let them be not too proud to learn in the proper way, viz., as workmen, and not at first as masters, and much will be done. It is an old story but a true one, that India can be best developed by her own people, provided the people will study the right way."—*Madras Mail*.

CINNAMON.

The news received by wire yesterday, of the results of the Quarterly Sales held in London on Monday last, is not very cheering, though it cannot be said to have been unexpected. This is the third sale in succession at which fine qualities have been neglected, and a drop in prices has been experienced. In November last, fine qualities were not in demand, and were chiefly bought in. What little was sold changed hands at 3d. to 1d. less than August prices. At the February sales, out of 1582 Bales offered, only about 700 sold—fine qualities being again neglected, and largely bought in, though sellers were willing to accept 1d. to 2d. less than the previous rates. There was no private inquiry between the sales for the lots which did not find buyers; and, with the quantities sent forward since February to add to the unsold parcels, it is not surprising that a further drop was experienced. Whether the small proportion of lots which found buyers—600 Bales out of 1300—means that some holders of fine spice were firm, and bought in their lots in hopes of better prices, or that even at the decline of 1d. buyers neglected the better qualities, we cannot say. It is to be feared that the latter is the case, as a dead set seems to have been originated against fine spice, and London Agents have begun to counsel their Principals here to manufacture medium sorts. This is not the first time that Cinnamon of superior make has been neglected; but it is, so far as we know, the first occasion on which fine sorts have been neglected at three successive Quarterly Sales, selling at a decline each time, while coarser sorts have advanced almost *pari passu*. In February these sold at an advance of about 3d., and this week of about 3d to 1d per lb. This would seem to indicate a determination on the part of buyers to lower the price of fine Cinnamon, whether for speculative purposes, or from a conviction that the coarser qualities answer quite as well as the finer manufactures for most of the purposes to which they are put. The consoling features in the situation are that the fall in Exchange will, to some extent at least, nullify the fall in price; and that the current prices might help to popularise the best spice. When good times set in, there may be a brisker demand for fine qualities. Good times, we say, because the financial troubles of the principal foreign countries which consume the spice may account largely for the drop. Spain, Portugal and the South American Republics are known to absorb large quantities in their Roman Catholic Churches; and among the Continental nations the spice is used freely for confectionery, chiefly chocolates. Meanwhile, manufacturers of ordinary qualities are to be congratulated on the better demand for their wares; and there should be a rise in local prices in sympathy with the upward tendency in London. The extent to which fine qualities have been neglected may be inferred from the following figures:—

November 1890	..	3,029 Bales	...	1,520
February 1891	..	1,582	"	700
May 1891	..	1,300	"	600

The decreasing offerings do not imply a falling off in the quantities imported into Great Britain; for last year, out of 1,094,514 lb. quills exported hence,

the United Kingdom took 1,084,837 lb, and this year up to date, no less than 397,893 lb, have gone direct to London from total exports aggregating 725,648 lb. In view of the downward tendency of finer sorts, the advice of Agents in London is sound, that extra expense should not be incurred in the manufacture of fine qualities. But such are the exigencies of trade, that it is reported from the principal districts that, while old rates still rule, advances to peelers were never higher! The manufacture is in the hands of a caste; the lower the profits, the more anxious are Proprietors not to lose the season, and thereby part of their crop—there is a rush for peelers, and these delight to commence their labours in debt, and most proprietors wish that it should be so!—Local "Examiner."

JAVA CINCHONA DIVIDEND.—The dividend of the Java Cinchona Company "Kertamanah" for 1890-91 has been fixed at 11 per cent. The Kertamanah estate is one of average size. Its yield has increased from 80 to 155 tons in three seasons and the bark it produces averages from $4\frac{1}{2}$ to 5 per cent. quinine sulphate.—*Chemist and Druggist.*

THE COLONY OF THE LEEWARD ISLANDS.—The text of Mr. Morris's lecture on these islands has just been printed in the journal of the Royal Colonial Institute. It comprises a description of the natural features of the islands and their agricultural resources. As in the case of agriculturists nearer home, the colonists have manifested a tendency to put all their eggs into one basket, and with more or less disastrous results. Thanks to the initiative of Kew, and the energy of Mr. Morris, "botanical" stations, which should rather be called agricultural stations, have been instituted for the purpose of introducing and distributing tropical and other plants likely to be of economic importance and suitable for cultivation in particular districts such as Coffee, Tea, Caoutchouc in various forms, Cinchona, spices, fibre-plants, and so on. A great federation of botanical and agricultural stations, with Kew as the centre, has been the ideal of successive directors, and now the ideal is being realised. Perhaps in the future the West India Islands, or other suitable localities may be utilised as nurseries for Orchids and other tropical plants, whence the home market may be supplied somewhat as the propagating houses at Kew furnish the decorative plants for the show houses.—*Gardeners' Chronicle.*

THE WEST AFRICAN CINCHONA PLANTATIONS.—From time to time parcels of West African cinchona are placed on our market, but the extent of the plantations in the island of São Thomé, where the bark is grown, is generally believed to be very small. That view seems to be incorrect. In 1882 planting commenced in the island, and since that time two millions and a half trees have been planted in several plantations. The total exports from the island in 1890 amounted to 34,435 kilos., but a much larger export is anticipated in the future. The four principal plantation owners, with a view to obtain a better return for their money than they receive on the London market, are reported to have established a quinine-factory near Lisbon, which was to have commenced operations in May of this year, but does not appear to be working as yet. These four proprietors own 1,800,000 trees between them. The planters are endeavouring to obtain knowledge of a process, which will enable them to export, in the place of bark, a liquor containing from 25 to 30 per cent. of quinine, to be refined in Europe. Such a process would effect a saving in freight, &c., of about 20s. per cwt. on the liquor exported, and enable the growers to make use of poor barks, which it does not pay them to ship at present.—*Chemist and Druggist.*

THE GOVERNMENT of Tasmania has created a Department for conserving the Crown forests which cover over 16,000,000 acres, and promise to be very valuable. The gum trees are the most common, and some are of great size. An *Albora* blue gum 330 feet high has been observed, and there is one called "Lady Franklin's Tree" near Hobart Town which measures 107 feet in girth, a few feet from the ground. The "peppermint" tree, another gum also grows to a great altitude, especially in the humid valleys of the island.—*Indian Agriculturist.* Aug. 8th.

A SIMPLE REMEDY FOR CABBAGE CATERPILLARS.—An old and experienced ardent tells us that his invariable remedy for destroying the caterpillar is boiling water. So soon as they commence their work of destruction he fills a large kettle with water and heats it to boiling. Then taking a watering-can with a fine hose he proceeds to water the plants with the boiling water. This kills the caterpillars, and that without injury to the plants and without fear of poisoning the roots of the seedlings a danger too often attendant upon the use of poisonous mixtures or powders. We know the gentleman who gives us this remedy to be perfectly reliable.—*Southern Planter.*

WHEN we are troubled with a little sulphur or pulverised tobacco in the nest to keep vermin off the hen. When the chickens are hatched they are fed on light bread crumbs soaked in milk, as they grow older we make bread for them on Graham or shorts, taking the same pains to have it light that we would if it were bread for family use. As they grow older we mix soaked wheat with their feed. When they first come off the nest we rub a small quantity of tallow and grease on the breast of the hen. The young chickens get enough of it on them to keep off the vermin.—*Chronicle.*

VEGETATION OF URUGUAY.—M. E. Andre recently addressed the Members of the French Acclimatization Society on the results of his botanical researches in Uruguay. In planting the parks of Monte Video, M. Andre has very wisely determined to avail himself largely of the native vegetation. There will not be much difficulty in finding suitable subjects, for taking a few of the plants mentioned in M. Andre's letter promiscuously, we find the Pampas Grass, the giant Eryngium, Verbena, Petunias, gigantic Thistles, Lucerns, Eugonias, Tillandsias, Palms (*Cocos australis*), Calliandra, various Lamelias, Erythrina, and very many other suitable plants. What a pity it seems that our Indian and Colonial friends do not follow M. Andre's plan of utilising and developing the resources offered by the native flora, instead of endeavouring to reproduce under unfavourable conditions the gardens and flower-shows of Europe.—*Gardeners' Chronicle.*

THE REPORT on tea and coffee cultivation in Bengal during the past year gives the following particulars:—There were 416 plantations during the year as compared with 399 in 1889. The total area under tea was 85,203 acres as against 79,006 acres in the preceding year. But while the number of plantations and the area under tea show increase, the output of tea and the average yield per acre both show a falling off compared with 1889. The output was 24,923,269 lb. against 25,089,423 lb. in 1889, and the average yield per acre 354.8 lb. against 375.47 lb. in 1889. The Rajshybe Division heads the list with 350 gardens. Onota Nagpur comes next with 35, Ohittagong has 25, and Dacca 6. In Darjiling the output of the year in most gardens was below the average owing to drought at the beginning of the season and excessive rainfall and want of sunshine in the middle. Owing to the influenza epidemic the year was very unhealthy for the coolies. In Jaldighri the hybrid plant is most common, though in a few gardens the Obina plant may be seen. The indigenous seed from Manjpur and Assam is considered the best in this district. Jorhardaga is the only district in Bengal which cultivates the coffee plant, but it produced no coffee during the year. The only production of the year was 120 lb., which was cured out in the Hill Tracts of Chittagong.—*Madras Times.*

IN PRAISE OF TEA.

An enthusiastic lover of tea, writing to the *Globe* on the subject, says:—"But, while the wise men in Parliament are dealing drastically with water companies, and are seeing to it that we have wholesome water, is there no substitute? The road to grace is through tea, not that concoction served as such in England, but an aromatic and delicious beverage as it might be made, as indeed it is made in Russia. The English opium-eater, learned in this as in all matters, has said:—"For tea, though ridiculed by those who are naturally of coarse nerves, or are become so from wine-drinking, and are not susceptible of influence from so refined a stimulant, will always be the favourite beverage of the intellectual." The claims of tea have been fittingly put forth too by Hazlitt and Leigh Hunt. The former, in the language of a jolly toper, talks of quaffing 'libations of tea.' He could not have spoken thus and meant the bitter stuff served at thousands of ignorant tables. No; depend on it, he knew how to brew tea, and had studied the judicious quantity of the leaf which should be imbued. They certainly recognised in Swift's time that the water must boil, or my Lady Smart would not have cried, 'Lord, miss, how can you drink your tea hot? Sure your month's pay'd.' That elegant lady also bids Betty 'bring the canister,' which shows us the tea was made by those who had to drink it, doubtless for scientific as well as economical reasons. Tea then cost a round sum per pound, and an excessive infusion was injurious both to the beverage and the pocket. We may believe that a dish o' tea made from Lady Smart's canister was worth the drinking.

"Not a housewife but knows that boiling water is requisite to a sound result, but how often does the water boil at the moment? Urns brought to the table with a spirit lamp beneath are not to be despised, but they are the appurtenances of the well-to-do, and by no means common. What we want is a cheap and an easy way of heating our water, under the eye of those who brew and those who drink. The Russian samovar, a delightful invention, has been devised for this purpose, and, in case some are not acquainted with its virtues, let me describe it in a few words. The Samovar, then, is a water-jacketed urn, often very elegant in shape, composed of metal, with a funnel in the centre, at the bottom of which is a miniature grate, upon which rests the charcoal fuel used to maintain a boiling temperature. A few shavings of wood are first introduced, and, when these are in a blaze, the charcoal is added, and the samovar is ready for use. The top of the funnel or chimney is utilised to place a small tea-pot upon, thus keeping the brew from losing any of its heat. Meanwhile a choice simmer imparts to the tea-drinker a cheerful feeling, and he may now say his grace. The pot receives some boiling water, and, when duly heated and emptied one spoonful of tea is introduced for four people, which is ample. At a legitimate temperature the leaf renders its finest flavour, and it is then only necessary to fill each cup one-third full from the pot, adding two-thirds of boiling water delivered from the samovar through a tap. Tea should be drunk without milk; but, with excellent reward to the palate, a slice of lemon may be put in the cup. The Russians often take a small piece of sugar in the mouth, and pass the tea over it, instead of inserting the sugar into the tea. I see no particular gain in this habit, but am open to admit that without sugar at all the delicate essence of the leaf appeals more insinuatingly to a virgin palate; but, alas! how few of us can claim this immaculate virtue of discriminativeness. Travel where you please in Russia, every peasant has his samovar. When he marries he sets up a samovar, which outlasts his lifetime. That, and an *eikon* for his spiritual wants, is often near all he has, and he is contented. The price of a samovar is quickly saved through the economy in the use of tea, and a home-like influence is created in the poorest dwelling. In England, a samovar could be made and sold profitably for 10s., while no more artistic ornament for the table can be

imagined. And why not serve glasses of tea in clubs and restaurants at luncheon time? At twopence the glass the net profit would be greater than on a glass of beer. There is much in example, but precious little in preaching. To see a gentleman quietly sipping his tea with lemon would find imitators, whereas all the exhortations in the world are as the babbling of insanity to your average lover of alcohol.

"It is to be observed that, for some physiological cause, the nature of which has not been explained, tea and alcohol do not always harmonise in the same economy. A cup of tea taken by one who uses alcohol is not infrequently followed by a dyspeptic visit, due probably rather to the strength of the tea than to any other cause. Drink tea, however, of the proper strength, and you may swallow half a dozen cups at a time with impunity as far as perceptible harmful effects are concerned. Most of us know the fatal happy climax of wine-taking, the Apex of Lamb, beyond which you cannot go, and which you can only strive to regain, minus hope of reaching at that particular sitting the galeaty of a soul already experienced. But with tea, one can go on passing his glass. An equable, normal jollity is comfortably sustained. The brain is gently stimulated, and you participate in the ideal hilarity of Dr. Johnson. Even a health might be most properly drunk in tea. 'Gentlemen, charge your saucers,' will be perhaps the order of the future. And the saucer is a very good thing to drink from. The custom should be revived."—*D. and C. Mail*, Aug. 28th.

THE INDIAN TEA TRADE.

It was not long ago, before I had the good fortune to be entertained by a mercantile firm, that I was just as ignorant as the generality of the Indian public are to the present day, of one of India's principal trades—the tea trade. It is true that I would almost weekly notice in the daily papers advertisements of tea auctions having been held, and of thousands of chests at a time having passed the hammer; but my idea about all this was that those sales were attended exclusively by native grocers; that the tea sold was consumed entirely by ourselves in Calcutta and the neighbourhood; and that as a matter of fact, obscurity was the principal characteristic of these sales, labouring under the impression that cheap things could only be picked up at an auction. The majority of the public are today no wiser than I was before I entered the trade. It may, therefore, be interesting for them to know something about such ridiculous notions that prevail. Tea is one of the principal articles of export from India, also from Ceylon, where it may be said to be still in its infancy, notwithstanding its development within a comparatively short space of time. Indian tea is manufactured in Assam, Cachar, Sylhet, Darjeeling, the Dooars, Kumaon, the Kangra Valley and Chota-Nagpur. Assam growths are renowned for their strength. Cachar and Sylhet possess the same character, but in less degree. Darjeeling with the Dooars, the Kangra Valley and Kumaon produce flowery teas, and the last named district, tea of an inferior quality, *viz.*, appreciably devoid of either strength or flavour. Since the introduction of Indian tea the old favourite, China tea, is being universally replaced. It has completely lost its former reputation, and is year by year fast losing ground, and growing in disfavour everywhere. Indeed the day is not far removed when China tea will only be a thing of the past. The reason of this general displacement, nay expulsion, is because it has of late years depreciated very remarkably in quality, and is no longer considered genuine. Besides, it is by far more economical to drink Indian tea. In a report published by the London Board of Customs they say:—"From information which has been afforded us on the subject, we believe that we make a moderate estimate in assuming that Indian tea goes half as far again as Chinese tea, so far as depth of colour and fulness (not delicacy) of flavour are concerned. Thus, if 1 lb. of Chinese tea produces 5 gallons of tea of a certain depth of colour and fulness of flavour, 1 lb of

Indian tea will produce $7\frac{1}{2}$ gallons of a similar beverage. To add to this, the average price of 1 lb. of Indian tea is scarcely more than that of its rival.

A very small portion only of our manufacture, it will be surprising to learn, much to the shame and discredit of the Indians is consumed in India; scarcely 2 million lb. or 1-50th part of a whole season's crop is retained for local use; and as this quantity is apparently more than India, judging from experiences gained by experiments (the tottering condition of the Indian Tea Supply Company, Limited, furnishes ample proof), will ever consume, the proportion will diminish as the production increases annually. The bulk of the manufacture, therefore, is exported to the United Kingdom. Australia takes a small portion, but promises very soon to absorb more. In the season 1887-88 we exported thence 2,408,000 lb. in 1888-89 2,869,000 lb. in 1889-90 3,598,000 lb. and this season's 1891-92 exports bids fair to outstrip the last, which stands at 4,879,000 by 1,000,000 lb. America has just begun to give our teas a trial, and will soon accord them more of her patronage. French epicures are beginning to acquire a taste for our leaf, and Russia still purchases our finest descriptions.

Tea drinkers in India think it absurd to pay more than 12 annas, or at the outside R1 for a lb. of tea. What will they say to tea having been sold in London, by auction, from the Gartmore Estate of Ceylon, at R145 and R345 per lb. and in our sales in Calcutta, only so recently as the 30th of July last, at R40, R20 and R15 per lb. from the Nassau Tea Garden of the Kangra Valley District.

I shall now give a full idea as to the present position of our industry as compared with that of its rival in the United Kingdom, coupled with some other interesting facts.

From the year 1849 to 1859, China tea held uninterrupted sway; its consumption having increased from 50,000,000, to 76,000,000 lb. In 1864 Indian tea made its appearance in the field; insignificant at the time, but promising to prove a formidable foe; it kept increasing in strength, so did its rival, (the consumption of China tea having increased from 85½ millions to 118½ millions, while Indian, beginning with 2½ million lb. increased to 18½ millions within the space of 10 years, from 1864-1874; but in 1884 down fell the quantity exported by China, while Indian had almost doubled itself. Ceylon now appeared on the scene, and 1½ million lb. were consumed. In 1889 the figures stood thus:—

China tea, drunk	61,100,000 lb.
Indian	96,028,000 "
Ceylon	28,500,000 "

Thus, within a period of 26 years from 1864-1889, the average monthly home consumption of Indian tea steadily and rapidly increased from ¾ million lb., or from 3 per cent. to 67 per cent., while that of China, by various fluctuations, commencing with less than 7½ millions in 1864, and reaching the highest point, a little over 10½ millions in 1879, when scarcely 3 million lb. of our staple was drunk, ultimately fell to 5 million lb. in 1889. The rapid and extensive consumption of Indian tea has been further stimulated by the fall in prices. For instance, Medium Pekoe and Pekoe Souchongs have fallen in the course of eleven (11) years from 1860-90, from 1s 6d to 10½d and 1s 3d to 9d per lb. respectively.

Large quantities of tea are sold locally every week by auction, and good portion, the major in fact, is shipped direct to London to be disposed of there at the hammer. The teas sold here are purchased by our merchants, who, for the most part act as agents on behalf of London wholesale dealers.

The tea trade is perhaps the most risky venture extant. Great caution, much foresight, and extensive experience, to say nothing of the requisite knowledge of the article itself, are indispensable to buy to advantage. But notwithstanding, it often and often happens that purchases made here under the above conditions heavily lose money when resold in London. As a case in point: Facts and figures were so encouraging when this season 1891-92 opened, that the most cautious buyers here, supported by the advice

of their home friends (commercial), entertained the most sanguine hopes of the most satisfactory results attending their purchases and consequently paid much higher than actual value. They very soon learnt how sadly erroneous their estimates of the London market were, for, upon re-sale losses averaged from about 15 to 30 per cent. Not a single parcel of tea, even so much as "scraped out" much less shewed a profit. And cases of this kind are of common occurrence. I would, therefore, not be far wrong in saying that this business is absolutely clothed in uncertainty, as no amount of foresightedness or experience can say whether tea is going to pay or lose till it is actually sold.

Tea merchants place their interests in the hands of tea experts or tea-tasters, whose services they engage at fair remunerations. These men have to undergo a long course of training in tea-tasting before they are considered competent to manage the tea purchase department of a firm. They must be able to discern, by means of their palate, the character of a tea,—in other words, whether it possesses strength or flavour, how much of the latter or the former, or of both, and accordingly determine its value. They must not forget at the same time to throw into the account the various influencing agents of the market. They must be able, with existing facts and figures of tea statistics, to gauge the future, at least two or three months hence, for teas bought here at a certain time can only be placed on the market some two months after. Their responsibility can never be over-estimated, and it is for this condition alone that they are remunerated. Upon their shoulders, in a great measure, rests the welfare of the business. They can make or ruin a firm. Such being the case, their appointment is always at a risk, and greatly dependent upon the temperament and mercy of their employers; probably, in many places, their actions are viewed with suspicion and hence closely watched, and at reasonable opportunities scrutinized, if for no other reason, with the object of keeping them aright, and of preventing irregularities. They can, therefore, be never too careful, and must always look a dozen times before they leap, lest they should take a false step, and thereby render themselves open to rebuke. In relation to their employers their position is acutely delicate.

Not so the tea broker, or the independent individual in whose hands merchants place the disposal of their teas by auction. It is true he has a lot of running about to do, and a great deal of worry, and sometimes a lot of snapping and snarling to accept with all deference and humility, and under choking sensations, which he has to bridle much to his own discomfort; but he has the satisfaction nevertheless of knowing that he is a free agent. It is true that he gives his labour for a nominal sum of one rupee for every 100 rupees of tea sold, and a similar return for every 100 rupees of tea bought, but as nothing can be sold or bought according to commercial rules, relating to the tea trade, without his mediation, he turns a decent penny monthly. He can afford to pay R250 per mensem to the boarding house keeper; as much or more in addition to his club for sundry pegs, etc.; keep horses and conveyances and have left, after all such moderate expenditures, ample to retire upon after 6 or 9 or, not to be too inconsiderate, say 10 years of service. He can always obtain market value, which is his own value, for a tea. It would be unreasonable to expect a better result of him, and he does not care a hoot whether you do or you do not. He is of all labourers the most independent, and least taxed, nevertheless the best remunerated. Merchants may come and merchants may go, but he goes on for ever. Every labourer is worthy of his hire, he knows this well, and he is pretty certain of his. News of every description he has always on the tips of his fingers to suit each of his customers according to each one's immediate requirements, and he can spot it out with a sympathetic assurance. A tea broker, like others of the same fraternity, is an anomaly. He goes to the tea seller and whispers confidentially to

him that tears are about to lose in order to gratify his avarice; the very next moment, in the presence of the buyer, he blaudly and innocently contradicts himself. I said before that a large proportion of the season's crop is shipped direct to London for sale by auction there. The tea broker abhors this foolish system of business; he has no sympathy either with it, or with its promoters, and is unceasingly at pains to destroy it for his own aggrandizement. He evinces great concern for a merchant's welfare, although in his heart of hearts he cares not a straw whether a merchant fails or prospers. It affects him little one way or the other. A tea broker is a man of circumstances, better, a man of fine sympathetic tendencies, and in this respect resembles the cold obameleon. He can at a moment's notice sadden at a man's losses or gladden at his profits, and in this fashion keep changing and re-changing the colour of his feelings during his daily calls according to each one's needs. He believes himself to be over worked, but can still find enough of time to indulge in golf, tennis, cricket, and football, each in its proper season. Indeed he has so much leisure at his disposal that by excessive practice he excels in all manner of pastimes. He is one of the many who argues that "all work and no play makes Jack a dull boy." In all sincerity he is heard to say that it is not for the sake of playing so much as wise regard for his health that he does play. In short, the tea broker is a clever, happy-go-lucky fortunate fellow; and his motto is "Live and let live."—"Quill" in the *Indian Empire*.

GOVERNMENT CINCHONA ENTERPRISE IN BENGAL.

From the annual report of the Government Cinchona plantation and factory in Bengal for the year 1890-91, it appears that the whole of the crop, with the exception of a small quantity supplied on indent sold to Government institutions, was sent to the Fehrigu factory for disposal. The output of the factory showed a decrease in the quantity of cinchona febrifuge as compared with that produced during the preceding year: but there was a marked increase in sulphate of quinine, of which 4,010 pounds were manufactured, against 1,833 pounds for the year 1889-90. The revenue derived from the sale of sulphate of quinine, cinchona, crystalline febrifuge, cinchona barks, and other products of the plantation was in excess of that derived from the same products in the previous year; while the net profits of the year's working, which amounted to Rs17,040, are considered satisfactory. The resolution on the Report states that, in starting the cinchona plantations, the Government did not aim at a profit, its object being to secure for the people a cheap remedy against fever. The quinine manufactured at the Government factory can now be sold at one rupee per ounce, and Dr. King observes that it would be possible still further to reduce the price if all the charitable dispensaries in the country were to supply themselves with the Government drug instead of buying it elsewhere. It is stated that the Government drug is purer, and the Inspector-General of civil hospitals will be asked to consider what steps should be taken to extend the demand for Government quinine, in order to bring about a further reduction in price. Judging from the tenor of the resolution on the Report, it would appear that institutions helped by Government may expect to be requested to draw their supplies of quinine from the Government factory. It will be interesting to know what the Inspector-General of Civil Hospitals will have to say on the subject, and how the charitable and other dispensaries view the enterprise.—*Statesman*.

ECHOES OF SCIENCE.

Platinum is a very useful metal in science, because it resists corrosion, and has a co-efficient of expansion nearly equal to that of glass, so that it can be safely fused into glass without fear of fracturing the latter under changes of temperature. Mr. R. A. Fessenden, of Roseville, New Jersey, U. S., has, however, discovered an alloy of iron, nickel, cobalt,

silicon, and gold or silver, which can be used as a substitute for platinum. The co-efficient of expansion for glass is 85, that of platinum 95; whereas that of the new alloy can be made exactly the same as that of the glass with which it is to be employed. Hence for vacuum tubes in particular it will be very useful, as the air will not be able to enter at the point where the metal penetrates the glass on account of any unequal shrinkage.

To prevent the frightful accidents which happen on steamships through the bursting of the copper steam pipes, the Fairfield Shipbuilding and Engineering Company of Govan began the practice of lapping the pipe outside with copper wire. They found, however, that copper wire loses much of its strength on being heated, and have since tried Delta metal, which, at the temperature of melting tin, or 412 deg. Fahr., was found to be much superior to copper not only in strength but in ductility.—*Globe*.

BARK AND DRUG REPORT.

(From the *Chemist and Druggist*.)

LONDON, Aug. 20.

CINCHONA.—The cinchona auctions which were held this week again of very moderate extent, the quantity offered for sale consisting of—

	Pkgs.	Pkgs.	
Ceylon bark ..	738	718	were sold
East Indian bark ..	987	659	"
Java bark ..	97	97	"
South American bark ..	182	24	"
Total ..	2004	1493	"

There were a few parcels of fine bright druggist's barks from Madras and several lots of good official's cinchona, also from British India; but on the whole, the assortment offered nothing of importance the following are the quantities purchased by the principal buyers:—

Agents for the Mannheim and Amsterdam works ..	100,008
" Auerbach works ..	63,530
" Frankfort o/M and Stuttgart works..	69,180
" Brunswick factory ..	51,478
" Italian and American works ..	50,884
Messrs. Howards & Sons ..	22,211
Sundry druggists, &c. ..	21,290

Total quantity of bark sold .. 368,650

Bought in or withdrawn .. 88,567

Total quantity offered .. 457,226

The tone throughout the auctions was miserably dull, and about 20 per cent. of the bark (mostly East Indian cinchona from Bombay and Calcutt) was bought in owing to insufficient competition. The price paid were hardly up to the low standard of the last auctions, and the unit is nearer 1d than 1½d per lb.

It should be well understood that the mere weight of bark purchased affords no guide whatever to the quinine yield represented by it; firms who buy a small quantity of bark by weight frequently take the richest lots, and vice versa.

No detailed figures about the Java shipments for the year ending June 30th are yet to hand, but the following may be taken as approximately correct:—

	1887	1888	1889	1890	1891
	lb.	lb.	lb.	lb.	lb.
Amsterdam	2,280,000	3,493,000	4,415,000	4,750,000	6,000,000

being an increase over the season preceding of 87, 26, 8 and 27 per cent. During the month of August of the last three years the shipments are given as follows: 1889, 700,000 Amst. lb.; 1890, 760,000 Amst. lb.; 1891, 1,000,000 Amst. lb.

OILS (ESSENTIAL).—Citronella, in tins, 11-16d; in bottles, 3d per oz., on the spot; and for delivery 10½d per lb. in tins and 11d per lb. in drums, c. i. l. terms.

QUININE.—The market remains very dull, and the total sales reported during the week only amounted to about 35,000 oz. at 10d per oz. for German bulk from spot until January delivery. On Wednesday night a sale of 5,000 oz. spot was reported at 11½ per oz., but it is doubtful whether that transaction actually took place—at any rate, there are no further sellers at the figure today. A New York correspondent writes under date of August 18th: "Quinine is very dull with us, and we think will go lower. P. & W. reduced their price 2 cents this week. There is practically no demand for any large quantities."

THE DUTCH MARKET.

AMSTERDAM, AUG. 24.

The analysis of the cinchona bark offered at the bark sales in Amsterdam on September 3rd shows the following results:—The manufacturing bark contains about 9 tons sulphate of quinine, or 4.19 per cent, on the average. About 8 tons contain 1.2 per cent, sulphate of quinine; 37 tons, 2.3 per cent.; 75 tons, 3.4 per cent.; 88 tons, 4.5 per cent.; 34 tons, 5.6 per cent.; 24 tons, 6.7 per cent.; 8 tons, 7.8 per cent.

STEPHANITE.—A NEW FLUX.

A number of gentlemen interested in the manufacture of iron and steel, recently visited the works of Messrs. H. Young & Co., Ecclestone-street, Pimlico, with a view to investigate the properties of a flux, named after the inventor, the late Mr. Stephan. The addition of aluminum to iron has lately received a considerable amount of attention, owing to the fact that the resultant product is of much improved quality, providing that the admixture is properly effected.

Various methods have from time to time been brought forward to secure this end, amongst which we may mention the ordinary addition of the aluminum to the charge in the cupola, but it has been found in practice that the aluminum is, in operation, dispersed by the action of the blast; another method is to add it to the molten charge in the ladle, but this practice requires the aid of stirrers, and it has been found that an uniform admixture does not result, the operation producing a merely mechanical mixture, and not a homogenous metal.

The Stephanite process, however, seems to overcome these difficulties; certain proportions of alumina, lime, and emery are taken and incorporated and pressed into briquettes, which are added to the charge of iron and coke in the cupola, in the proportion of 80 lb. of Stephanite to one ton of iron. The action which is then said to take place is that the temperature of the furnace converts the alumina into metallic aluminum gases, which the molten metal readily absorbs. The result is, that instead of a mechanically mixed compound, a chemically perfect mixture is produced.

One of the claims of the Stephanite Company of London-wall, who are introducing this invention, is that the flux acts as a strong clearing agent, and that every particle of metal is separated from the slag. The Company was fortunate enough to have the foundry of Messrs. Young placed at its disposal for these experiments, and on the day of the demonstration, Messrs. Young agreed to have the whole of their castings run from the new compound.

At the demonstration, the cupola was charged with three tons of low quality scrap iron and 240 lb. of the flux. Immediately the metal was run off, its great fluidity was perceived from its behaviour in the ladles, and as a consequence, it follows that better castings are obtainable, and blow holes are, to a great extent, avoided. Several most severe tests were applied to some of the day's castings, in one instance two castings were taken from the moulds whilst at cherry heat and plunged into cold water. This test, instead of utterly spoiling the castings, as would be imagined, simply resulted in the production of a splendid steely metal, as was at once seen on breaking a cooled casting. The file test was applied, and it was found that the merest superficial scratch was made. One half of a casting was afterwards heated in a forge and cooled in the air, and it was found to be soft, and amenable to the file;

the same piece was afterwards reheated and again plunged into cold water at cherry heat, and it was then found that the file once more made no impression on the metal.

This new metal—for practically it is a new metal, being really a combination of iron and steel, produced direct from the cupola without the aid of any after manipulation—met with general approbation from those present, the prevalent opinion being that the results were remarkable, and that the invention is capable of very wide application. It only remains to be said that divers grades of metal may be produced by a variation of the proportions of iron and Stephanite.—*Manufacturer and Inventor.*

A VOYAGE TO THE COCOS ISLANDS.

H. M. S. "Rattler" returned last Wednesday from the annual visit to the Cocos Islands, having on board Mr. Egerton, Commissioner to the Cocos.

The "Rattler" left Singapore on the 25th July and calling at Batavia, anchored off Christians Island. The anchorage there is particularly bad even in the S. E. Monsoon when it is sheltered. The "Rattler" dragged and had she not been under steam, the results might have been serious. During the N. W. monsoon, landing is impossible. Christmas Island is situated about five hundred miles to the S. E. of Java Head. The island is about the size of Singapore, is of considerable height, and is covered with vegetation. The present population consists of one of the brothers Ross and eight natives. Mr. Ross has taken over the whole island for ten years, after which period he will pay a sum annually to the British Government. So far, very little has been done in the way of cultivation for want of labour, but the soil is rich and perfect for planting purposes. The island abounds in a species of large blue or slate coloured pigeon, which is almost tame and is excellent to eat. The frigate bird and other sea bird are also seen in thousands and the small green pigeon is abundant. A kind of ground thrush is also common. The settlement on the island—the metropolis in embryo—consists so far of a few huts. The natives who are with Mr. Ross have come from the Cocos Islands. Twice a month the schooner "J. G. C. Ross" calls at the island en route to the Cocos from Batavia.

Leaving Christmas Island, the "Rattler" proceeded to the Cocos or Keeling group. The Cocos Islands are entirely of coral formation and are very low. The group is in the form of a horseshoe, and the water, immediately around and between the islands, is so shallow that it would be possible to walk right down the group at low tide. The present Governor, Mr. Ross lives on the main island with his daughter, and the population has increased to above 540 (Mr. Egerton took the census during the "Rattler's" stay at the islands). Mr. Ross's rule appears to be excellent. So far, there has been no crime whatever, and, considering the fact that there are no laws properly so called and no police, this clean record of twenty-three years may be considered almost phenomenal. Mr. Ross's power, of course, is practically absolute. Lately he has suffered heavy losses. His sheep have died, and his deer in swimming from one island to another have been eaten by sharks in considerable numbers. At one time, the plague of rats was so great that it was feared the coco-nut palms would be exterminated by them. As a preventive measure, Mr. Ross imported a number of cats. The cats

soon however, ran wild, and did much havoc among the pigeons and small birds. Mr. Ross has since obtained a remarkable breed of fox-terriers which are more successful. These dogs go out in batches of twenty-five, every day, and the rat mortality is steadily on the increase. As in Christmas Island, the large slate-coloured pigeon is abundant. A number of deer were seen, and jungle fowl are beautiful and not exceedingly difficult to get at. Fish are very plentiful and on a lake in the North Keeling Island, Mr. Ross has a breed of sea salmon or salmon trout which afford excellent sport for fishermen. A large green fish of heavy weight is plentiful. During the visit, the people on the "Rattler" caught two of these fish, one weighing 88 pounds and the other 50. For table purpose, it is said this fish cannot be surpassed. Altogether, to the naturalist or sportsman, the Cocos would well repay a visit. Shells in great variety and of great beauty are plentiful everywhere; specimens have been brought back in the "Rattler," ranging in size from large shells of the oyster tribe which two or three sailors can barely carry, to tiny shells of which a thimble would hold a dozen. The inhabitants have a wonderful collection of boats, and some of Mr. Ross's Una built boats would compete for speed with anything of their class anywhere. The islands have passed through one or two strange experiences of late years. Some seven years ago, when a volcano, 700 miles off, in the Straits of Sunda, was in eruption, the air became so full of scoriaceous matter that almost total darkness prevailed for forty hours literally as in Egypt of old this was a "darkness that could be felt." It can in fact be picked up by handfuls still in some parts of the island. Again some years ago a terrible typhoon struck the islands and destroyed almost everything. So violent was it that, in Mr. Ross's own house, there was not a single piece of furniture unbroken by this storm that crashed in doors and windows as if they were the flimsiest of obstructions. The only currency in the island is the notes signed by Mr. Ross, ranging in value from five rupees downward. These are used as cash for all kinds of trade and other insular transactions, and, when a man is leaving the islands, Mr. Ross gives him a cheque for any notes he may possess. The coral growth of these islands is sufficiently rapid to upset Admiralty survey doings continually. Mr. Ross estimates that above a certain depth the polyps build at the rate of nine inches a year. In course of time, this coral growth will join the islands into one. The officers of the "Rattler" have made new surveys during this voyage, so that at present, the soundings are known well enough. The anchorage at the Cocos is excellent.—*Straits Times*, 1st. September.

A JAPANESE OPINION ON TEA.

A Japanese merchant whose views are reproduced in the *Jiyu*, delivers the following opinion about the future of the export trade in tea and silk:—"The most important staple of export in Japan is silk, and after it come tea, coal, and rice. The future of the trade in silk and tea is not bright. * * * As for tea, which stands next to silk on the list, there is a demand for it in America and Russia; but in its case also the outlook is not good. Looking at the figures of the export trade during the past six years, we find that in 1885 the value of the tea sent abroad aggregated 6,854,120 yen; in 1886 it rose to 7,720,320 yen; in 1887, it fell to 6,603,341 yen; in 1888, to 6,120,000 yen; in 1889, to 6,150,000 yen, and in 1890 to 6,320,000 yen. This declining, or at best stationary, condition is due to various causes, the chief of which appears

to be gradual development of tea cultivation in China, India, and Ceylon, tea, of which places is onsting onrs in Western markets. The export of Indian tea in 1887 amounted to 80,500,300 lb., in the following year it rose to 89,783,000 lb., and in 1889 the returns showed 92,590,000 lb. Russia, again, to which Japan has turned of late for a market, is beginning to grow quantities of tea on her own account, so that the prospect for importers becomes less and less encouraging. On the whole, I conclude that for Japanese sericulturists and tea-men aliko the out-look is far from favourable.—*China Mail*.

LONDON TEA LETTER.

As regards the prices obtained for small single boxes of Fancy Tea, it seems hardly fair to those who have obtained good prices for real, commercial, breaks, to place the former in the "Honour List," thus causing the more profitable Commercial Lines, to take a lower position on the "Honour List" than their real merit entitles them to. As any *chota sahib* in his first season on Tea, could, if he were allowed to play the fool, turn out a small box of these Fancy Teas, the "Honour List," will, for the above reasons, the Season, take precedence of the "Fancy List," the latter being quoted, rather for the "fun of the thing" than for any more weighty reason

PLANTS SEEING.—It is odd to think of plants as seeing, but Mrs. Robert King describes an experience in India that she regards as confirming her husband's theory that creeping plants have some faculty akin to sight. Mr King was seated with one foot against a pillar, when a kind of convolvulus growing near was seen to turn towards his leg, which was then kept motionless until, at the end of an hour, the tendrils had laid themselves over it. He then went to breakfast, and on returning found that the plant had turned away in disgust. A pole was procured and placed against the pillar about a foot from the nearest sprays of convolvulus, and in ten minutes they had begun to curve toward it, and in a few hours the tendrils had twisted quite around it. The pole was on the side away from the light, and the observers find it difficult to account for the phenomenon except by assuming that the plant could see the pole.—*Mildura Cultivator*.

[It more likely felt by some subtle influence the existence of an object suitable for its support. —Ed. T. A.]

UNFAVOURABLE REPORTS ON TEA.

A writer in the *Indian Planters' Gazette* has an amusing passage, thus:—

You will find that, as a rule, the agency firms describe and report upon your samples fairly and as compared with other teas actually being made. The appetite for fine quality has, however, in several instances (there is one particularly had offender in London) led to a practice of reporting upon samples as compared with what one would imagine would be the quality of Utopian produce, supposing that province grew tea. This firm habitually made the teas out many degrees worse than in reality, with singular contempt for the intelligence of their Managers, to whom they kept up a standing cry of *wolf*. Now this is not a way to treat a tea-house sirdar.

Their vocabulary did not run from "very good" to "very bad," but from about "moderately fair" to "infamous." The results were that the reports simply misled you.

One especially awful report I got, I remember, was such that even the experience of several seasons failed to reassure me that there was not something really wrong with the teas at last, but when the sale report arrived they came out fifth upon a list of eighteen. And the mystery to me has been ever since, what (with the English language at its present strength) could the Agents have found to say to the maker of number eighteen teas. The only possible solution is (to my mind) that they had recourse to vulgar French abuse, and reported somewhat in this fashion.

General Remarks.—Cré nom de pommadeterre Corblou.—

(Sd.) GANNONADE & Co.
Disgrace Church St. E. C.,

7th October 18—.

THE BRITISH BORNEO COMPANY, (LIMITED.)

The ordinary half-yearly meeting of the shareholders in this Company was held yesterday, at the Cannon-street Hotel, when Mr. A. J. Sorntton occupied the chair.—The landed property of the Company, the report stated, now amounted to about 10½,000 acres, all of which was covered with valuable timber. A large portion of the land was suitable for growing tobacco, coffee and sugar, and should the development of Borneo continue in these products, it should be saleable for planting purposes in the future, more especially as it was easily accessible from Sadakan, the capital. As suitable virgin land was getting scarce in Sumatra, the attention of the large Dutch companies was being attracted to Borneo, and it was hoped that they would commence there. The general manager in Borneo had been dismissed. The Board had despatched a special representative to Borneo, who was of opinion that, with a suitable manager there, and more shipping facilities, their trade with China alone would show a sufficient profit to pay the Company. The Board did not think they were warranted in proceeding with the cultivation of tobacco, next year, on account of the low price of tobacco and the high price of labour in Borneo. The report then entered into details with regard to matters complained

* Miquis.

of in the island.—The Chairman expressed regret at the character of the report which was submitted, and he attributed the unfortunate position they were in to the late manager, who had failed to appreciate the responsibility of his position. To this fact, and the existence of exceptionally serious circumstances in Borneo, they attributed their position. The country was very slow in development, which was partly due to the want of appreciation on the part of the local Government. They were seven or eight weeks' sail from their property, which obliged them to trust very much to their representative. On some of the contracts entered into by their late manager they had lost several thousands of pounds, and their loss had been increased by a want of adequate supervision. They had had great difficulties with the labour question, which was seriously felt by all the trading companies in the island. Their timber was most valuable, and the markets of the world were open to them. He moved the adoption of the report and statement of accounts.—Mr. J. J. Dunn seconded this motion, and also alluded to the great value of their timber; but on the trading account they had lost about 5,000l.—Mr. R. V. Williams suggested that a drum-head court martial should be held upon the directors and immediate punishment inflicted, because of the miserable tale of mismanagement which was disclosed by the report. They had found a scapegoat in the person of their late manager, but the real fault lay at home. He hoped the Shareholders would keep in touch with each other, and set in such a way as to enable them to bring pressure upon the Directors, and give them a chance of redeeming their character.—Mr. O. P. Bennett, who had visited Borneo, gave an account of the vast quantities of timber which they possessed, and maintained that in China alone there would be an unfailing demand for what they could send.—Several Shareholders expressed their great dissatisfaction with the state of affairs as disclosed by the report and statement of accounts. One or two suggested that a Committee of Shareholders should be appointed; but to this exception was taken, on the ground of the difficulty of controlling an estate so far from London. Another proposition was to adjourn the meeting for two months for fresh accounts to be prepared. Ultimately the Shareholders agreed to receive and adopt the report and statement of accounts, the Directors on their part agreeing to prepare fresh accounts, showing the position of matters down to June, and to call another meeting in a few months' time.—After some formal business the meeting terminated.—*London Standard*.

HONOLULU AND HAWAIIAN VEGETATION.

Honolulu is situated under the lee of a range of mountains about 4,000 feet high, that almost entirely break the trade winds and as a consequence the climate is sweltering in the day time, but the nights are cool and pleasant.

Trade is somewhat depressed on account of the McKinley hill. Sugar is the principal article of export and the price has gone down so much that they say there is no profit in it. Heretofore they have been making from 40 to 90 per cent on their sugar and it goes hard to have to come down to 10 to 25 per cent, which they will have to do. The quantity exported amounts to 125,000 tons for this year and they have been getting \$100 a ton. It costs about \$50 a ton to manufacture it and after the freight is added, left them a large margin of profit.

It is now thought that some of the poorer plantations will have to shut down entirely as they can get no one to carry them on. The average yield is from three and one half to four tons per acre. Some plantations or parts of them yield as high as seven tons per acre. There are not many places that will yield that however.

There are two methods of extracting the sugar from the cane, the old roller process and the more recent diffusion process. All the new mills now being erected

are for diffusion. In this method the cane is cut into very thin diagonal slices, dumped into iron cells and water and steam turned on. The sugar and nothing else is extracted and the juice is almost absolutely pure. It is claimed that they get 93 per cent of the sugar from the cane. In the old process they do not get over 80 per cent; the diffusionists claiming a saving of from 12 to 18 per cent. There are now three new diffusion plants going up. The Ewas 18 miles from this city and Kabuka 30 miles away—both 50 ton mills, that is, with a capacity of fifty tons of sugar a day. The other, Mekkiwilli is on Kauai and is a 100 ton mill. The machinery of the two former are being built here while the larger one is coming from Scotland, a considerable portion of the stock being held there.

There is considerable rice grown on these islands. There are two crops a year. The winter crop matures in about 140 days and the summer crop in about 20 days less. It is grown almost entirely by the Chinese. No other race of people would take the trouble they do. The rice is first sown thickly broadcast and the water turned on to it. When it gets the proper size it is transplanted in small bunches of eight or ten stalks about a foot apart—the men wading about in the water planting it in the mud. The water is probably six to eight inches deep. The water is kept on it almost the entire time. The first crop is now being harvested. The yield from the islands is about 15,000 tons of which 5,000 is exported, the balance used here.

Besides sugar and rice about the only other article of export is bananas. Every steamer takes a large number of bunches—from 3,500 to 7,000 and even more. There is but one variety shipped, the Chinese dwarf. Good ten hand bunches are worth \$1 here. The freight to San Francisco is 75 cents and sometimes when the market gets overstocked there is heavy loss. One party told me some time ago that they had over 3,500 bunches in store in San Francisco and expected to lose a great part of them. We can buy ordinary sized bunches at from 15 to 25 cents.

There are quite a number of hides shipped from there, here being no tanneries.

Coffee culture is coming to the front and several companies have been formed for its cultivation. It grows wild in many places and yields very abundantly and is of very superior flavor. The best I ever drank I have got here. It wants to be three or four years old to be good. If used younger it has a green, oily taste, and the older the better. It sells here at 45 cents per pound at retail.

Pineapples are plentiful and cheap, retailing at from 5 to 25 cents each for the native varieties, and 50 cents to \$1 for imported varieties. I saw some sugar loaf pines that weighed nearly 10 pounds which sold at \$1 each.

There is a strong feeling here favorable to annexation to the United States. Some think that it is the only remedy for the stagnation in business caused by the decline in the price of sugar. It is hard to tell or foresee what the result will be and many are very anxious about it. It is said that there are several hundred white men organized and fully armed for any emergency.

H. J. RHODES.

—Rural Californian.

FORESTRY IN MADRAS.

The likes and dislikes of particular trees, in respect of shade, undergrowth, moisture and other conditions, have evidently still to be studied, as also the effects of such individual peculiarities as time of seedling, that is, whether before or after the firing season, and as to which species reproduce best by seedlings and which by coppice. As to the complaints that rank undergrowth and long grass, the first effects of protection, choke seedlings, it has been suggested that if more time were allowed them to become more strongly rooted, they would be able to push through or outgrow, this slight objection. The failure in the natural reproduction of teak in the teak forests has been ascribed to the inability of the seed to reach the ground through the fallen leaves with which it is

covered. But it appears that rose-wood seedlings have been found in a forest, in which mature rose-wood trees did not occur. In regard to young teak and *Hardwickia* seedlings supposed to be withering from drought it is found that while so appearing, they are often actually making underground growth, which in a year or two enables them through the depth of their roots, to resist the effects of dry weather. Although coppicing is unsuitable for *Casuarina*, it has been successfully tried with satto-wood and *Terminalia tomentosa* in the Bellary district, and with the *eucalypti* on the Nilgiri hills. The forests of the Madras Presidency have generally shown good growth, where protection has been efficient, even on the most unpromising areas, and a copious reproduction of the more valuable trees, such as teak, rose-wood, *Hardwickia*, sandal, satinwood and *Pterocarpus marsupium* has been attained. The only district in which protection and reproduction have been bad is South Arcot. Nor was artificial production less attended to, or less successful comparatively. The amount spent on plantations, topes and cultural operations was Rs. 1,701, against Rs. 5,743, and the area operated upon was 50,631, against 49,319 acres in the previous year. The increase was chiefly under plantations; while no addition was made to the topes. Teak at Nilamber, bine gum on the Nilgiris, and *Casuarina*, were the more valuable trees included among the new plantations. In the Southern Circle, beside *Casuarina*, which was put down on a most extensive scale, cashewnut, mango, jak *didi-didi*, aruott, tank, palmira nut, *Acacia planifrons*, mahogany (*S. macrophylla*) were sown or planted; while, in the Northern Circle, *Casuarina*, mim, tamarind, *Cassia tora*, Arabian dates, were sown in the plains, and mahogany, teak, *Frenela* and *Pinus longifolia* were planted out on the hills. The clearing of creepers and undergrowth was continued in both circles, it is believed with good effects in respect of reproduction. Some difficulty and expense are anticipated in eradicating the prickly pear, which has taken a firm hold in the fuel and fodder reserves of the Coimbatore district. As regards the cultivation of exotics, the results of experiments vary. Dates are said to germinate freely, but the after casualties are numerous in the more wet districts on the coast. Offsets appear to be of stronger constitution than seedlings, but they are more difficult to obtain. *Carob* is reported to have grown well and borne fruit; it is a useful tree and its seed should be distributed to be sown in suitable localities. Of the various species of *Eucalyptus* which were tried on the plains, all, with the exception of *E. robusta*, failed, germinating well but dying soon after. *E. robusta*, seems likely to thrive in the plains. At slight elevations, however, such as the Palmanu, Wynnad, North Coimbatore and the Pannasain hills, the *Eucalypti*, *citriodora*, *resinifera*, *puniculata* and *rostrata* do fairly well. Giant bamboos grow well in the Wynnad, in Nilamber and South Canara. *Ipecauanha* in Nilamber is full of promise. Mahogany shows healthy and vigorous growth in the moister climate of the Presidency. Although the various rubber trees are said to be thriving, no information as to their yield has been furnished. A special experiment with silk is also in progress under the supervision of the Honorable Mr. Garstin. In addition to the revenue derived from the sale of timber and fuel, bamboos, and minor produce, the department has been realizing a handsome income from grazing fees, which have risen from Rs. 1,138 in 1883-84 to Rs. 1,43,945 in 1888-89, with the prospect of a still further rise under a gradual and cautious enhancement of the fees to the maximum of the sanctioned rate. But any sudden increase in the burdens imposed upon cattle-owners is to be avoided. The main object of imposing a charge upon grazing is not, we are told, to increase the revenue, but to restrict the number of cattle feeding in the reserves and so to improve the sources from which future demands for fodder can be met. The plan upon which the Madras Forest department has been working seems to us to be well calculated to make the local forests a progressively increasing source of revenue; and the results of its operations during 1888-89 cannot but be regarded as full of encouragement.—*Indian Agriculturist*.

NOTE ON COMMERCIAL OIL OF CITRONELLA.*

BY JOHN C. UMNEY,
Pharmaceutical Chemist.

The more common Indian grass oils, known in trade as verbena, ginger-grass, and citronella, the products respectively of *Andropogon citratus*, *A. Schenanthus*, and *A. Nardus* differ considerably in appearance. The first two are usually of a yellowish brown colour; the third varlos, being sometimes yellow, at others emerald green, the yellow oil generally becoming green on exposure to light.

In order to determine on what the difference in colour of this last and the change from yellow to green which takes place depend, eight samples of citronella oil were obtained from various sources, and a small quantity of each exposed to direct sunlight. Of this number five (A, B, C, F, G) were decidedly green before exposure, two (D and E) were yellow at first, but rapidly became green, whilst one (H) was yellow originally and underwent no change. The fact that the presence of copper has been shown (Gribourt and Ilsted) to be reason of the green colour of commercial cajuput oil, led me to suspect the same contamination in the case of this oil. (Since writing this note my attention has been called to the fact that Kremers † mentions incidentally the presence of copper in a sample of this oil which he examined.)

250 c.c. of the sample A was shaken with a dilute solution of ferrocyanide of potassium, when a rapid separation of a red precipitate took place, which after washing with spirit to free it from traces of oil and then with water to remove any excess of potassium ferrocyanide, was proved to be ferrocyanide of copper. Examination was then made of all the samples, with the following results:—

	Sp. gr. at 15° C.	Colour.	Remarks.
A	.896	emerald green.	copper present.
B	.895	greenish.	"
C	.890	"	"
D	.887	yel., becoming green.	"
E	.896	"	"
F	.896	emerald green.	"
G	.897	greenish.	"
H	.870	brownish yellow.	{ copper entirely absent.

From the fact that only those samples which were green, or became so on exposure, contained copper, it appeared almost certain that the change in colour might be due directly to the presence of that metal, which was readily proved by precipitating all the copper from the most unmarkedly green sample, by treatment two or three times with solution of potassium ferrocyanide, when the oil became pale yellow in colour. One portion of this oil was then exposed to sunlight for some days and a second to the heat of a water-bath in an open porcelain dish for twelve hours without any change whatever in colour taking place. A third portion of the oil was treated on a water-bath for a few minutes in presence of a very small piece of copper foil, when the oil rapidly assumed its original green colour, thus showing conclusively that the green coloration of the oil is due to the presence of a trace of copper, and that its removal causes the oil to assume its natural color, namely, yellow.

The green coloration of the oil was destroyed on heating to 50° C., and at a higher temperature an acid distillate was obtained which was proved after neutralization to consist principally of acetic acid. It seems possible, therefore, that the metal exists in combination with this acid, the change in colour on exposure to light either depending on oxidation of an aldehyde present to acetic acid, or on the partial decomposition of an ester of acetic acid

contained in the oil. Varying statements exist as to the specific gravity of pure citronella oil, for whilst Messrs. Schimmel state that it should not fall below .895 at 15° C. (*Pharm. Journ.* [3], xx., 264), Dodge (*Pharm. Journ.* [3], xx., 855) assigns to it a gravity of .877 at 16° C. It will be noticed that sample H, which contained no copper, was of lower specific gravity than the others, and fell considerably below the limit proposed by Messrs. Schimmel. This sample proved, on examination of its solubility in 80 per cent. spirit, to be adulterated with petroleum, as was readily proved by fractionation, and the absence of copper is probably due to its distillation in the earthen or iron stills, now only used by the poorer native distillers. The quantity of copper present, without doubt derived from distillation in stills of that metal, is, of course, very minute, but it seems desirable to call attention to it, as pointing out that pale yellow, and not green, is the natural colour of citronella oil.

DISCUSSION.

Mr. C. UMNEY said it was very desirable that pharmacists should be aware of the changes which took place naturally in drugs and other matters with which they had to deal. Essential oils they all knew were prone to oxidation and change, as was seen in the case of essential oil of almonds, which one day might be quite limpid and the next almost a solid mass from crystallization due to oxidation, or in essential oil of camomile, which would be one morning quite white, and the next a beautiful blue colour. Oil of cajuput, again, was sometimes rejected because it was white and had not the green copper colour they were accustomed to. It was very important to know when these changes were due to natural causes and when to sophistication or defects in manufacture. Citronella oil was a very large article of commerce, being imported enormously from Ceylon, where the grass from which the oil was distilled grew in such luxuriance that they had nothing to do but gather it and put it into the still, and the oil came to this country almost for nothing, the price being only about one-tenth what it was some few years ago. It was quite clear that there was often a defect in manufacture which could be remedied by having the head of the still well tinned, and by having the worm of tin or earthenware. That, however, would not prevent sophistication. Petroleum was very cheap in most places, and the citronella oil which came to London was often adulterated with it, sometimes only to so small an extent as to arouse suspicion, but sometimes to such a large extent that those who understood such matters simply marked "petroleum" against it in their catalogues and paid no further attention to it. This paper would put people on their guard, and would enlighten those who like himself had been under the impression that this charge of colour was due to a similar cause as that which took place in camomile oil and not to defects in manufacturing or sophistication.

Mr. HOLMES said the specimens of citronella oil in the Museum had never been green; and it seemed therefore that the method of distillation must have been altered of late years. The question of adulteration with petroleum was of great importance, as essential oils were more frequently adulterated than most drugs, and the fraud was often difficult of detection. American essential oils were much worse than those in this country, which might account for the fact that the specific gravity mentioned in American text-books was not always correct. The same thing had been noticed in the case of sandal-wood oil.

The PRESIDENT said it would appear that the so-called sophisticated oil was in fact pure, the green colour being only due to distillation in copper. He did not know whether anyone could throw any light on the reason for adding petroleum. Apart from any question of gravity it would probably be useful in preserving the flavour of the original oil.

Mr. CHARLES UMNEY thought possibly the petroleum was put into the still with the grass. Formerly this oil and also oil of verbena came to this country in bottles which had been sent out with wine or brandy, but these essential oils now came over either

* Read before the Pharmaceutical Society of Great Britain, at an Evening Meeting in London, April 8.

† Proceedings American Pharmaceutical Association, 1887, p. 562.

in tins or sometimes in huge cisterns, weighing half a ton. It was in these large packages that adulteration with petroleum had chiefly been found.

Mr. Moss remarked that it did not necessarily follow that the mode of manufacture was altered, because at the present time both green and colourless citronella oil came into the market, the difference being due to the different nature of the apparatus in which it was produced. If this apparatus were a very primitive one, a tub, a clay head, and a bamboo stem, there would be no trace of copper, but with a more modern still, if the copper were not well tinned inside, there might be the green colour.

The PRESIDENT said he was rather suggesting that the petroleum might be put into the still primarily to prevent oxidation or change during the process of distillation.

Mr. C. UMNEY said his belief was that the petroleum was added because it was cheap.

Mr. BATTLE said he had been rather struck with the statement in the paper that citronella oil with distinct traces of petroleum did not show the copper colour, and he might state the result of an experiment—accidentally made—which he witnessed at Dover on the previous day. A child was coming out of an oilshop with a wine bottle containing about a pint of petroleum oil, when, owing probably to the neck not having been wiped, the bottle slipped from the child's fingers and was smashed on the pavement. At that moment he was about twenty yards off, and by the time he got to the spot, he found to his surprise that the petroleum oil was rapidly turning a greenish blue wherever it came into contact with the cement with which the pavement—blocks of patent Victoria stone, about two feet square—was laid; it was evidently the cement and not the stone which was giving the colour. He was inclined to think at first that this was an indication that the petroleum had been distilled in copper, and was rather surprised to hear Mr. Umney's remarks. When he returned home he should take steps to ascertain the composition of the cement in question.

Mr. J. C. UMNEY, in reply, said Mr. Moss had remarked that some commercial oil of citronella was yellow, rather implying that it contained no copper and would not turn green; but he might say that he had procured eight samples from different sources, out of which seven went green, though five of them were quite yellow at starting. He thought the reason that the light oil did not change colour was that it had been distilled by poor people, and that petroleum had been added, being cheaper, to increase the yield. Richer people using more modern appliances got a full yield and had no need to adulterate. The sp. gr. of the oil in America was stated in a recent paper by a Mr. Dodge to be .877, which was rather a peculiar statement, and might account for some of the analyses.

The PRESIDENT then proposed a vote of thanks to Mr. Umney for the paper, referring to the fact that he had been a pupil in the School of Pharmacy and was then working in the Research Laboratory. The vote was passed unanimously.

Sir,—I have perused with much interest the paper on "Commercial Oil of Citronella," read before the last evening meeting by Mr. J. C. Umney. Some years since I had occasion to conduct some experiments on citronella oil with the same object in view, and as my results pointed in some respects to slightly different conclusions from those arrived at by Mr. J. C. Umney, it may be useful to record them now that the subject is under notice.

Two samples of oil were operated upon: one a new one from an original bottle, the other an old one. The former was pale yellow, whilst the latter was green. Two bottles filled with the first sample and hermetically sealed were placed, one in sunlight and the other in darkness. Two other bottles were half filled and the stoppers removed daily after well shaking; one of these was exposed to sunlight whilst the other was kept in darkness.

The two samples which were in the full bottles remained unchanged in colour for the month whilst under observation, but of those in the partly filled bottles the one exposed to light had become green, and the one in darkness also, though not to quite the same extent. An elevation of temperature was afterwards found to accelerate the change.

The other sample was next operated upon. A portion was distilled from a fractionating flask and the distillate was set aside in successive portions and exposed in partly full bottles. The first three portions of distillate did not change in colour, but the last one slowly acquired the green tint of the original. The small portion of residue in the flask and the last distillate were both found to contain copper.

The foregoing seem to indicate that the development of the green colour in those samples containing copper is caused not by the action of light, as assumed by Mr. J. C. Umney, but by oxidation.—E. H. FAIR, Uckfield.—*Pharmaceutical Journal*, April 18th.

CROPS IN SOUTHERN INDIA.

SEASON TELEGRAM TO THE GOVERNMENT OF INDIA, REVENUE AND AGRICULTURAL DEPARTMENT, SIMLA.

Week ending 5th September. Rainfall good in Ganjam, Vizagapatam, Godavari, Kurnool, Anantapur, Cuddapah, South Canara and parts of Kistna, Nellore, Bellary, North Arcot, Chingleput, South Arcot, Malabar and Nilgiris; very little elsewhere. Rainfall to date very much below average in all districts, except the three northern and the West Coast districts, Tinnevely and Nilgiris. Prospect slightly improved in parts of Chingleput and South Arcot, but more rain urgently wanted in a large number of districts, and agricultural operations suspended in several. Water, pasture and fodder growing scarcer and cattle mortality increasing in affected areas. Prices rising in Godavari, Kurnool, Anantapur, Cuddapah, North Arcot, South Arcot, Salem, Coimbatore, Tanjore, Trichinopoly and Madura; falling slightly in Ganjam, Vizagapatam; Kistna, Bellary, Madras, Nilgiris, South Canara and Travancore; stationary in the rest. Coolies employed on works—6,710 in Chingleput, 6,721 in Wandiwash, 3,387 in Kalabasti, 6,965 in Coimbatore, 3,953 in Nellore, 1,707 in Cuddapah, 415 in Malabar and 147 in Tinnevely. Number fed at kitchens—2,019, including 590 women and 1,142 children, in Chingleput; 1,659, including 312 women and 1,100 children, in Wandiwash; 29, including 14 women and 13 children, in Cuddapah; 2,084, including 458 women and 1,488 children, in Kalabasti and 199 in Coimbatore. Loans granted from commencement of distress Rupees 2,88,441 in Chingleput, 96,455 in Wandiwash, 18,027 in Cuddapah, 1,280 in Nellore, 22,996 in Coimbatore, 19,820 in Tinnevely. Wells constructed—981 in Chingleput, 33 in Coimbatore, 26 in Wandiwash, 25 in Cuddapah and 34 in Tinnevely; under construction—1,926 in Chingleput, 1,022 in Wandiwash, 245 in Cuddapah, 104 in Coimbatore, 68 in Tinnevely and 4 in Nellore.

INDIA.

The authorities at Kew, in conjunction with the Government of India, have devised a scheme for the organisation of a botanical survey of India, and the wolding of the scattered departments into a federation with the Calcutta Botanic Gardens as the centre. The details of the scheme are given in the current number of *Nature*, from which we condense the following particulars, noting, by the way, that this is only another illustration of the general principle upon which the Director of the Royal Gardens, Kew, is working to secure a regular organised Botanical Department for the whole empire, varied in detail according to circumstances and requirements, and of which the staff shall be so selected, that any man who enters may rise by successive steps to the highest position.

The Botanic Gardens, Soobpur, Calcutta, is officially recognised as the acknowledged centre of the Botanical Survey of India, to which should be referred the solution of all problems arising out of the practical or scientific study of India botany. Dr King, the Superintendent of the Royal Botanic Gardens, Calcutta, thus becomes, henceforth, the Director of the Botanical Survey of India. Dr. King will especially undertake the direction of the botanical survey of Burma and Assam.

The investigation of the Flora of the Madras Presidency and of the Hyderabad and Mysore States, has been entrusted to Mr. M. A. Lawson, the Government Botanist and Director of Cinchona plantations.

In Bombay, Dr. Cooke, Principal of the College of Science, Poona, is officially recognised as in charge of botanical research in that presidency.

The Director of the Botanical Department, Northern India, is Mr. Duthie, formerly the Superintendent of the Botanic Garden, Saharanpur. Mr. Duthie accompanied the Black Mountain Expedition, and acquired information concerning the flora of the country, which had, hitherto, not been botanically explored. During the last three years, Mr. Duthie has also been deputed to Simla, in the hot weather, to assist in the preparation of the *Dictionary of the Economic Products of India*, and during the same period he has been actively engaged in the botanical exploration of Rajputana and the central provinces. Neither the Straits Settlements nor Ceylon are included in the scheme, they being Crown colonies.—*Gardeners' Chronicle*.

CEYLON TEA FUND.

Minutes of proceedings of a meeting of the Standing Committee of the Ceylon Tea Fund held at Kandy on Friday, the 18th day of September 1891 at 1 o'clock in the afternoon.

Present:—Messrs. Giles F. Walker (Chairman, Planters' Association of Ceylon), Sholto G. D. Skrine (Chairman, Dikoya Association), A. G. K. Borron (Kandy Committee), W. Sandys Thomas (Chairman, Dimbula Association), A. L. Cross (Kandy Committee), C. S. Armstrong (Hewaheta District), T. C. Huxley (Kandy Committee), A. T. Karlsako (Kandy Committee), W. D. Gibbon (Kandy Committee), E. Hamlin (Kandy Committee), J. Anderson (Kandy Committee and Matale West District), Hon. Lt. H. Kelly (Kandy Committee), J. H. Barber (Kandy Committee), Wm. Forbes Laurie (Kandy Committee), and A. Philip (Kandy Committee), Secretary, Planters' Association of Ceylon.

The notice calling the meeting was read. The minutes of proceedings of a meeting of the Standing Committee of the Ceylon Tea Fund held at Kandy on Friday, the 14th day of August 1891, were taken as read and were confirmed.

Read letter from Mr. Robt. A. Fraser.

Read letter from Mr. H. H. Boyd. Resolved:—"That the letter be acknowledged and the Committee regrets being unable to meet Mr. Boyd's views."

Read letter from Mr. A. T. Cathcart. Resolved:—"That it be stated in reply to Mr. Cathcart's enquiry that the cost of the Tea referred to will be borne by the 'Tea Fund.'"

Read letter from Mr. A. W. Salmon, Victoria British Columbia, North America, on the subject of opening up a Tea Trade between America and India. Resolved:—"That the letter be referred to the Ceylon Tea Company, Limited, under the patronage of the Planters' Association of Ceylon."

CEYLON TEA AT THE WORLD'S EXPOSITION AT CHICAGO IN 1893.—Read letter from the Colonial Secretary forwarding by desire of the Governor copy of a circular despatch from the Secretary of State on the subject of the Chicago Exhibition of 1893, and enquiring what steps the Association proposes to take for the purpose of exhibiting Ceylon Tea at that Exhibition.

The Planting member in Council stated that he was authorized to intimate that a sum of Rs50,000 would

be granted by the Government for a Ceylon Court at the Chicago Exhibition.

Resolved (i):—"That the Standing Committee of the Tea Fund desires to express its appreciation of the action of Government in promising a vote of Rs50,000 towards the representation of Ceylon at the Chicago Exhibition."

Resolved (ii):—"That Government be informed that the Standing Committee of the Tea Fund has set aside a sum of Rs30,000 for the purpose of pushing Ceylon Tea at the forthcoming Chicago Exhibition and that the Standing Committee has requested the Chairman and the Planting member in Council to confer with Government on the subject of further arrangements."

Resolved (iii):—"That the Planting member in Council be asked to confer with the American Consul in Colombo with reference to space at the Chicago Exhibition and previous correspondence."

Read letter from Mr. E. Hoollin, The Oriental Bank Estate Company, Limited.

Read letter from Mr. J. J. Grinlinton transmitting extracts from a letter recently received from the President of the Ceylon Tea Planters' Tea Company, New York, and conveying to the Planters' Association and to the Standing Committee of the Tea Fund Mr. Elwood May's cordial thanks for the assistance afforded him in recent resolutions.

CEYLON TEA IN RUSSIA.—Read letter from Mr. William Martin Leake, Secretary, Ceylon Association in London advising demand draft of Rs3,453-21 being equivalent at 1s 5½d per rupee of £250 sterling paid by Mr. Rogivue's instructions to his London Agent. Resolved:—"That the letter to Mr. Rogivue returned through the Post Office be forwarded to him through the Secretary of the Ceylon Association in London together with the envelope and that Mr. Rogivue be requested to furnish the accounts asked for as soon as possible."

NEW ZEALAND AND SOUTH SEAS EXHIBITION.—Read letter from the Government Agent, Western Province, enquiring whether certain articles exhibited from Kalutara had been received. Resolved:—"That the letter of the Secretary to the Government Agent dated 31st August 1891 be confirmed."

Read extract of a letter from Mr. W. Mackenzie regarding the Ceylon Tea in New Zealand. Resolved:—"That the matter be referred to the Ceylon Tea Company, Limited, under the patronage of the Planters' Association of Ceylon."

FINAL ARRANGEMENTS AS TO LEASE OF "KI KIO" AT COLOMBO TO THE CEYLON TEA COMPANY LIMITED, UNDER THE PATRONAGE OF THE PLANTERS' ASSOCIATION OF CEYLON.—Read letter from Mr. Wm. Mackenzie. Read letter from Mr. James Sheriff. Resolved:—"That in reply it be pointed out that the Association is precluded by the terms of its lease from Government from selling the Tea Kiosk, and that the Standing Committee trusts that under the circumstances Messrs Mackenzie and Sheriff will reconsider their proposed idea, realizing as they must the impossibility of this Committee carrying out the individual wishes of every subscriber to the Tea Fund."

Considered and discussed final arrangements as to the Lease of the "Tea Kiosk" at Colombo to the Ceylon Tea Company, Limited, under the patronage of the Planters' Association of Ceylon. Resolved:—"That the recommendations submitted by the Sub-Committee of the Standing Committee of the Ceylon Tea Fund appointed for the purpose of establishing a Tea Kiosk at Colombo be and they are hereby accepted."

CEYLON TEA IN PARIS AND THE CORRESPONDENCE WITH THE COMMITTEE OF THE CEYLON ASSOCIATION IN LONDON.—Resolved:—"That the consideration of this subject be postponed to the next meeting."

Laid on the table prospectus of the Palais Indien Tea Houses, Limited.

ANALYSES OF SAMPLES OF TEA GROWN AT VARIOUS ELEVATIONS.—Read letter from the Secretary Ceylon Association in London submitting a proposal to obtain analyses of samples of teas grown at various elevations (at sea level, 3,000 feet, 4,500 feet and 6,000 feet above sea level) for the purpose of determining the percentage of Tannin in each sample, and also if

funds were sufficient the percentage of Theine. Resolved:—"That consideration of the subject be deferred to next meeting of the Standing Committee."

SAMPLES OF SOILS FROM CEYLON TEA ESTATES FOR THE PURPOSE OF ANALYSES AND COMPARISON WITH TEA SOILS IN INDIA.—Read letter from the Secretary, Ceylon Chamber of Commerce, Colombo, transmitting copy of a letter received from the Bengal Chamber of Commerce on the above subject. Resolved:—"That the letter be acknowledged and that it be stated that the matter will be considered."

CEYLON TEA IN THE TRANSVAAL, SOUTH AFRICA.—Read letter from Mr. Alex. Wardrop regarding opening up a market for Ceylon Tea in Johannesburg. Resolved:—"That the letter be referred to the Ceylon Tea Company, Limited, under the patronage of the Planters' Association of Ceylon."

CEYLON TEA IN PERAK (MALAYA): GRANT TO MR. C. R. HANSON.—Read letter from Messrs. Whitall & Co. intimating the delivery of 160½ pkts. to Mr. Hanson's order for free distribution in Perak as per resolution of the Committee on 14th August.

CEYLON TEA IN TASMANIA.—Read letter from Mr. W. Jones, Colombo, on the subject of a Tea Agency in Tasmania.

Read letter from Mr. Geo. Finlayson, Roslyn Forth, Tasmania. Resolved:—"That the letter be acknowledged, and that it be suggested that application might be made to the Ceylon Tea Company, Limited, under the patronage of the Planters' Association of Ceylon."

The Standing Committee of the Tea Fund then adjourned.

A. PHILIP,

Secretary to the Planters' Association of Ceylon.

CHINA VS. CEYLON TEA—"THE DANGERS OF TEA"—"GOLDEN TIPS" FROM NAHAKETTIA ESTATE—BRITISH BORNEO TRADING AND PLANTING CO.

London, September. 4th.

There is very little intelligence for me to convey to you by this mail having special relation to Ceylon. Even if it were not the fact that such matters are just now experiencing a lull, the further fact that most of our Ceylon community are as yet out of town would prevent my obtaining information with respect to them.

In my last letter mention was made of some letters appearing in the *Globe* depreciatory of the qualities of Ceylon tea in comparison with those of China. By those letters an effort, it was evident, was being made in the interest of the China tea trade to persuade home drinkers of teas that Indian and Ceylon growths were simply poisonous as compared with those of China. My opinion was expressed when mentioning these attacks on your tea to you, that we should soon see the other side of the question taken up in defence; and in the issue of the *Globe* for the 29th August there appeared the following letter, which, as coming from a medical man, will be possessed of material value in educating the opinion of the public at large. This letter reads:—

"THE DANGERS OF TEA."

Sir,—I cannot in justice to the Ceylon tea industry allow the fallacious statements of your correspondent "A Connoisseur" to go uncontradicted. It is quite evident that he knows nothing of the subject he writes about. He says that Indian and Ceylon tea contains ten times more tannin than Chinese tea. As the latter contains, as a rule, about ten per cent, it follows, if your correspondent is correct, that Indian and Ceylon teas are more than all tannin. Ceylon tea is really the most delicate of all. The reason tea is injurious when it is so, is that people will buy cheap tea, and then not take the trouble to make it pro-

perly. The price of tea and its flavour depend upon when the leaf is plucked and how it is harvested. The finest tea is plucked in the bud, and if your readers can imagine plucking the buds of a gooseberry tree, and plucking the leaf when it is fully developed, they will see what I mean. The fuller matured tea leaf is coarser and more full of tannin than the bud tea or half-developed leaf. Tea to be healthy should only be infused eight minutes: if infused longer, the bitter extractive and tannin are brought out, and those spoil its flavour. As a dietitian I always recommend my patients to drink Ceylon tea only. I get mine direct from a Ceylon plantation, and I think if your readers did the same they would soon give Chinese tea a wide berth. Ceylon tea is machine made and is not handled and pressed like Chinese tea by the hands and feet of the Mongolian, and this is a great desideratum. Ceylon tea has a great future before it, but, unfortunately, cheap, coarse Chinese tea is often palmed off as the produce of the "Gem of the Eastern Sea."—Yours faithfully, N. E. YORKE-DAVIES, L. R. Coll. Phys. Lond., &c. August 28th.

We think here that the above letter expresses pretty fully the fallacies so speciously put forward by the attacking parties in the *Globe*, and that it will be all that is necessary to set your production right with the British public.

Did I mention in my last letter the sale of some "golden tips" in Mincing Lane last week at the rate of £35 the pound? It is my belief that I did, but at all events if this was not done you are sure to have heard of it from other sources. This sample was grown on the Nahakettia estate in Ceylon, and Mr. Delmegg tells me it was brought into the sales-rooms under a glass cover, and that great curiosity and noisy excitement was shown about it. Mr. Delmegg also tells me the funniest part of the business is that some "golden tips" of equally good quality had been sold in the Mincing Lane sales-rooms the week before only at from 7s 6d to 10s the pound! But it seems to have been understood beforehand that an attempt would be made to purchase this tea for exhibition abroad, and for some reason or other this induced exceptional competition, the high price eventually secured being the result of this. We see from this fact that it is not an inherent quality in the description of prepared tea which dominates its price on the market, but simply any chance demand arising for it for the purposes of advertising.

You in Ceylon have so many friends and relatives working in some position or other in Borneo, that we expect here that many of your less well-informed residents look upon that island as a sort of El Dorado. We fear these will be sadly disabused when they read the report following of what took place at the meeting this week of the British Borneo Trading and Planting Company. We wish we could get private letters from these residing in the island telling us of what their experience is. According to what passed at the meeting we are kept as yet in entire ignorance of what the real facts connected with European life in Borneo are. [See page 270.]

There have been this week shown to me some new-fashioned tea boxes, the body of which is made in tin in one piece, the head and bottom being closed by straw-board which is made to fit into a groove pressed in the tin and then closed by a folding angle iron which grips the board within the groove and is fastened by a single screw only. There is much that is ingenious in this arrangement, but I am quite certain that a tin tea box will never stand the rough handling of a journey home. The prices quoted for a 50 lb. chest is 2s 6d f. o. h., of course packed flat and open; but experts tell me that price would be quite prohibitory.—London Cor.

VEGETABLE "BUTTER."

Somo time ago the London *Grocer* called attention to a new industry which has sprung up in Germany, especially at Mannheim, for the manufacture of "butter" from vegetable sources. So far this industry has been successful, and now we hear that it is spreading into Franco. M. F. Juen, writing in the *Moniteur Scientifique*, recently stated that the manufacture of a vegetable butter from the oil obtained from coconuts is developing into a large business in France as well as in Germany. D. Schlink's method is the one most favored by manufacturers. It depends upon the treatment of the coconut oils with alcohol and animal charcoal, which removes the volatile and fragrant fatty acids of the aromatic oils, and make the oils perfectly white. The product thus obtained is a perfectly white mass, of the consistency of butter, and of a sweet neutral, agreeable flavour melting at 25 deg. cent., and remarkably free from any tendency to turn rancid. Its analysis reveals the following composition: Fatty matter, 99.632 per cent.; mineral matter, 0.011 per cent.; water 0.357 per cent. Experiments conducted by various medical men on the indigestibility of vegetable butter go to show that it exercises no harmful influence upon the animal functions.—*American Grocer*.

IRRIGATION IN EGYPT.

1.—THE NILE BARRAGE.

In 1842 a French engineer, named Mongel Beg, suggested the building of barrages across the river, where it divides into the Rosetta and Damietta branches, about 12 miles below Cairo, and of combining with these fortifications of considerable strength for the purpose of arresting the progress of any invader, and storing munitions of war. The idea exactly fell in with the military views of Mehemet Ali, who proposed to make the Nile bifurcation a sort of military capital, and the works were sanctioned and started in 1843. The barrages consisted of two long masonry dams or bridges, the arches of which when closed were to hold the water up, or opened to permit the passage of floods. There were 61 of such arches in the Rosetta barrage and 71 in the Damietta, with locks for navigation on each side of both; the object being to keep the water at the same level in all seasons so as to entirely supersede the necessity for lifting throughout the district below, and remove the difficulties of navigation when the Nile fell to its lowest. Mehemet Ali died in 1848, and in 1853 his successor, Abbas Pasha, dismissed Mongel Beg and directed another engineer, Mazhar Beg, to finish the work on Mongel Beg's plan. In 1861 it was completed at a cost of £1,800,000, exclusive of forced labour, an additional sum, estimated at about 2½ millions sterling having been spent on fortifications, canal heads, &c. As was not uncommon in Egypt a very large percentage of these sums must have gone to the *etcetera*; nothing like 4 millions was ever forthcoming in masonry.

Cracks appeared almost as soon as the work was finished: a part gave way when the gates were closed; the water worked under the foundation and extensive settlements occurred. Repeated commissions of inquiry sat on it. In 1867 it was abandoned altogether, and finally pronounced a hopeless failure. In the next 15 years it was nothing but an impediment to navigation, the passage of the locks being a difficult and expensive undertaking. Add to this many of the channels below had fallen out of use, others had been so neglected as to be capable of a very small proportion of their proper duty, had become in fact not so much canals, as natural channels in which the Nile rose and fell without any regulation whatever. When Sir Colin Scott-Moncrieff and the staff of Anglo-Indian engineers, were called in to carry out the policy of Lord Dufferin, it was notorious the whole system of Egyptian irrigation had for years been steadily going down hill from bad to worse. While giving every credit to these officers, there is, however, no necessity to depreciate their predecessors, the French engineers. In the

first place, the latter to a great extent no doubt had their hands tied by the Pashas, had often to snit their schemes to the political notions of the day. The country is hardly provided with means of communication, and instead of touring about and seeing matters for themselves, they had to direct Arab subordinates from Cairo. In the second, with all their scientific training, they had not the practical experience of the Anglo-Indian officers, who throughout their service had been accustomed to deal with very similar conditions, to adapt means to ends in every possible way, to be engineers, contractors, and revenue officers, and in India to deal with very similar Oriental people. What they so successfully accomplished in Egypt their brother officers have been doing equally well every year in this country.

Such was the state of things in 1883, obviously not particularly hopeful. There was a proposal on foot for a system of irrigation by pumps to cost some £700,000 down, and £250,000 yearly for maintenance. But before embarking on this Sir Scott-Moncrieff decided to give the old barrages, neglected for 15 years, a trial. Some bits were patched up in 1884 and 1885, at a cost of £44,000; the water was kept up during the first low Nile season to 7 feet, and the next year to nearly 10 feet, which accomplished much. Fortune favoured the enterprise; there was a bumper cotton crop, the cultivators and commercial community were delighted with the result, the merchants of Alexandria voted an address. In 1885 the great Powers authorised the loan of a million sterling for special constructional works, and last year saw the chief engineering work of modern Egypt successfully completed, at the modest cost of about £120,000.

The foundations of the barrages rested on fine river sand and Nile mud. When the gates were closed, the difference of level between the water of the Nile above and below the dam was very considerable; during the low Nile of June 1885 this difference amounted to 10 feet, and the percolation by hydrostatic pressure under the foundations varied proportionately, as this difference increased or diminished. The problem to be first solved was therefore to counteract this tendency, either by some form of construction that should provide greatly increased depth of foundations, or by broadening these out horizontally. In the case of existing foundations, the former was obviously impracticable, and any adequate additional vertical protection would have been of doubtful value, if not of prohibitive cost. The engineers, therefore, fell back on their Indian experience of similar work. For instance, in the case of the Okhla dam across the Jamna below Delhi, the river is a mass of loose rubble stone with absolutely no foundations, which holds up successfully 10 feet of water. There the construction is so broadened out that the weight of the river per lineal foot is about 40 times as great as the weight of water pressure against it. In the case of the Nile barrages, it was determined to make the weight of the submerged masonry bear a ratio of not less than 50 times this pressure. A solid bed of Portland cement, 4 feet thick, was put over the old flooring and under the arches. An up-stream apron about 85 feet wide, and a heavy masonry pavement of dressed stone below were added, as also a row of sheet piling 16 feet deep along the edge of the apron. The difficulties of this construction were enormously increased by the springs constantly met with as the work proceeded, and by the necessity to hold up the water during the low Nile season every year. A few arches could only be dealt with at a time, enclosed by carefully constructed earthen coffer dams and assisted by continuous pumping. Preliminary operations were begun in March 1886, the work was taken up in real earnest in 1887 under Lieutenant-Colonel Western with Mr. A. Reid as the Resident Engineer, and the whole practically completed, both for the Rosetta and Damietta branches, with permanent heads for the Beherah, Menoufeh and Tewfik canals last year. For the new regulators wrought iron gates have been provided, worked by travelling cranes, with Mr. Stoney's patent rollers, and an excellent tramway runs over the whole length of both bridges to the offices, work

shops, and to the station on the railway from Cairo, for there are now railways on both sides of the Nile.

It is impossible to assess in figures the enormous benefits of a work like this to the people of Egypt, the boon it is to the fellahen in diminishing forced labour, and in almost every way to the cultivating and commercial classes. To take a single instance, while the work may be said to be still incomplete, for its full benefits have hardly yet been felt, the cotton crop of the delta has alone increased in value to the extent of £800,000 a year, a very large share of which has most certainly to be credited to the barrages and speaks volumes as to their financial result.—*Pioneer.*

THE AMSTERDAM CINCHONA SALES.

(Telegram from our Correspondent.)

AMSTERDAM, Thursday evening.

At to-day's cinchona auctions, 2,553 packages Java bark sold at an average unit of 6 cents (= 1 1/2 d. per lb) which is a very slightly lower figure than that prevailing at the last London auctions. Manufacturers' bark in quills, broken quills, and chips, sold at 10 to 47 cents per 1/2 kilo. (= 1 1/4 l. to 8 1/4 d. per lb.); ditto root at 9 to 42 cents = 1 1/2 d. to 7 1/2 d. per lb.; druggists' bark in quill, broken quill, and chips, 11 to 11 1/2 cents (= 2 d. to 1 s. 8 1/2 d. per lb.); ditto root, 11 to 13 cents (= 2 d. to 2 1/4 d. per lb). The principal buyers were the Brunswick factory, Messrs. C. L. Schepp & Zoon, of Rotterdam, and the Auerbach works.—*Chemist and Druggist*, Sept. 5.

THE EXPORT OF TEA FROM INDIA TO AFGHANISTAN.

A telegram to the *Madras Mail* summarizing Mr. O'Conor's Review of the Indian Foreign and Transfrontier trade for 1891 says:—

Mr. O'Conor takes the case of a camel load of Kangra tea of the value of Rs140, consigned to Kabul or Bokhara. In its transit to the former town 62 Kabul rupees will be levied as Customs dues by the time it has crossed the Oxus. At Kilif the charges will amount to 138 Kabul rupees (Rs106 India currency) or about 76 per cent of the value of the tea. But the troubles of the trader are not over even then. "Tea has to pay 2 1/2 per cent *ad valorem* at Bokhara value, being the value there and not what was the value at Peshawar." The conclusion arrived at is that, adding to this the cost of conveyance by camel between Peshawar and Bokhara (Rs1) it is cheaper to ship tea from Bombay up the Persian Gulf and send it through Persia, where the 5 per cent duty clears it through the country.

NOTES ON PRODUCE AND FINANCE.

WHO SHALL DECIDE?—When medicine men and analysts disagree the consumer acts wisely in deciding the case for himself. Some correspondence has appeared in the *Globe* about the respective merits or demerits of China, Indian, and Ceylon tea. One of these scribes rehashed the old story about the quantity of tannin in the latter. In answer to this "Yorke Davies, L. R. Coll. Phys. Lond., &c." writes as follows:—"I cannot, in justice to the Ceylon tea industry, allow the fallacious statements of your correspondent, 'A Connoisseur,' to go uncontradicted. It is quite evident that he knows nothing of the subject he writes about. He says that Indian and Ceylon tea contains ten times more tannin than Chinese tea. As the latter contains, as a rule, about 10 per cent., it follows, if your correspondent is correct, that Indian and Ceylon teas are more than all tannin. Ceylon tea is really the most delicate of all. The reason tea is injurious when it is so is that people will buy cheap tea, and then not take the trouble to make it properly. The price of tea and its flavour depend upon when the leaf is plucked

and how it is harvested; the finest tea is plucked in the bud, and if your readers can imagine plucking the buds of a gooseberry tree, and plucking the leaf when it is fully developed, they will see what I mean. The fully matured tea leaf is coarser and more full of tannin than the bud tea or half-developed leaf. Tea to be healthy should only infuse eight minutes; if infused longer the bitter extractive and tannin are brought out, and these spoil its flavour. As a dietitian I always recommend my patients to drink Ceylon tea only. I get mine direct from a Ceylon plantation, and I think if your readers did the same they would soon give Chinese tea a wide berth. Ceylon tea is machine made and is not handled and pressed like Chinese tea by the hand and feet of the Mongolian, and this is a desideratum, Ceylon tea has a great future before it, but, unfortunately, cheap, coarse, Chinese tea is often palmed off as the produce of the Gem of the Eastern Sea." Thereupon another correspondent, Carl H. Gold, says:—"You must allow me to inform your other correspondent, Mr. Yorke Davies, that the result of some experiments, made a short time ago, show the relative proportions of tannin to be as follows:—

Mark of Sample.	Percentage of tannin by weight extracted by infusion for 3 minutes.	Percentage of tannin by weight extracted by infusion for 15 minutes.
A	11.30	17.73
B	7.77	7.97
C	9.37	11.15
D	9.89	12.03

A was the finest Assam; B the finest China; C Common Oongou; D the finest Ceylon.

"I think," says Mr. Carl H. Gold, "that the above analysis will clearly prove that China still produces the best and purest tea." But, fortunately, consumers do not accept this statement.

LAST WEEK'S SALES.—Of last week's sales the *Produce Markets Review* says:—"The demand for Indian tea shows greater activity, and a good business has been transacted, generally at firm prices. Excepting on Monday, when about 15,000 packages were offered, the public sales have been small, and up to the present the quantity catalogued is less than that of last week; this falling off, however, is only temporary, as the imports are large, and the market will be well supplied later on. Many of the teas from the Assam and Darjeeling districts are of good quality and have fetched firm prices, while the finest parcels sold at very high rates. These high values, however, are not likely to be maintained, and a considerable fall may be expected when the immediate requirements of the trade are satisfied. Less Ceylon tea has been offered, and a recovery in the prices of all grades has resulted. The advance has been only fractional, however, in the lower descriptions, and teas at from 6 1/2 d. to 7 1/2 d. are still remarkably cheap, but Pekoes from 7 1/2 d. and upwards show a distinct improvement. Broken teas are again generally dearer, but extremely good value is still obtainable at from 10 1/2 d. upwards; indeed, these grades are undoubtedly the cheapest on offer, many of them being good enough in leaf to suit any district, and they much surpass any other class of teas in water. The general quality of the teas offered has been distinctly better, and it is to be hoped that growers will strive to maintain the improvement. Finest descriptions, although rather more plentiful, are still scarce, and command high prices. The public sales comprised 18,644 packages, of which 2,120 were withdrawn.

TEA DRINKING IN AUSTRALIA.—Mr. Christie Murray, who after his stay in Australia is again in London, noting in a piece written by himself, says that the Australian uses strong language, drinks strong tea and strong liquor. "In all up-country places," says Mr. Murray in his second article on "The Antipodeans" in the *Contemporary*, "men drink tea. They drink it all day long and at every meal in amazing quantities, and at a most unwholesome strength. The method of preparation is simple, and one would think that if the aim were to

brew a concoction altogether poisonous it ought to be effectual. On Sunday morning the tea-maker starts with a clean pot and a clean record. The pot is hung over the fire with a sufficiency of water in it for the day's brew, and when this has boiled, he pours into it enough of the fragrant herb to produce a deep coffee-coloured liquid. On Monday night removing yesterday's tea leaves he repeats the process, and so on to the end of the week." It is quite true Indian and Ceylon teas, together with proper instructions how to brew them were known in "up country" stations. Mr Murray's opinion of Australia comes to this:—"There is no country in which so high a condition of general comfort, so lofty a standard of proved intelligence, and such large and varied means of intellectual existence exist side by side with so much turbulence, so lax a commercial morality, and such overwhelming statistics of drunkenness and crimes of violence."

PLANTING IN JAMAICA.—The prospects of Jamaica are looking up, according to the official reports of Sir Henry Blake, the Governor of the island. Although the sugar crop, the staple of the island, has undergone a terrible decline, and is still decreasing, Sir Henry does not believe that it has ceased to be "a safe and profitable investment," under altered conditions. He declines to accept the theory that the abandonment of sugar estates is attributable to the low price of sugar, and the difficulty of obtaining labour. The Governor thinks there has been improvidence in the system of cultivating the canes, and a lack of science in the methods of manufacturing sugar and rum. Sir H. Blake regrets, for an especial reason, that sugar planting should be given up. The cane, unlike the banana, cannot be destroyed by a hurricane, and thus it offered a steady field for labour when such calamities occurred. Nor does he see any reason why the industry should be abandoned, but the business of manufacture should be separated from that of cultivation, and the planter should cultivate scientific methods. Fruit growing, which has taken the place which sugar-planting used to occupy in the commerce of the island, is a profitable industry alike to the small cultivator and the capitalists who have engaged in it on a large scale. The crop consists chiefly of oranges and bananas, and a large quantity of the latter is sent to the United States. The cultivation of rice, commenced by the East Indian immigrants a few years ago, has expanded considerably. Cocoa is being sedulously cultivated. Stimulated by the success which has attended the Bahamas experiment, planters are seeking another string to their bow in the fibre industry.

THE QUARTERLY SALES OF CINNAMON.—The third series of public sales of cinnamon for this year was held last week, when of 1,460 bales, 16 parcels, 12 boxes and 44 ballots Ceylon was offered; but the market was so dull that at the commencement of the auction scarcely any bids were made, and whole marks were withdrawn almost without a price being named. Afterwards, however, as importers manifested a disposition to make concessions, the competition seemed to improve a little, though it was still far from spiritedly, for, whilst the commoner grades found buyers at somewhat easier rates, the finer sorts were more difficult to realise, and were disposed of about 1d per lb. lower than in May, leaving the general currency as follows:—Superior quality plantation at 1s 4d to 1s 5d; fine firsts at 10½d to 1s 1d, ordinary to good at 7½d to 9½d; seconds at 6½d to 10½d, finest at 1s 1d; thirds and fourths at 6d to 8½d; fifths at 5½d to 5½d, with broken in boxes at 5½d to 7d, and in ballots at 4½d to 5½d per lb. These prices may be regarded as unprecedentedly low.

RAKI.

The East Indian name for all sorts of distilled spirituous liquors, but chiefly for that procured from toddy or the fermented juice of the cocoa and other palms, and from rice. The coconut-palm is a chief source of toddy or palm-wine, and is obtained from

trees ranging from 12 to 16 years old, or, in fact, at the period when they begin to show the first indications of flowering. After the flowering shoot or spadix developed in its spathe is pretty well advanced and the latter is about to open, the toddy-man climbs the tree and cuts off the tip of the flower-shoot; he next ties a ligature around the stalk at the base of the spadix, and with a small cudgel he beats the flower-shoot and brins it. This he does daily for a fortnight, and in the trees in good condition a considerable quantity of a succulent juice flows from the cut apex of the flower-shoot. It is more or less fermented, and in four cases is usually sour, previous to that it is a favorite drink, known in India by the natives as *callu*, and to the Europeans as *taddy*. When turning sour it is distilled and converted into *raki*, known better to the Hindus as *arrak*, and to the Ougalese as *pol*, or *na-vaki*. It is probable that the use of *raki* is more widely diffused among the human race than either wine, brandy, whisky or the *American Grocer*.

ECHOES OF SCIENCE.

Mr. Edison is credited with another "big idea" in the shape of a "magnetical telegraph." Some years ago, while experimenting with his long distance telegraph on a long line, he observed singular induction noises which did not appear to have an earthly origin, but to be due to solar eruptions. Possessing a mine of magnetic iron ore at Ogdun, New Jersey, he is now arranging to run a telegraph wire round and round the mass of magnetic ore so as to form a large coil with a magnetic core. He intends to connect telephones with this wire, and hopes to hear a faint rumour of the catastrophes in the sun as communicated by the modern Helios "induction."

Mr. W. F. Stanley, the well known optician, has devised a "phonometer" chronograph for enabling a person to measure distances by observing the time between the report and flash of a gun. It can also be used for estimating the distance of lightning by timing the flash with the clap of thunder, and allowing a quarter of a mile (333 metres or over 1,000 feet) for every second of the interval.

In the *Philosophical Magazine* for July M. S. Tolver Preston proposes to make an acoustical thermometer. It is well known that a tuning fork of a certain vibrating period will at the normal temperature vibrate in resonance with a tube possessing a certain length; but the note of a resonance tube varies according to the temperature of the air or gas it encloses. Hence if the tube is placed near a heated body so as to change its temperature, the same fork will no longer vibrate in resonance with it. There are two obvious ways of utilising this idea. Either the resonance tube should be telescopic, so that its length can be varied as its temperature varies, and in that case the same tuning fork will serve. Or, if the tube is unaltered, an adjustable tuning fork can be used to find the temperature.

M. M. Fricourt and Hesse, of 23, Rue des Ecoles, Paris, have brought out a useful little pyroscope for indicating when a certain high temperature is reached in a furnace. The device can be used to tell different temperatures between 1,150 deg and 1,700 deg. centigrade. It consists of a little cylinder of refractory material which fuses at the temperature in question. They have been carefully calibrated and are said to be very accurate.

It is well known that the bacillus of tuberculosis is often found in places lately occupied by consumptive persons. Hor Prusnitz, of Berlin, has lately collected the dust from the railway carriages used to convey such patients to Meran, and inoculated guinea pigs with it. Three out of four of the animals became infected with the disease; and were killed after ten or twelve weeks. The author supposes the number of the bacilli in the dust to have been small, but the fact nevertheless shows the necessity of disinfecting such carriages.

The practice of placing green boughs of the eucalyptus or blue gum tree in sick-rooms as a disinfectant is growing in Australia. Dr. Urgenven states that if placed under the bed in cases of scarlet fever they will thoroughly disinfect the couch and every article in the room. The volatile scent has also a favourable influence on consumptive patients, as an antiseptic and sedative, tending to promote sleep.—*Globe*.

ARTIFICIAL RAIN.

The manufacture of rain has, for longer than it is easy or pleasant to remember, ceased to be of the slightest practical interest in this country. If anybody would patent an invention for the manufacture of sunshine and dry weather, even if it were no more than the Laputians got from cucumbers, he would deserve a statue. But we must not be so selfish as to close our sympathies to districts which actually envy the state of Cornwall, where, according to the proverb (now apparently requiring extension beyond the borders of the Duchy) it rains once every day except on Sundays—when it rains twice. In Texas, it seems, they have been cloud compelling with startling success. In a district where for more than three years no rain has fallen save in very occasional small showers, and under atmospheric conditions considered incompatible with rain enough to melt a pinch of salt, an explosion of oxygen and hydrogen from five balloons at various heights brought a sharp clap of thunder, followed by heavy rain within about five hours. For five hours the rain went on, displaying a beautiful rainbow at sunrise; the first recorded instance, so far as we are aware, of the manufacture of a real rainbow. The details of the whole process are minute; they are based, it need not be said, on the constant experience of rain after big battles, and the continual aerial explosions in Texas no doubt cheated the spirits of the storm into thinking that they were called in to assist at a favourite and familiar human pastime. The question of course remains whether they will always consent to be tricked into thinking that there is a big fight when there is nothing of the kind. Meanwhile it is gratifying not to live in Texas if nightly bombardments of dynamite and explosive gas are to be among the phenomena of practical farming. We have noise enough of our own, as things are; and happy therefore is the land whose rain, like the poet, is born, and not made.—*Globe*.

PAPAIN: THE VEGETABLE PEPSIN.

It is one of the concomitants of the advance of human civilization, and perhaps a form of the Nemesis that follows man's neglect of nature's dictates, that as his power over the material increases and as he accumulates wealth and knowledge his physical being tends to undergo a kind of retrogression, and becomes less able to bear the strain imposed upon it by an active and almost unwearied intellect.

Thus it is that one of the characteristic features of the age is the number and variety of the devices for remedying the defect alluded to, sought after and introduced, prominent among which must be classed the ever increasing array of preparations for facilitating digestion, and remedying the evils resulting from confused and sedentary habits of life, combined with hurried and unnatural systems of supplying the severely taxed frame with nutriment.

Of artificial digestive agents few have been more conspicuous than the pepsins, which being natural peptonizing substances, are apparently most suited to enhance the functional activity of an infecbled stomach. It is, however, well recognized that pepsin is not a definite body and that, as a matter of fact, its nature will vary according to the methods of pre-

paration; it seems to be further inevitable that, by whatever process it is isolated, a considerable proportion of mucus and similar substances will be present.

The fact that pepsins are of animal origin, has been the source of some amount of repugnance to their use, both on the part of patients and of physicians; the tendency of modern medicine has been to abandon the internal employment of members of the animal *materia medica*, and against this tendency the introduction evidently militates. Again, it has been pointed out, that the excretion of ptomaines or cadaveric alkaloids ceases in the animal body simultaneously with the arrest of the vital functions, so that it is not at all impossible that carelessly made specimens of pepsin might be contaminated with animal ferments or the products of their action upon the devitalized tissues. This danger is the more probable as consistently with the preparation of an active substance, sufficiently high temperatures cannot be employed in the isolation of the digestive agent to destroy the ptomaines possibly present.

In view of these objections to pepsin and the allied agent pancreatin, a good deal of interest was excited by the earlier accounts of the wonderful properties of the fruits of the papaw tree, a native of tropical America, which was credited with the power of disintegrating and more or less completely digesting flesh simply hung beneath its branches.

Carica papaya, belonging to the natural order papayaceæ, is a tree which grows to about 20 feet in height and 2 feet in diameter. It is easily and quickly raised from seed, attaining a thickness of 1 foot by the third year and commencing to decay during the fourth or fifth year. The straight and undivided stem is herbaceous and soft, though it develops an external layer of fibrous tissue; as might be expected from the rapidity with which it grows, the trunk is hollow, though at irregular intervals it has more or less dense, imperfect sops. The newer parts of the stem are green, but as they age become greyish; towards the top it also bears the scars formed by the falling off of leaves, which are arranged in a kind of umbellate canopy.

The large palmately cleft leaves are borne upon long petioles, from the bases of which the pale yellow flowers originate. Like other species of the same order the flowers of the papaw are unisexual. The staminate flowers are borne upon a long peduncle in a racemose form, while the pistillate flowers are sessile.

The tree continually flowers and simultaneously bears fruit, the latter ripening at the lower part of the crown of foliage while the flowers are just opening at the apex. The flowers, as also some other parts of the plant, resemble Indian cress—the nasturtium of the garden—in order and taste.

The fruits are somewhat melon-like in form, or they may be more ovoid and pointed at the apex. When first formed they are green, but as they mature they become yellow or dull orange colored. A large fruit is said to sometimes attain a weight of 10 pounds. The rind is thin, and within it is the yellowish flesh, with a pleasant sweet taste, enclosing a cavity containing the dark brown or black seeds.

By the natives of the districts where it grows the fruit of *Carica* is largely consumed and regarded as highly nutritious. The milky juice of the unripe fruit and the powdered seeds have the reputation of being powerful anthelmintics, and it was further reported, that the former had the property of softening the toughest meat when boiled with it for a short time. Some parts of the plant were esteemed as vulneraries, and the juice of the ripened fruit was said to be useful in removing freckles and spots from the complexion.

These reports naturally attracted considerable attention, and the juice was subjected to analysis by a number of chemists. Vauquelin found that the juice resembles animal albumen in its characters, and Wittstein stated that it contained a ferment which had a most energetic action on nitrogenous substances.

The leaves, like most other parts of the plant, yield a neutral, yellow, milky juice, with a sharp bitter taste, which by the addition of sugar, glycerine, ethe-

or chloroform may be readily preserved. Milk is at first coagulated by it, and subsequently changed to an aqueous liquid. Upon albumen, meat, and blood fibrin its effect is to soften and dissolve; the best temperature for effecting this is, as appears from experiment, 30° to 40° C. It was also found to kill and practically dissolve tania, ascarides and other intestinal parasites.

From the milky juice of the fruit an active principle, papain, is isolated, which occurs as an amorphous white, or yellowish white powder, odorless, and with a scarcely perceptible taste. The composition of the substance is not yet made out, but it indicates on ultimate analysis a content of 10.6 per cent. of nitrogen. Papain is soluble in water, and 0.1 part will dissolve 10 to 20 parts of blood fibrin. The aqueous solution is rendered turbid by boiling, and is precipitated by alcohol, by acetate of lead, by tannin, by nitric acid, etc.

This principle has been proved to possess the peptonizing properties of the juice in a very high degree of concentration, and the experiments of careful observers have shown that papain, in concentrated solution, will dissolve more meat-fibrin or coagulated albumen than will pepsin in the same time. It must also be pointed out that the vegetable principle differs from the animal substance in that first, it is most active in the presence of a small quantity of fluid, and secondly, it is almost equally effective in acid, neutral, or alkaline solutions.

One of the first uses to which the solvent powers of papain were first put in European medicine was for the breaking down and solution of the false membranes of diphtheria. It is used in 5 per cent. solution, and painted or sprayed on the affected parts. Asch, Kohts, Oertel, Rossbach, Schaffer and others used such solutions, and found them to be very successful. Dr. Jacobi, president of the New York Academy of Medicine, used papain in several cases of diphtheria or croup, and observed that its local application was followed in a few hours, or at the most days, by the disappearance of the membranes. Similar experience is recorded by Prof. Croner, Dr. J. B. Bromwell, of Washington, and other authorities. Dr. J. B. Richardson characterized it as the best and most rapid solvent for diphtheritic membrane he had used.

It was in virtue of the same solvent property that the principle was recommended and employed in the treatment of the various affections of the skin associated with a thickening of the epidermis and with the formation of crusts. Drs. McKenzie and Johnston extended its employment by applying a 5 per cent. solution, with half the weight of sodium bicarbonate, to the clearing out of the middle ear when it was plugged with masses of wax, or epithelium, or morbid secretion that syringing could not remove.

The property already mentioned of softening and more or less peptonizing flesh and fibrin, at a temperature of 30° to 40° C., evidently indicates its adaptation to internal administration—in doses of 1 to 5 grains—as a means for relieving an enfeebled stomach of part of the work of digestion. It is further noteworthy that, besides exerting its peptonizing action on the albuminous and fibrinous contents of the stomach, papain increases the secretion of the gastric juice and prevents the fermentation of the food. By virtue of these properties, it has been given with considerable success in the treatment of gastric catarrh, and in dyspepsia, while in dysentery and the chronic diarrhoea of infants it has also proved a valuable remedy.

Perhaps one of the principal fields of usefulness in which papain has been widely employed is in the expulsion of intestinal parasites. A number of authors have recorded cases in which its administration has been followed by the discharge of tania, ascarides, etc., in a shrunken and partly digested condition. Unlike a majority of so-called anthelmintics it is not dangerous to the patient, nor is it unpleasant to take. It must be remembered that although papain destroys the parasites, it does not directly expel them from the body; this must be effected by following the dose of papain with a laxative or mild purgative.

In conclusion attention should be called to the necessity of exercising care in the selection of brands of papain, as there are many kinds which are almost destitute of peptonizing power and therefore, useless for the purposes indicated above. The value of a good specimen can be readily estimated by digesting 100 grains of finely minced raw lean beef with 1 grain of the papain and 1 oz. of distilled water containing 2 grains of hydrochloric acid or bicarbonate of soda. After 20 minutes' digestion at 100° F. (with assiduous stirring) the liquid should be strained through muslin, the undissolved residue washed, dried at 212° F. and weighed. Allowing 75 per cent. for moisture in the raw beef, from 60 to 90 per cent. of the meat should be dissolved.—*Notes on New Remedies.*

EFFECT OF CHEAP ALUMINIUM.—“What will be the effect of this reduction in price (to 50c. per pound),” says the *American Manufacturer*, “remains to be seen. We do not believe that aluminium will have the extensive use in certain directions which was predicted for it, owing to its lightness and tensile strength, but there is no doubt that for many purposes, as for covering buildings, the manufacture of tableware and hardware, the production of kitchen utensils, etc., there will be a market that will consume all that can be made in the near future, if it can be produced in quantities and sold at 50c. a pound. The German Government has been in the market for twenty tons of aluminium for utensils for the kits of soldiers. We question, however, if any quantity of aluminium has ever been made so that it can be sold at a profit at 50c. a pound. No doubt some method or a modification of a known method will be discovered that will permit of its sale at a profit at 50c. a pound, if not at 25c., but that day is not yet.”—*Bradstreet's*, Aug. 15th.

THE MURUNGA OR DRUMSTICK.—A paper was recently read before the Bombay Natural History Society by Surgeon Major K. R. Kirtikar, I. M. D., entitled “Notes on a Rare Fungus Found Growing on the Drumstick Tree.” The description is accompanied by a plate. From the remarks we quote as follows:—

The Drumstick tree is a familiar figure in the Konkan fields and kitchen gardens. It is largely cultivated for its twisted trilobate foliules wrongly called “pods,” which contain a rich fleshy pulp. This pulp when cooked with butter, salt and pepper yields an agreeable and by no means unwholesome dish. Its root is used in the place of Horse-raddish at English tables in India.* Though a little coarse in fibre, the scrapings of the root are quite as good a substitute as one could expect to have in point of flavour and pungency. The flavour and pungency are due to an essential oil which is abundant in the loose parenchyma of the bark of the *Moringa*. The soft and porous woody tissue also contains this essential oil. No wonder then that any parasite throwing its mycelium on its most vitally active cells should imbibe the essential oil and retain it in its own tissue. * * *
